WE publish another communication from Dr. Abrath of Sunderland on page 632. In reference to it, we have only to repeat that the advertisement by a medical practitioner in a public paper of his private scale of fees and charges is opposed to the generally accepted notions of professional propriety in this country; and Dr. Abrath need only refer to the files of any medical newspaper, to make himself aware that such infractions of medical etiquette have not failed to be blamed when from time to time brought to editorial notice in respect to other persons and on other occasions. That such a practice would involve the striking off the *Register*, or taking away the licence of anyone who resorts to it, has not been suggested in these columns, nor has anything been said to warrant this suggestion. That is an extreme measure reserved for offences of a very serious grade indeed, and, so far as we know, has never been done except for an actual breach of the law of a flagrant kind, or for some most disgraceful professional offence. There is nothing to warrant any such suggestion in Dr. Abrath's advertisement, which, although it offends against accepted professional rules, and thus calls for reproof, is by no means of so serious a character as to justify any such action. We regret, therefore, if any one has distorted our censure of Dr. Abrath's advertisement into any such implication. Still more improper would it be to make any such suggestion to patients. We know nothing, however, of any quotations of our observations, or of Dr. Abrath's private affairs; and it is unnecessary to add that our comments, far from being "malicious", are made as a matter of editorial duty upon a public document, and in accordance with long accepted and time honoured rules in the profession. In mentioning the Council of the Apothecaries' Society or of the British Medical Association as a professional tribunal to whom we should willingly see Dr. Abrath refer the comments which we have made upon his advertisement, we added that we should willingly accept any other respectable professional authority, such, for example, as the Medical Faculty of his own University of Heidelberg; to whose judgment in the matter, if he chose to refer it, we shall be equally happy to give publicity. To the irrelevant matter in these letters, including Dr. Abrath's opinion of the British Medical Association, we need not refer.

#### MATERNAL AND FETAL MEDICATION.

THE influence on the infant of medicines, particularly narcotics, administered to the mother during pregnancy and labour, to which attention was directed at the last meeting of the Association by Dr. McClintock, has been the subject of discussion recently in America, and has called forth diverse opinions from men eminent in the profession there. The editor of the *Ohio Medical Record*, in referring to them, premises that some interesting experiments upon this same subject were made during the latter part of the year 1875, by Dr. Benecke (*Arch. Wien. Medic. Zeitung*), with salicylic acid in half-drachm doses, administered shortly before and during labour. Among other results, he shows that "the interchange between the mother and fetus was very rapid". Salicylic acid was found to have passed into the foetal organism in forty minutes, and appeared in the urine in two hours. (See *BRITISH MEDICAL JOURNAL*, December 25th, 1875, p. 786.) Other experiments had also been made by Gusserow with iodide of potassium, which seemed to prove that foreign substances easily pass from the maternal into the foetal circulation. On the other hand, experiments made by Spaeth and Schauenstein with mercury, and by Fehling with woorara, seemed equally to prove that medicinal substances do not reach the child through the placental circulation. The discussion above referred to related specially to narcotics as being of the greatest practical importance to the daily practitioner. Drs. Barker, Peaslee, and Luck, had used morphia extensively in midwifery practice, and had yet failed to recall any deleterious effects therefrom—indeed, Dr. Luck says, one patient took upwards of thirty drops of Magendie's solution on the day of her confinement, and for ten days previously, and the child was

active and lively at birth. On the other hand, the experience of Drs. Thomas, Gillette, and others, was such as to warrant the conclusions "that morphia, when administered to the degree of producing its physiological phenomena in the mother, will invariably produce a relative condition of narcotism in the new-born infant"; and, if confirmed by further experience on the part of the profession, it ought to exclude morphia as a therapeutical resource in labour. Carefully prepared tables on the one side and on the other have been presented in the *American Journal of Obstetrics* by Dr. Luck and Dr. Gillette, showing great uniformity in the effects noted by each observer; but, singularly enough, entirely diverse the one from the other.

#### THE GERMAN SURGICAL CONGRESS.

THE seventh annual congress of the Society of German Surgeons commenced in Berlin on Wednesday, April 10th. The proceedings were opened with an address by Professor von Langenbeck, who, in the course of his remarks, said that the society now numbered two hundred and twenty-five members, sixteen of whom had recently joined. Three members had died during the year: Dr. Paul of Breslau, Dr. von Heine of Prague, and Dr. von Linhart of Würzburg. Professor von Langenbeck was re-elected President.

#### STATISTICS OF THE INSANE IN PRUSSIA.

IN 1876, according to the information furnished by fifty-two public and seventy-three private lunatic asylums, there were 20,115 insane persons in Prussia—10,754 males and 9,361 females. As regards the diseases, 24.7 per cent. were cases of secondary mental disturbance. Melancholia furnished 23.08 per cent., mania 19.94, paralysis of the insane 10.01, and delirium tremens 7.42 per cent.

#### YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

THE spring meeting will be held on Tuesday, April 30th, at the Town Hall, Easingwold, at 2 P.M., when the following papers will be read. 1. S. W. North, Esq., on the Registration of Disease; 2. E. B. Hicks, Esq., on a few matters of Sanitary Interest from a rural point of view; 3. Dr. H. F. Parsons, on Dangers to Rural Populations from the Excrement Disposal of Towns. The members will dine together at 4 P.M.

#### MEDICAL EVIDENCE IN COURTS OF LAW.

IN a case which is exciting a good deal of attention this week, arising out of an alleged assault upon a popular actress, Mr. Prescott Hewett was quoted in court as having requested that other evidence than his own might be taken, as he declined to appear as a witness in court. It is well known that many other surgeons of similar position to that occupied by Mr. Prescott Hewett, and equally solicitous of preserving professional reputation intact before the public, have for many years adopted a similar course. We do not remember to have seen, for instance, Sir James Paget, or Mr. Savory, or Mr. George Pollock, make any appearance as medical witnesses in contested cases. Of course it may be said, and will be said, that, for the purposes of justice, it is essential that expert evidence should be forthcoming; and that, if all medical men of high reputation were to adopt a similar course, the evidence forthcoming at railway and other cases would be often of a less satisfactory character than that which even now often proves the cause of much public scandal. The force of such an observation is undoubted, and this is a consideration not to be undervalued. On the other hand, under the present unsatisfactory conditions of the taking of expert medical evidence in courts of law, it may be doubted whether, if practical protests of this sort were pretty universal, it would not more effectually than any other course lead to the desired reform by which expert evidence should be taken in an impartial manner for the information of the court. Certain it is that judges and lawyers alike concur in estimating, as a rule, very cheaply the sort of medical evidence which is now so frequent in courts of law; nor do they hesitate, both officially on the bench and on public occasions, and in private, to express a strong regret for the sort of conflict which frequently

occurs before them, and their opinion that it does not tend to increase the respect entertained for the acquirements and impartiality of the members of the medical profession. The resolution taken, therefore, by such men as Mr. Prescott Hewett, Mr. Pollock, and Mr. Savory, to decline to give expert evidence, is readily understood, and will meet with a good deal of sympathy; and, if the example were more generally followed, although it might tend in the first instance to still further degradation of medical evidence in courts of law, it might probably, by that very fact, ultimately lead to very salutary reform.

#### EXTENSION OF THE PROVIDENT SYSTEM.

THE Charity Organisation Society has appointed an officer for organising the extension and promotion of Provident Dispensaries in the metropolis. In notifying this useful step, Sir Charles Trevelyan mentions that the services of this officer are available in forming new Provident Dispensaries, or in converting Free into Provident Dispensaries.

#### TO VEGETARIANS.

PROFESSOR GUBLER, in his recent researches as to the causes of cretaceous degeneration of the arteries, has made the very interesting discovery that a principal cause lies in a vegetable diet, and thus explains the frequency of cretaceous arteries among the French rural population at the early age of forty. This is the more important because it is well understood that "a man is as old as his arteries", and that chalky degeneration of the arteries is the most fatal kind of premature senility. Further proof he finds in the fact that the Trappists, who live exclusively on vegetable food, very soon show arterial degeneration. In districts where chalky soils load the drinking-water with earthy salts, a vegetable diet acts more rapidly in affecting the arteries than in regions of siliceous formation.

#### DEATHS FROM STARVATION IN LONDON.

A RETURN issued of cases in which coroners' juries have returned verdicts of death caused by starvation or accelerated by privation in the metropolitan district during the year 1877 shows that the total number of such deaths was seventy-one, of which forty-seven occurred in the central division of Middlesex, twenty-two in the eastern division, one in the city and liberty of Westminster, and one in the Greenwich division. No such deaths were reported in the western division of Middlesex, city of London and borough of Southwark, Duchy of Lancaster (Middlesex and Surrey), Her Majesty's Tower of London, the verge of the royal palaces, and the New Wandsworth Division.

#### THE LONDON FEVER HOSPITAL.

THE report of this hospital shows that, during the year 1877, 629 patients were treated, as against 730 in 1876. The mortality in all cases refers to patients treated to the termination of illness. Of scarlet fever, there were 406 cases, of which 31 died, or 7.65 per cent.; of enteric fever, 119 cases, of which 19 died, or 17.5 per cent. The low mortality of scarlet fever is, perhaps, to be explained by the comparatively large number admitted with this disease after twenty years of age, when it is less common to meet with fatal cases. Eight cases of typhus were admitted, of whom four died. Of measles, there were 56 admissions and two deaths; one or two cases of erysipelas febricula and mumps, and 45 cases of other disease. At the present time, when so much is being attempted in preventive medicine, one reads with regret the following extract from this report. "The number of admissions into the private wards set apart for patients of a higher position who are able to pay for their accommodation, was twenty-seven." These small numbers show that the advantages of this department of the hospital are still insufficiently known to the public and, we would add, to medical men. According to Rule 2 of the hospital, any person can be admitted on a certificate signed by any physician, surgeon, or apothecary, stating the disease to be fever of a contagious nature, or likely to become such. Fever and small-pox are now only too rife in London, and one cannot too strongly impress on medical practitioners

the fact that there is a hospital in London at which non-pauper cases of contagious fever can be treated, whatever the grade of society from which they come; and, were this once well known, we should cease to hear of epidemics of the more usual contagious fevers arising from servants and school-children being sent to their homes at a time when there is well grounded suspicion that they are sickening for, if not actually suffering from, a contagious fever.

#### A NEW, CHEAP, AND SELF-GENERATING DISINFECTANT.

UNDER this title, Dr. John Day of Geelong, Australia, recommends for use in civil and military hospitals, and also for the purpose of destroying the poison-germs of small-pox, scarlet fever, and other infectious diseases, a disinfectant ingeniously composed of one part of rectified oil of turpentine, and seven parts of benzine, with the addition of five drops of oil of verberna to each ounce. Its purifying and disinfecting properties are due to the power which is possessed by each of its ingredients of absorbing atmospheric oxygen, and converting it into peroxide of hydrogen—a highly active oxidising agent, and very similar in its nature to ozone. Articles of clothing, furniture, wall-paper, carpeting, books, newspapers, letters, etc., may be perfectly saturated with it without receiving the slightest injury; and when it has been once freely applied to any rough or porous surface, its action will be persistent for an almost indefinite period. This may, at any time, be readily shown by pouring a few drops of a solution of iodide of potassium over the material which has been disinfected, when the peroxide of hydrogen which is being continually generated within it will quickly liberate the iodine from its combination with the potassium, and give rise to dark brown stains. It may be applied with a brush or a sponge, or, if more convenient, as is the case with certain articles, such as books, newspapers, and letters, it may be simply poured over them until they are well soaked; they may then be allowed to dry, either in a warm room or in the open air.

#### RESPIRATION AT HIGH ALTITUDES.

AT a recent meeting of the Royal Society, Dr. William Marcet communicated a paper on "An Experimental Inquiry into the Function of Respiration at Various Altitudes". His experiments were mainly undertaken with the view of inquiry into the state of the respiration of tourists at various altitudes, and under the different circumstances met with on Alpine excursions. Pettenkofer's method was adopted in the estimation of carbonic acid, and the experiments were many in number. The ori-nasal mask worn to collect the air breathed out, and the India-rubber bags that received the breath, were described. Dr. Marcet confirmed previous experiments in the fact that the quantity of carbonic acid breathed out is greater after food has been taken; and in his experiments on respiration at high altitudes, he endeavoured to neutralise the effect of food by taking an early breakfast and a late dinner, and doing the climbing between the meals. Experiments were made at the Breithorn, 13,685 feet; St. Theodule, 10,899 feet; the Riffel, 8,428 feet; St. Bernard, 8,115 feet; and the Lake of Geneva, 1,230 feet. In experiments made while sitting, Dr. Marcet finds that there is an increase of carbonic acid breathed out as a person rises above the sea on a mountain excursion, and that this is due to the fall of the atmospheric temperature, and to the cold produced by increased evaporation from the body, arising from the diminished pressure of the atmosphere. In short, more carbonic acid is formed in the body to counterbalance the influence of cold from the causes just mentioned. If on ascending to a higher level we should find the same atmospheric temperature as we left at the lower station, still an increased amount of carbonic acid would be expected, on account of the cold due to the greater cutaneous and pulmonary evaporation. Dr. Marcet experimented in a similar manner while ascending hills. Walking up rapidly over rocks and grass patches yields most carbonic acid, the amount being 3.155 grammes per minute, which, he said, was attended with the inhalation of the largest volume of air breathed. Ascending quickly at the height of St. Theodule caused a considerable elimination of carbonic acid through the lungs, amounting to 2.972 grammes.

On the other hand, walking leisurely up-hill at the St. Bernard gave rise to the production of no more carbonic acid than quick walking on the level ground at that same station.

#### THE VITAL STATISTICS OF ITALY.

IN Italy during the year 1876 there were 225,000 marriages, 1,083,000 births, and 796,000 deaths, the population being 27,700,000 persons. Of the marriages, the largest number, compared with the population, occurred in the southern provinces, or *compartimenti*, in Basilicata, where there were 10 per 1,000, and Apulia, where the proportion was 9 per 1,000. In the province of Rome the number was the smallest—namely, 5.59 per 1,000, and after Rome in Sardinia, where it was 6.87 per 1,000. The fecundity of marriages stands, however, in inverse ratio to their number, being greatest in Rome and Sardinia, and smallest in Basilicata. In Basilicata, again, the fewest marriage certificates were subscribed by both parties—viz., only 3 per cent. In Rome 30 per cent. were subscribed, but education is most advanced of all in Piedmont and Lombardy, where 55 per cent. and 45 per cent. respectively wrote their names upon the certificate. Of cases in which neither the man nor the woman contracting could write, there were 80 per cent. in Basilicata, while there were only 13 per cent. of such cases in Piedmont, 24 per cent. in Lombardy, and 23 per cent. in Liguria. The percentage in Rome was 38. Education is, however, advancing in Italy as elsewhere; for while there were only 34 per cent. who could write their names on the marriage certificates in 1872, there were 37 per cent. in 1876. Of the births, the largest percentage of legitimate children occurred in Piedmont, Liguria, and Lombardy—viz., from 95 to 97 per cent. of all children born. The illegitimate numbered only 2.17 to 3.50 per cent., and the children exposed in Lombardy only .68, and in the other two departments about 1.30 per cent. In Rome, on the contrary, the percentage of legitimate births was smallest—namely, 81 per cent., and of illegitimate largest, 15 per cent.; but there were, again, only 3 per cent. of the children exposed, while in Sicily, for instance, 5 per cent. were exposed. In Sicily, while the number of illegitimate children born was 3,000, there were 6,000 exposed, so that 3,000 of these were recruited from those born legitimately.

#### LEGALITY OF POST MORTEM EXAMINATIONS.

A CASE has recently occurred in France, in which the right to examine a dead body without the consent of the relatives and executors has been brought as a question before a court of law. The widow P. died in the hospital of Montpellier. Her relatives desired to see the body, and they found that one of the feet had been cut off. The missing foot, at the request of the relatives, was produced and replaced on the leg of the corpse. In explanation, it was stated that the widow P. had died of a peculiar disease of great interest in a scientific point of view, and that the Professor of Pathology had found it necessary to make a necropsy and had removed the foot, as it was the seat of an inflammatory lesion the nature of which it was necessary to determine. The relatives of the deceased widow protested against these proceedings, and affirmed that from the date of the death they had given the sister of the ward notice that they would reclaim the dead body. They summoned Professor E., who had conducted the *post mortem* examination, before the civil tribunal, and claimed from him damages for his interference with the body without their permission. The civil tribunal, in an elaborate judgment, decided against the plaintiffs, and condemned them in the costs of the action, chiefly on the ground that, under an edict of March 1707, the bodies of persons dying in hospitals in which they have received gratuitous attendance shall be at the disposal of the professors for surgical and anatomical examination under certain restrictions. There was, further, no proof that the notice to the ward-sister had been communicated to the professor (*Chronique des Tribunaux*). As a rule, the hospital authorities in England claim a right to examine the bodies of those who have died in the hospital, not for the purposes of dissection, but to determine and explain the cause of death when this is absent. In some cases, the relatives sign a paper to this effect before the applicant is admitted as a patient. Such a right should in all cases be conceded.

## SCOTLAND.

THERE were eighty-three deaths from measles and whooping-cough in Edinburgh during the month of March.

At a meeting of the St. Cuthbert's Parochial Board, last week, the Inspector reported forty-four cases of defaulters under the Vaccination Act, and the usual proceedings were ordered to be taken against them.

It is understood that Dr. Heron Watson, whose term of office as a Surgeon to the Edinburgh Royal Infirmary has expired, retains two wards as long as the present buildings are occupied. It is rumoured that the managers are about to appoint a third Assistant-Surgeon to the institution. The election is likely to take place shortly.

THE report, by the Medical Officer of Edinburgh, of the health of the city for the month of March shows that, during that period, there were no deaths from typhus, diphtheria, or small-pox, and only four from typhoid and seven from scarlatina. On the other hand, the deaths from measles were 60, and from whooping cough 23. The total mortality from zymotic diseases was 96, or at the rate of 21 per cent. of the total mortality. The deaths from these diseases, for the quarter ending March 31st, were 251, or 18 per cent. of the total mortality, as contrasted with 78 deaths, or 6.78 per cent., in the corresponding quarter of last year. The total mortality of the quarter was at the rate of 26 per 1,000, the average for the past five years being 23.76. The death-rate during the same period was equal to an annual rate of 33.5 per 1,000 of estimated population.

## ST. ANDREW'S UNIVERSITY.

THE ceremony of graduating those who have passed in Medicine and Arts took place on Thursday, the 18th, in St. Mary's College, St. Andrew's; Principal Tulloch presided. The following received the degree of M.D.: Oliver Codrington, Chatham; W. T. Colby, Malton, Yorkshire; A. Eteson, Watford, Herts; S. Grose, Staff-Surgeon R.N., Melksham, Wilts; F. Hall, Leeds; H. Hicks, Hendon, Middlesex; A. T. McGowan, Clifton, Bristol; W. Whalley, Bradford; H. Woolton, London; H. B. Wynter, Wandsworth. The following were presented with the degrees of M.B., C.M.: J. S. Mackay, Edinburgh; J. H. Rea, Belfast; J. Dearden, Church; C. P. Kenpe, London.

## DR. ALLEN THOMSON.

THE portrait of Dr. Allen Thomson, painted by Sir Daniel Macnee, P.R.S.A., was presented to the Glasgow University authorities, and a *replica* to Mrs. Thomson, by the citizens, in recognition of his services to science, before a large audience, in the Lower Hall of the University, on Wednesday, April 17th. In making the presentation to the University authorities, the Lord Provost remarked that Dr. Thomson, who had attained a place in the foremost rank of modern scientific men, had graduated at Edinburgh, his native city, forty eight years ago; that he had been a professor, first in Aberdeen, then in Edinburgh, and lastly in Glasgow, for thirty years. During this long term of office, which had only expired on his retirement quite recently, he had taken an active part in all academic matters, as they might judge from the fact that he was selected to cut the first sod when the works connected with the new University were commenced; and he hoped he would take part in an equally interesting ceremony, when, through the princely munificence of the Marquis of Bute, the building should be completed. Principal Caird, in acknowledging receipt of the portrait, expressed the utmost gratification that the University authorities should possess this masterly work, which not only gave the form and features, but something of the mind and spirit of the man—something of the cultured intelligence, of the high bred wisdom, of the man of science; of the sagacity and ripe experience of one who was pre-eminently wise in counsel, and the no less genial, kindly, unselfish, and tried and trusted friend. In acknow-

ledging the present of the *replica*, Dr. Thomson expressed his great pleasure in having obtained the approbation of the citizens, his deep sense of the honour conferred on him, and his extreme satisfaction with the manner in which the portrait had been painted by his friend Sir Daniel Macnee.

## MUNIFICENT BEQUESTS.

THE late Mrs. Bell of Balgray has left to the University of St. Andrew's the sum of £1,000, for the foundation of a Scholarship in Arts or Medicine, to be called the Patrick Kidd Scholarship, in memory of her father. The residue of the remainder of Mrs. Bell's estate, about £9,000, will be divided among the poor of certain parishes, the Dundee Royal Infirmary, and other charitable institutions, in the proportion of from one to three-tenths to each; the Infirmary receiving three-tenths. The residue of the estate of her sister, Mrs. Byers, to the same amount, is divided among similar institutions, among which the Perth Infirmary receives three-tenths.

## EDINBURGH BOTANICAL GARDEN.

A REPORT for the year 1877, by Professor Balfour, the Regius Keeper of the Garden, has been issued recently. From it we learn that Inverkeith House, the future residence of the Regius Keeper, cannot be made habitable before the end of the approaching summer. A most important want in the house is a room for a library, especially botanical. The Keeper has still to complain of want of funds to carry on the ordinary work of the Garden; the total sum allowed annually for this purpose being £1,400: an extra sum of at least £300 annually is required for the ordinary working expenses of the Garden. There is no botanical garden of the same area, and used to the same extent for teaching purposes, which is kept up on so small an outlay. The accommodation of the students who attend the lectures on botany is still in the same inefficient state as it has been for some years. The class-room can at most accommodate 230, and last summer the number attending the class was 389. Petitions for increased accommodation have been, during three years, sent to the Office of Works, one of the petitions being signed by three hundred students of medicine. While the Professors of the Medical Faculty in the University are getting increased accommodation by the aid of a grant from Government, the Professor of Medicine and Botany, whose class last year was third highest as regards numbers, is compelled to lecture in an overcrowded room, the vitiated air of which is injurious to the health of both lecturer and pupils. The Garden stands in need of an aquarium and fern-house, in order to complete its means of teaching. The number of visitors to the Garden in 1877 amounted to nearly 80,000. The number of fresh specimens of plants used for lectures and demonstrations during the year was 48,820. Plants and seeds have been forwarded to thirty-five gardens at home and abroad.

## IRELAND.

At a meeting of the Senate of Queen's University, held on Wednesday last, Dr. Duffey was appointed an Examiner in Materia Medica.

DR. STRAHAN, dispensary medical officer of No. 2 subdistrict, Belfast, having resigned, Dr. McKee has been appointed *locum tenens* until the vacancy is filled up. The election will take place on the first Monday in May.

DR. BLAQUIERE, who is the medical officer of the Ballynoe Dispensary District, Fermoy Union, was last week thrown from his horse, and sustained serious injury, several ribs being broken.

## LIMERICK DISPENSARY.

At a meeting of the Dispensary Committee last week, an election for a dispensary medical officer to No. 1 District took place, in the vacancy occasioned by the resignation of Dr. Carey. There were two candi-

dates—Drs. Meehan and O'Connor—the latter gentleman being appointed by a majority of votes. Dr. Carey, who had served for forty-seven years, has been recommended for a retiring allowance equivalent to two-thirds of his late salary.

#### SMALL-POX IN LIMERICK.

THREE additional cases were admitted into the Workhouse Hospital last week, two of the patients being privates in the Royal County Limerick Fusiliers. As the barracks are very close to the workhouse, the regiment will be placed in tents at the King's Island, and their quarters at the Royal Barracks thoroughly disinfected.

#### STEWART INSTITUTION FOR IMBECILE CHILDREN.

AT a meeting of the Managing Committee of this institution last week, Mr. Pascal P. Law handed over securities amounting to £835, making, with £3,165 given on February 25th last, the sum of £4,000, to form the nucleus of a fund for an additional wing to the new buildings, which will shortly be opened at Palmerstown, County Dublin. A bazaar in aid of the funds of the charity will be held early next month.

#### CORK STREET FEVER HOSPITAL.

AT the meeting of the Managing Committee of this hospital last week, it was reported that the accommodation available for small-pox patients was virtually exhausted, there being one hundred and thirty-two cases of the disease, as well as twenty-eight fever cases, in the hospital. Fortunately, the Kilmainham auxiliary sheds are now ready for the reception of small-pox patients, either acute or convalescent cases. In this way, the pressure on the Cork Street Fever Hospital has, it will be observed, been timely removed. But only barely so; the Board of Guardians of the South Dublin Union having taken no satisfactory steps to fulfil their duties in providing hospital accommodation, until threatened with dismissal by the Local Government Board.

#### THE HOSPITAL FOR INCURABLES.

THE Misses Brooke, sisters of the late John Brooke, Esq., Q.C., whose liberality to the charitable medical institutions of Dublin has been noticed by us on former occasions, have given a sum of £500 to this hospital, in addition to a former contribution of £200 to the same charity.

#### ST. MARK'S OPHTHALMIC HOSPITAL.

THE bazaar recently held for the benefit of this hospital realised a sum of £518. Considering the number of bazaars for charitable purposes held about the same time in Dublin, this result must be looked upon as very gratifying and satisfactory. The Misses Brooke have also given a second donation of £100 in aid of the Building Fund of the hospital.

#### HEALTH OF DUBLIN: QUARTERLY REPORT.

IN the Dublin Registration District, during the quarter ending March 30th, the births registered amounted to 2,526, being equal to an annual ratio of 1 in 31.1, or 32.1 in every 1,000 of the population; and the deaths registered to 2,463, affording an annual ratio of 1 in 32.0, or 31.3 per 1,000. The death-rate, it will thus be seen, was not much below the birth-rate; the former being 31.3 and the latter 32.1 in every 1,000; but it was, however, slightly less than the average rate of the first quarter of the last ten years. The deaths from zymotic diseases amounted to 431, the mortality from the seven principal being equal to an annual death-rate of 4.3 per 1,000 inhabitants. Of these, small-pox caused 57 deaths; fever, 69; whilst the deaths from measles and its complications, which had been very numerous throughout the greater part of last year, 147 having been registered in the December quarter, fell in the March quarter to 75, of which one-half were recorded in the month of January. Croup produced 33 deaths; scarlet fever, 20; diarrhoea, 33; diphtheria, 7; dysentery, 5; erysipelas, 3. One hundred and seventy-four deaths in children were ascribed to convulsions; and 107 deaths attributed to heart disease. Diseases of the respiratory

organs (excluding phthisis) caused 660 deaths, or 27 per cent. of the total mortality. These deaths, owing to the prevalence of pneumonia, were 51 over the average in the corresponding quarter of the past ten years.

#### ARMY MEDICAL DEPARTMENT.

THE following memorandum, in reply to the late Secretary of State for War's circular to the Medical School, has been forwarded from the Professors of the School of Physic.

"At a meeting of the Professors of the School of Physic in Ireland, held in Trinity College on April 15th, 1878, it was resolved (in drawing up a reply to Mr. Secretary Hardy's letter of March 21st last) to mention the following as the principal reasons which prevent the students of Trinity College from competing in larger numbers for the Army Medical Service:—1. The feeling of distrust produced by the frequent changes in warrants and regulations has caused a reluctance on the part of the medical students of Trinity College to enter a service in which they are unable to calculate with certainty on their future career and treatment; 2. The recent short service system, by which a medical officer is liable to compulsory retirement at the end of ten years' service; 3. The disadvantage at which medical officers are placed, as compared with other officers, in respect to several matters, such as sick and ordinary leave, exchange, and barrack privileges. In addition to the foregoing reasons, the medical students of Trinity College are of opinion (whether rightly or wrongly the professors do not undertake to say) that the abolition of the regimental system has seriously diminished the social and other attractions of the service for candidates of liberal academical education.

"SAMUEL HAUGHTON, Medical Registrar."

#### THE RIVER LIFFEY NUISANCE.

WITH the return of dry and warm weather, the foul emanations and "abominable stench" from this open sewer are making its existence the subject of annually recurring complaint by, and discomfort to, the citizens of Dublin. The foreshore of the river was cleansed last in the spring of 1876. Lately, in the neighbourhood of the most frequented portions of the river, the lodgment of solid sewage-matter on the banks, especially during low tides, has become most offensive. This is chiefly owing, no doubt, to the works in connection with the widening of Carlisle Bridge now in progress, and by which there is much disturbance of the sewage caused. The projecting piers of another recently erected bridge higher up the river—the smaller bridge—also tend to cause an accumulation of sewage in the angles. We are glad to see that, on the motion of Mr. Gray, M.P., the corporation have directed the Public Health Committee to consider and report as to the best means of abating the present foul condition of the river, and have authorised the Committee to incur an expenditure not exceeding £200 for such temporary abatement of the nuisance as it may think advisable.

#### PHYSIOLOGICAL TEACHING IN DUBLIN.

AT a meeting of the Council of the Royal College of Surgeons in Ireland last week, a resolution was adopted: "That steps be taken to obtain a change in the existing by-laws relating to physiology and surgery certificates." The subject was brought under the notice of the Council in consequence of an application from the Registrar of the Carmichael School of Medicine (Dr. Harvey), requesting that a certificate of attendance on a laboratory course of practical physiology should be accepted in lieu of one of the three winter courses of theoretical lectures in physiology required by the by-law. The question was referred to the Educational Committee to report as to what changes were necessary. As to the changes which we believe to be necessary, we have already clearly expressed our opinion in commenting on Dr. Harvey's letter to us on the subject in the JOURNAL of the 6th instant; viz., that a distinct course of practical physiology is a necessity of the improved teaching of the present day. Dr. Mapother's views, however, as to the teaching of practical physiology (*vide* JOURNAL, April 13th, page 551) will now, we believe, be shared in by any teacher who has had experience in conducting a practical class.

MEDICAL REFORM COMMITTEE OF THE BRITISH  
MEDICAL ASSOCIATION AND THE GENERAL  
MEDICAL COUNCIL.

ON Wednesday, April 16th, a number of the members of the Medical Reform Committee waited upon the President and several of the members of the General Medical Council, at an informal meeting held at 11 A.M. for the purpose of receiving them. The deputation consisted of Dr. Waters of Chester (Chairman of the Committee), Dr. Davey of Bristol, Dr. Wade of Birmingham, Dr. Stewart of London, Dr. Leech of Manchester, Mr. Wheelhouse of Leeds, and Mr. Nicholson of Hull.

The members of the Medical Council present were—Dr. Acland (President), Sir James Paget, Dr. Rolleston, Dr. Pyle, Dr. Storrar, Dr. Andrew Wood, Mr. Macnamara, Dr. Leet, Dr. Apjohn, Sir Dominic Corrigan, Dr. Quain, and Mr. Teale.

The PRESIDENT, addressing Dr. Waters, said: We have received this telegram from you, Dr. Waters, saying you desired to see the Council; and it has been laid before the Council. The Council have received two letters, written, it is supposed, by your colleagues.

Dr. WATERS: I am acting on behalf of the Medical Reform Committee; and, in writing the letter to the Council, I was fulfilling the instructions of the Committee, and, having full power to act for it, my letters were not read to the Committee.

The PRESIDENT: The Council requested me to ask, for its information, whom you represent. As, perhaps, your colleagues have not seen your letter, and they may like to hear it, I will ask the registrar to read the letter, because that will tell the gentlemen present what business has brought us together.

The following letter was then read.

"14, Nicholas Street, Chester, March 30th, 1878.

"Dear Dr. Acland,—In the present conjuncture of medical politics, I venture to submit to your careful consideration, as President of the General Medical Council, the Medical Acts Amendment Bill, approved and promoted by the British Medical Association. This Bill, amended as it would necessarily have been in its passage through the legislature, would, I believe, have been infinitely more acceptable to the profession and more beneficial to the public than the present Bill of the Government. I enclose with the Bill of the Association some of the reports of the Committee. The division of opinion between the General Medical Council and what is regarded as the profession in the matter of medical reform must be detrimental to the real interests of the profession which we all have so earnestly at heart. Is there no possibility of reconciling the different views held by each party, so that we might with one accord urge the Government to grant the prayer of the profession?" (Signed) EDWARD WATERS, Chairman of the

Medical Reform Committee of the British Medical Association.

"Professor Acland, M.D., F.R.S., Oxford."

The PRESIDENT: I received that communication from Dr. Waters, written as Chairman of the Medical Reform Committee of the British Medical Association; and, feeling that it was my duty to do everything that lay in my power to meet the wishes of the British Medical Association, I replied to it without expressing any opinion as to the contents of the letter, which spoke of divisions of opinion between the General Medical Council and what was regarded as the profession; and, without in any way committing the Council to acknowledge any such division of opinion, I thought it my duty at once to reply to Dr. Waters as follows.

"Oxford, April 3rd, 1878.

"Dear Sir,—I have to acknowledge the receipt of your letter on the subject of the amendment of the Medical Acts, together with the enclosures; viz., a Medical Bill (1876) and three other printed documents relating to changes in the Medical Acts. They shall all have my best attention. I trust with you that legislation may be able to rectify any anomalies or defects which can give just ground of dissatisfaction in respect of the Medical Acts. I am confident that you may rely on the best efforts of the Medical Council in endeavouring to ascertain what that legislation should be, and in seeking to bring about a successful issue.

(Signed) H. W. ACLAND.

"E. Waters, Esq., M.D., Chester."

That letter, which was written by me in the absence of the Council, I think I may venture to say, expresses the feeling of the Council since it has met. The Council has now been engaged for several days in considering the best way of amending the Medical Act Amendment Bill. I pledged myself that in my judgment the members would do

so; and they have done so certainly this last week. Then I received another letter from Dr. Waters.

"Chester, April 9th, 1878.

"Dear Sir,—I thank you for acknowledging the receipt of my communication respecting the amendment of the Medical Acts. On behalf of my Committee acting for the British Medical Association, I have to express a hope that the opinion of the General Medical Council may be taken on the subject of the distinct representation of the profession upon it. The action of the Association since 1866, when a deputation on its behalf waited on the Council, proves that the Association is in earnest in its desire to obtain [it].

"(Signed) "EDWARD WATERS,

Chairman of the Medical Reform Committee.

"Professor Acland, M.D."

The Council decided at once to comply with the request of Dr. Waters, and expressed its readiness to answer any communication he might wish to send to the Council. We received the letter on Monday; and, unless the standing orders of the Council had been suspended, it would have been impossible to comply with the request therein contained, which was, that the Council should receive the members of (I suppose) this Committee before twelve o'clock on Wednesday. Unless the Council had considerably set aside the standing orders, that was impossible. This was done; and we were able to reply on Monday night that, although it was impossible for the Council to meet to-day before two o'clock, a greater part of the Council would be present to receive you. The following telegraphic message was sent in reply.

"I cannot summon the Committee to attend a mere informal meeting." That is how the matter stands. Having said this much to the deputation, I am sure those present desire to receive in the most open manner any communication which Dr. Waters or the gentlemen present desire to make.

Dr. WATERS: There is one element which I think it would be well to lay before the Committee, that is, the letter containing the resolution of the General Medical Council to which this telegram is a reply; and I should like the letter to be read. In the meantime, perhaps, Mr. President, I should like to ask the members of the Committee whether my communications with the General Medical Council, acting on behalf of the Medical Reform Committee, are not strictly in accordance with the lines of action laid down by the Committee in all our meetings. There have been meeting after meeting of the Medical Reform Committee, the members of which are busily engaged in responsible positions in different parts of the kingdom; and, as in the case of other bodies, so in this instance, a certain power is delegated naturally to the Chairman of acting on behalf of the Committee as circumstances may arise; but in all I have done I have the knowledge that I have only been doing precisely what the Committee had commissioned me to do.

The REGISTRAR then read the letter sent, with the resolution passed on the 12th.

Dr. WATERS: May I read the telegraphic reply? "I cannot formally summon the Committee to attend an informal meeting." In the resolution, as I read it, it appeared that the Committee was not invited to meet the General Council here present as a body, but that the Council had permitted the President of the General Medical Council, with such members as might be pleased to attend, to receive me or other members of the Committee; and therefore, of course, I could not formally summon the Committee to attend as a matter of duty at this meeting. I issued telegrams, and the result has been that several members from different parts of the country—Birmingham, Leeds, Hull, and other places—have attended to-day; but I think it right also to state that some members of the Committee in London—the ex-Presidents of the Association, the President of the Association, and the President-elect of the Association—taking into consideration the terms of the resolution, do not attend. They thought it was not a meeting of the General Medical Council as a body, but merely such portion of the General Medical Council as might be inclined to attend; and therefore I have to regret that on this occasion we only have a portion of the Committee present, while many of the ancient members belonging to it are absent.

Dr. QUAIN: Before Dr. Waters proceeds further, I should like to know what his request really was. It was, as I understood, that the Council should receive him at twelve o'clock, and at no other hour.

The PRESIDENT: Excuse me; before twelve o'clock.

Dr. QUAIN: I protest against such a request. Here is a body representing the most distinguished institutions of this country. The members have a fixed time for their duties, and a gentleman writes and says, "Receive me before twelve o'clock". Why, sir, courtesy should have made him ask, "When can you receive me?" I protest against this mode of procedure. I would say that for the

Council to be asked to wait on Dr. Waters in this fashion is an insult to the Council.

Dr. WATERS: I should be sorry if it be so understood. If any feeling be imported into this matter, it will very materially prejudice the proceedings of this day.

Dr. QUAIN: There is no personal feeling in the matter; but to sit here and be upbraided for not receiving Dr. Waters at a particular time, when the fault is entirely his own—

Sir DOMINIC CORRIGAN: I beg leave to say a word in reference to the observation that Dr. Quain has made. He has taken upon himself to speak for the Council, and says that an insult has been offered to it. I do not take anything that Dr. Waters has said as an insult to the Council.

Dr. QUAIN: I did not say so.

Sir DOMINIC CORRIGAN: As a member of the Council, I dissent from that statement of Dr. Quain. I have heard nothing to justify its being said that it is an insult to the Council.

The PRESIDENT: I am sure that, be the deputation a formal committee or an informal committee, be this a formal meeting of the Council or an informal meeting of the Council, all present desire that no personal feeling should be imported into the matter. Only it would be extremely desirable, before proceeding further, to consider what has brought us together. Sir James Paget and Dr. Quain himself, and several other members of the Council, have left their duties to-day at a time when they are not called upon by the rules of the Council to come, and wish all idea of personality of any kind to be entirely dismissed, and all idea of disrespect to the gentlemen of the deputation, and for this plain reason—which is the fact—that we set aside our standing orders to bring the matter in discussion before the Council; and, indeed, it was only by the courtesy of the Council towards the President that we were enabled to depart from our ordinary proceedings to consider the matter at all; and had we not done so, Dr. Waters would not have received an answer. And an answer to what? An answer to his request that we should receive him to-day before twelve o'clock. If the Council had not gone out of its usual way to comply with this request, the meeting could not have been held at all. Therefore, gentlemen, let us understand all round that the meeting is informal in its character, and I do not know of any similar proceedings being adopted during the whole twenty years of the existence of the Council. I, for instance, came up from Oxford this morning; so that all idea of discourtesy should be dismissed absolutely. Now, we will proceed to business. Allow me to say one thing, which will possibly set the matter straight. The first letter I received from Dr. Waters was answered in the heartiest way possible, that I was quite sure the Council wished to assist the whole profession, and Dr. Waters and all others who had the interests of the public and the profession at heart, in every way they could. We were meeting to discuss a particular Bill, and we have discussed that Bill for a week. In that Bill, there is no allusion to the subject which is referred to in the second communication—not even in the first, as brought forward by Dr. Waters. And we are met, I say, for a subject this morning, for the consideration of which we have not been summoned at all, because the particular subject brought before us this morning is not contained in our Bill. Having cleared up everything, we are quite ready now to enter fully into the subject brought forward by Dr. Waters.

Dr. WATERS: I am very sorry any remarks of mine should have excited so much warmth on the part of a member whom I personally know, and for whom I have a great regard.

Dr. QUAIN: I can but express my regret.

The PRESIDENT: I trust that the business will now be proceeded with.

Dr. WATERS: I wanted to explain why it occurred that certain members of the Committee were not present. I would say, with regard to the first communication to the President of the General Medical Council, that the Bill advocated by the Association was submitted to the General Medical Council for its consideration.

The PRESIDENT: I beg to ask to what Bill you allude. Is it the Bill you forwarded to me?

Dr. WATERS: The Bill of the British Medical Association—the proposed Bill.

The PRESIDENT: Has that been introduced into Parliament?

Dr. WATERS: It was read the first time in Parliament in the year 1873. It is not before Parliament now. The Bill embodies the principle to which the Association has pledged itself for years. It was read in the House of Commons in 1873. In that Bill, the very first provisions are as regards the representation of the profession in the General Medical Council; and as on that point there was a difference of opinion, so to that point the attention of the General Medical Council should be specially directed.

Dr. ROLLESTON: May I ask on what subject there was a difference of opinion?

Dr. WATERS: The representation of the profession.

Dr. ROLLESTON: Where was the difference?

Dr. WATERS: We have for many years back been before the General Medical Council, and we have suggested that the profession should have direct representation in the General Medical Council. The Council has never accorded that desire of the profession or of the Association.

Dr. ROLLESTON: Has it expressed any opinion upon it?

Dr. WATERS: The difficulty has been to obtain a collective opinion; the question has been shelved when brought before the Medical Council.

Dr. ROLLESTON: It has then been brought before the General Medical Council, but not in my time.

Dr. WATERS: Dr. Andrew Wood was a strong advocate for the representation of the profession in the General Medical Council. This being one of the main objects of the Bill of the Association, it was natural to suppose that the attention of the General Medical Council would be directed to it, in consequence of the letter from me as Chairman of the Medical Reform Committee.

Dr. QUAIN: When was the Medical Reform Committee appointed?

Dr. WATERS: It was appointed at Newcastle several years ago, after the withdrawal of the proposed Medical Amendment Act of the Marquis of Ripon. Before that time, the British Medical Association had simply what was called a Committee on Direct Representation, and that Committee was formed with the sole view of obtaining direct representation of the profession in the General Medical Council.

Dr. QUAIN: Did that Committee resign as the result of a subsequent resolution?

Dr. WATERS: It has never resigned.

Dr. QUAIN: Or any members of it?

Dr. WATERS: No members of it.

Dr. QUAIN: I understood that a resolution was carried at a subsequent meeting, and, as I read in the reports in the JOURNAL, several members of that Committee resigned, and Dr. Waters was one of them. I never read of the reappointment of the Committee.

The PRESIDENT: Perhaps I shall express the sense of the members of the Council present when I say that it would be very desirable, as Dr. Waters has requested us to come and hear his statement, that we should hear him in full. Notes should be taken of any question we desire to ask. Our position is this: that we have come here to listen to the communication and statements that Dr. Waters wishes to make.

Dr. QUAIN: It is very desirable to know by whose authority Dr. Waters speaks.

The PRESIDENT: No doubt, Dr. Waters will give us all the information we require; and if not, we will receive information by and bye.

Dr. WATERS: We shall never get on really at this rate, if I am speaking of a meeting at Newcastle years ago, and then suddenly have to jump over an interval of time and come to the meeting at Manchester held last autumn. Dr. Quain has put a question, and I was answering him. I say, up to that meeting at Newcastle, from the time of meeting in Dublin, when the Committee was first appointed, there was simply in this Association a Direct Representation Committee, as it was termed. It had one object before it—to obtain a modification of the General Medical Council; and the Committee then, when the Bill of the Marquis of Ripon came before the Legislature, declined to accept that Bill because it did not concede what the Association prayed for, and believed to be, not its right, but the right of the profession. On the withdrawal of the Bill it was assumed by the Association—indeed, it was assumed by the members of the House of Commons at the time—that the Association had entered on a different phase; and, so far from being a Direct Representation Committee, it became converted into a Medical Reform Committee, and from the time of the meeting at Newcastle up to the present moment, it has been the Medical Reform Committee of the Association. I was Chairman of the Direct Representation Committee, and I have been Chairman of the Medical Reform Committee, and remained Chairman of that Committee without a break until the meeting last August in Manchester. The report on the Reform Committee was then brought forward as usual at the annual meeting of the Association, and it was read and accepted; but a member of the Association moved that, instead of simply going in for the whole broad features of medical reform, to which the Association has been pledged for forty-five years, the Association should simply go in for a Bill to enact penal clauses by which practitioners should be kept in what many members consider their proper places. As Chairman of the Committee, I resigned my post, and other members also resigned; and one gentleman, Dr. Stewart, is here to-day, who resigned on the occasion. Now to explain to Dr. Quain, the Committee is appointed from year to year

with power to add to its number. The Committee met. I was requested, though I resigned, to attend that Committee. I attended, and they begged me again to resume my place on the Committee. I hesitated, but, on representations made to me, I after a time resumed my place upon the Medical Reform Committee of the British Medical Association, and again became Chairman of that Committee, and in that capacity have acted ever since, summoning the Committee at such times as I thought right; and, indeed, I have summoned the members for to-day by special telegram, and the response of the Committee to my summons will satisfy Dr. Quain that there can be no doubt that, so far as any body can constitute me Chairman of that Committee, I stand here in that capacity. A crisis, as we believe, having occurred again in the matter of medical legislation, the Committee have had more than one meeting; it has had several meetings, and individual members of the Committee have taken action, and, in accordance with instructions given me, I communicated with the President of the General Medical Council. My object in doing so was to bring, if possible, united action between the General Medical Council and the profession. I believe in my heart and conscience, that there is no doubt that the Association represents the general body of the profession in this country. I believe, also, that this Medical Reform Committee, which has been appointed year after year now over a period of ten or eleven years, represents the views of the Association, and that, so far as any body of men can represent others, so does this Committee represent the Association in its collective capacity. I believe it also represents the profession, and that we have the voice of the profession of this country with us in the objects for which we are now striving. I should like to say that this Association, since the second year of its existence, has been busy in the matter of medical reform, and that it has continued to be so; that, indeed, to the Association is due the Medical Act of 1858. It is very natural for many people to think that the Association may not have played the part that we believe it has played; but, at any rate, it is certain that, in 1853, the Association drafted a Bill, regarding which Bill there waited on Lord Palmerston a deputation of numerous members of the profession. It was supported by members of Parliament, including many distinguished men, such as the late Mr. Macaulay and others; but it is not necessary to enumerate the names, because they are given in the JOURNAL of that date. In reference to that Bill, Sir Charles Hastings told Lord Palmerston that he went in for three things, viz., equal rights to practise throughout the United Kingdom—those rights have been given: the adoption of uniformity of qualification—unfortunately, uniformity of qualification has not yet been attained; and the adoption of the representative principle in the formation of the Council. Then there was the formation of a register. Now two of the objects for which the Association has striven have been obtained; that is, reciprocity, and next the register; but we have a far more important object, the having a good portal by which the qualifications of every man entering the profession shall be tested. I think that reciprocity without a good portal is conferring an advantage upon bodies, it may be, of a very inferior character, and so persons unfitted to practise the profession may, through the absence of uniformity, enter the profession and be registered as qualified practitioners and practise with impunity as regards the public generally. Now that uniformity not having hitherto been obtained, we have striven to reach it by the conjoint scheme of examination in each division of the Kingdom; and the Bill of the Marquis of Ripon gave us that. By the decision of the Direct Representative Committee, we were obliged not to accept it. Whether rightly or wrongly, we did not accept it; we were commissioned to obtain an object which was not conceded, notwithstanding the prayers of the Association, notwithstanding its representations to the General Medical Council; more than once we declined to accept it, and we did so for this reason, that we believed, if we accepted the conjoint scheme, the question of the general representation of the profession in the General Medical Council could not have been brought before the legislature. Now we still go in for the conjoint scheme, but we want, further than this, direct representation; and I think we may well come before the General Medical Council to-day to ask the members whether they do not think that there is some reason why the profession as a body should be represented in this General Medical Council. The objects of the Association are, uniformity of qualification; secondly, equal rights to practise throughout the United Kingdom; thirdly, the adoption of the representative principle in the formation of the Councils. At one time, it was thought there might be a Council in each division of the kingdom.

The PRESIDENT: You are mentioning a Council in each of the three divisions of the kingdom. That idea has long ceased.

Dr. WATERS: It has long ceased. It there were a Council in each division of the kingdom, then the profession should be represented in such Medical Councils; but now there is only one General Medical

Council, and we hold that in that Council the profession ought to be represented, and therefore, so far as the enactments are concerned, although instead of Medical Councils there is happily but one General Medical Council, still we hold to that great principle. That is a mere matter of detail; but we hold to the principle that the medical profession ought to be represented in the General Medical Council. Now I do not know whether it is necessary for me to go into all the arguments in favour of this.

Sir JAMES PAGET: I think I may say, for every member of the Council, that we have read them all. I should be ashamed of myself if I had not read them carefully.

Dr. WATERS: Then I may assume that it will be admitted. But there is no doubt that the money paid as registration fees by the sixteen thousand or eighteen thousand members of the profession, when this Council was first formed, amounting to something like £36,000 or £40,000, constituted the bank upon which this General Medical Council commenced its general operations. From that day, there has been a registration fee exacted from every member entering the profession. We enter the profession, and are contented to pay it. Well, we feel that, if the working man be represented in Parliament, and if it be believed that the representation of the working man is a valuable addition to the legislature, surely educated members of the medical profession may safely be trusted with the election of representatives to the General Medical Council. I will not go through all these arguments; for, as Sir James Paget has said, they have been placed before the profession, and they will be continued to be placed before the public and the profession; but, as far as my experience goes, I do not meet with more than one or two persons who do not hold that the profession ought to be given direct representation in the Council. My object in submitting the Bill of the Association to the consideration of the Council was, that in its provisions were made for the direct representation of the profession; that the clauses were drawn and carefully considered; and that it is believed that, if those clauses be carried, then the work will be easy, and quite easy, and that there is really no difficulty in the matter; and it is with the view of drawing the attention of the General Medical Council to this question of medical representation on the General Medical Council that we wait upon you, sir, to-day. I would say the two points for which we are now contending are, first, representation of the profession in the General Medical Council, and next, the establishment of an uniform conjoint scheme of examination to be made compulsory for the kingdom.

Sir JAMES PAGET: Do you mean one for the whole kingdom, or one for each division of the kingdom?

Dr. WATERS: One for each division of the kingdom. It is a matter of detail.

The PRESIDENT: Are there any other members of the deputation who desire to offer any observations?

Dr. DAVEY: I would beg leave to say a word or two. I conceive that the propositions put forward by our Chairman are exceedingly important; and I could hardly consider it possible that any gentleman of the Council sitting around the table can do anything else than concur in the opinions expressed by Dr. Waters, as to the due representation of the profession at large in the General Medical Council. It is a matter which appears so sensible, and must certainly so impress itself on the mind of each gentleman I address, that surely no objection can possibly be taken to the matter. I look with confidence to the general support of every one present, not only of each individual member of the Medical Reform Committee, but of each gentleman holding office and representing the General Medical Council; for the one portal system in so far as applies to each division of the kingdom—that is to say, a portal in each division of the kingdom—is a matter that must recommend itself also to the conviction and opinion of every gentleman competent to exercise his judgment. At the present time, we know very well that various gentlemen enter the profession very easily, and probably it may be considered that very easy entrance into the profession results from the fact of there being so many licensing bodies. I believe the existence of such a number of licensing bodies tends very much to disparage the medical profession in the eyes of the public; and that the interests of the profession, and the well-being of the public also, will be very materially promoted by the one portal system; and furthermore promoted by the introduction of a fair representation of the body of the profession into the General Medical Council. Such are my opinions; and I do not think there is any gentleman in this room who is really opposed to the opinions expressed so far by Dr. Waters and myself.

Dr. WATERS: If I might be allowed one observation more, it is this. I believe the alternative has been submitted of what is called indirect representation; that is, that the members of every licensing body should have a voice in the election of the representative of that body in the

General Medical Council, and that that would be an improvement on our plan. After the greatest deliberation and consideration, we cannot come to that conclusion; we see no gain whatever that could be attained by it. If we take the profession in Scotland, it does not form a constituency as large as that which represents the University of Cambridge, where all the graduates have a vote in the election. Then, if we take England, where we have the College of Surgeons, we have, I believe, at least sixteen thousand members, and you have there an enormous constituency, at least as unmanageable as the whole profession of England. Then, again, many members of the profession are members of the Royal College of Surgeons and licentiates of the Apothecaries' Company, and graduates perhaps of some University; and I do not know that they are the better men because they have so many qualifications. It may be assumed that so many qualifications are taken with the view of impressing the public favourably; but they would either have to vote for the election of the representative of the several bodies to which they belong, or else they would have to make a selection. We think the simplest plan is that the profession should have its representatives, and that it should have the power of electing them; and, I believe, without that, the profession will not be satisfied. I may further say we have been issuing circulars lately, and we have had from all parts of the kingdom answers in favour of direct representation; and I do not see how it is possible for the General Medical Council to be at issue with the great body of the profession as to this matter.

Sir JAMES PAGET: I do not profess any opinion at all as to the question of direct representation, but I wish to ask a question with regard to the method of election. The election will be, of course, by proxy-papers to be sent to some central office. I do not know whether the Association would also recommend that it should be by ballot, that is, that the name of each ballot should be concealed at the same time that he voted by proxy. It would be necessary to be considered, because, so far as I know at present, that double manner of election does not exist anywhere. There is voting by proxy and voting by ballot; but I do not know whether, in any large matters, there are any instances in which ballot and proxy are both observed. I do not know whether the Reform Committee of the Association have considered that.

Dr. WATERS: The clauses which the Association has promoted are simply for election by voting-papers, and it seems to be a very simple means of accomplishing the desired end. The question of ballot never entered into our consideration.

Sir JAMES PAGET: Did it not? Is the name of the voter in every case to be given out as a person voting for this or that representative of the profession? That is a very important matter.

Dr. WATERS: So far, that is the arrangement proposed. It is not proposed that there should be ballot, but the question is not one of detail. The question is: Shall the principle be acknowledged that the profession, as a body distinct from the corporations, should be represented on the General Medical Council?

Dr. ANDREW WOOD: I would put it to Dr. Waters that, no doubt, it is a distinct principle; but, unless you can prove the details by which you are to carry out that principle, there is a difficulty in coming to a conclusion upon it. I am not giving an opinion upon it. I have my own opinion; but you said there are sixteen thousand electors in England. Now, do you propose that the sixteen thousand electors in England are to vote for the four, or are you to divide England into electoral districts? I would like you to direct your attention to that.

Dr. WATERS: That is a matter of detail. We go in for the principle. We have not thought, as far as we are concerned, of dividing England into electoral districts. We have done our best as far as our Bill is concerned, and we are sanguine that those principles for which we contend will triumph sooner or later. Two of the things for which the Association have contended have been granted; the third—the conjoint scheme—is on the point of being granted; and I believe the fourth will naturally follow, that is, a representative Council; but we do not imagine for an instant that any Bill can pass through Parliament without being more or less modified before it becomes law. The Duke of Richmond has brought the Bill into the House of Lords. I do not know whether he is sanguine as to its passing in its present shape, but it is certain that that Bill must meet with the strenuous opposition of the Association.

The PRESIDENT: I do not know whether you wish to go into the question, but can you say to what particulars in the Bill we are now all considering you object?

Dr. WATERS: We object to the permissive clauses and to the absence of representation.

Dr. ANDREW WOOD: Has Dr. Waters calculated what the expense would be of such a measure? I can tell him that, in order to obtain votes in the Universities in Scotland, at any rate, where there are, I think, two or three thousand electors, the expenses are so great

that it forms a very severe tax on the candidates—in fact, a man does not get in under two or three thousand pounds for these Universities. I observe in your Bill you state the expenses of the election are to be borne by the Council. Now, I just wish you to direct your attention to that—as to how those expenses are to be met, and whether you think such a tax upon the funds of the Council will not seriously interfere with their action?

Dr. WATERS: In the Bill it is very clearly stated that the Registrar in each division of the kingdom will have to issue circulars, and that he will receive those circulars, and that then the election will be decided by the votes in those circulars. For those expenses, the General Medical Council will be responsible, and they will be a trifle. They will be something like one canvass of the Medical Benevolent College at Epsom. We do not suppose, for instance, that we are going to have gentleman standing up for seats in this Council who have a political career before them, as almost all the members for the Universities have, to whom the expense of an election for Cambridge, Oxford, or Edinburgh is a mere trifle. They would not regard it. They are perfectly satisfied to get, at whatever cost, a seat in the Imperial Legislature. We think that the expenses would be very trifling.

Dr. QUAIN: I wish to ask Dr. Waters whether he could not have had, in Lord Ripon's Bill of 1870, the compulsory clauses for conjoint examination, in addition to uniformity of practice, if he and the authorities he represents had not interfered to prevent that Bill from passing? And I would ask also, if he had not been offered a Select Committee to go into the question of direct representation?

Dr. WATERS: I answered that question in the observations I have already made. I said we were at the time not a Medical Reform Committee. We were a Committee appointed by the Association at Dublin, and secondly at Oxford, where the numbers were greatly increased; then at Leeds; and we were a Committee formed with a specific purpose—that of obtaining direct representation of the profession in the General Medical Council. We represented that to the Government at the time, and we told them we liked their Bill as far as it went, only in that respect we would modify it as far as regards the power given to the Privy Council over the General Medical Council; for, if we had direct representatives in the General Medical Council, then it would be a body entitled to the absolute confidence, not only of the Universities and Corporations and of the Government, but also of the profession. We thought it would be a Council—I must be pardoned for saying it—not sitting on a narrow basis; but a Council representing not only the Universities, but the public. Well, we had no power to accept the proposal on the part of the Council. I consulted with those gentlemen acting with me, and we had our amendments drawn, and we presented our amendments to the Government, but the Government would not receive them.

Dr. QUAIN: You were offered a Committee of the House of Commons to go into the whole question.

Dr. WATERS: That is perfectly true; but you must remember that Governments rise and fall, and we could not say whether that Government would be in existence in the following session or no. Then I put myself in communication with persons to whom I had access, and I spoke to a gentleman now dead, Mr. Glyn, the brother-in-law of the then Premier, and he told me we had done perfectly right in not accepting that offer of the Government.

Dr. QUAIN: Then we distinctly understand that, owing to the action of the Reform Committee, Lord Ripon's Bill was stopped; and I would ask, from that time to this, what has the Reform Committee done to advance the question?

Dr. WATERS: We have done our best.

The PRESIDENT: Dr. Quain has put a question to you, whether the Bill would have passed had it not been for the action of the Reform Committee.

Dr. WATERS: That I cannot say.

Dr. QUAIN: You take the credit for it.

Dr. WATERS: I cannot say.

Sir JAMES PAGET: I beg for myself to say that it should not be assumed that I or the whole body of the General Medical Council offer any decided opposition to direct representation. So far as I know, for many years past no opinion has been expressed on the matter; it has never been discussed since I have been a member of the Council. Now, the present Bill seems to be a piece of legislation not necessarily associated with the matter. It seems entirely open for the Medical Council to consider it fairly and dispassionately; only I may be allowed to say, when you talk of principles and details and all those matters, you are apt to suppose they are entirely distinct things. Now, many principles are made up of details, and every detail involves a great principle; therefore, whatever opinion you have to express in the matter as an expression of the profession to the General Medical Council, I should have to con-

sider whether the thing can possibly be worked—whether the details will not render the principle altogether impracticable. I do not say for a moment it is so, but, in regard to that one point about which I asked, it is very singular that a body interested in the matter could not have decided what would be the method of voting, because in the House of Commons that would be a direct question. Are we to have a system of voting combining the systems of ballot and proxy—that is to say, which reduce the responsibility of each individual voter to the lowest possible level? I do not say whether it is right or wrong, but that is a great principle in itself—the diminution of the responsibility of each separate voter by enabling him to vote secretly and by proxy. Proxy is excellent, and ballot is excellent; but, so far as I know, there is no instance in this kingdom where both are adopted. That is the principle to be decided by the Medical Council.

Mr. MACNAMARA: Is it not proposed to be by ballot?

Sir JAMES PAGET: By proxy.

Mr. MACNAMARA: But, would not proxy go directly against the ballot principle adopted by the House of Commons in its present state?

Dr. ANDREW WOOD: The Universities vote by proxy and not by ballot.

Dr. WATERS: Sir James Paget has directed a question to me. The answer is this: that the profession has gone in for voting by proxy, excluding ballot.

Sir JAMES PAGET: Excluding ballot.

Dr. WATERS: It is voting by proxy; but our object is to have everything fair and aboveboard.

Sir JAMES PAGET: Open vote?

Dr. WATERS: Open vote. That is the desire of the profession.

The PRESIDENT: I will make one observation on Sir James Paget's speech, and on one or two expressions that have fallen from Dr. Waters. Allow me to say this; and I will illustrate it by a letter which came to the office since the Council met, in which two distinct questions were put, which I had to answer. One is, what the Medical Council had ever done for the profession? and the other is, which member of the Council represented the profession? Well, I declined to give any answer to that in private; but I did give an answer in the Hall of the Apothecaries' Society—and the answer is a very simple one—that the Medical Council, appointed under an Act of Parliament to discharge special duties, has been doing its best for the profession. Whether it could have done better, is another question; but it has done its best; as an old member I may be allowed to say that, and I cannot allow, on behalf of the Council, any assumption that it has done otherwise. It is administering an Act of Parliament; and every gentleman on the Council is appointed to discharge that duty as well as he can. And then the second question, about which I think there is often a misunderstanding, is the supposition that there is no member of this Board that represents the profession. My answer in public before the Apothecaries' Society was this: "I should like the member of the Council to be named who would dare to rise in his place, and admit that he represents anything else but the profession, except it be the nation at large." It is often assumed that at this Council Board the sole motive is the representation of a particular body. I think that those who sit around this table, and during twenty years have seriously endeavoured to discharge the responsibilities put upon them, ought not to admit that; because, if they did, they would admit what was not really the case. We cannot receive any statements or representations admitting as a body that we desire less than any other of our brethren in the profession to discharge our duties, or that the whole motive power of this Council is for particular institutions and not for the country at large. I trust the Council will say I am right in saying this. With regard to the particular point Dr. Waters has brought before us to-day, I would only observe that we are called by the Government to give an opinion upon a certain number of clauses, and we are doing our best to do so. What is before the Council after two o'clock is the consideration of this document; and if this document or any other document come before us, it will be attended to with the same attention and sincerity.

Dr. QUAIN: There is nothing more important than the uniformity of examination; and I want to place the blame of not having that on some one, and that is on those parties who contrived to get Lord Ripon's Bill thrown out. That is distinct; and I do not think Dr. Waters will deny that the persons whom he represents were those who threw out that important Bill. I want simply to know what has been done since that time towards advancing any of the questions to which Dr. Waters has referred. Now, we are met again with the hope of getting another Bill, and very likely with the same result. I say, therefore, it is very much to be lamented if, for these past eight years, no actual step has been taken to promote this object. I know no step, except that a report was brought

before the meeting at Manchester, and that, by a majority so large and so decided that it led Dr. Waters and other members of that Committee to retire, the meeting on that occasion voted for, not this direct representation, but that the profession should be put on a proper footing with regard to quacks and quackery. When those gentlemen retired, the Association was content. It did not ask them to come back; but they very properly met and re-appointed themselves. I do not know that they did wrong; but they are not the voice of the British Medical Association, except indirectly. Well, since that meeting at Manchester, the voice of the Association has not been expressed. I believe the proceedings of the Association at Newcastle led to the retirement of some of its most distinguished members; but they have rejoined it in the hope that in future this important question should receive the support of the Association. I want it to be distinctly understood that the British Medical Association caused the rejection of the Marquis of Ripon's Bill. A Special Committee was offered, and one Government is bound by the acts of another.

Sir DOMINIC CORRIGAN: No, no.

Dr. QUAIN: Sir Dominic Corrigan's experience of the House of Commons has been greater than mine; but, if one Government offered a Select Committee to a public body to inquire into a public question, a following Government would never refuse it.

Mr. MACNAMARA: I would say a few words to Dr. Waters, and I am quite sure he will accept them in the spirit in which they are offered; and that is, that this Council, subject to the correction of the President, has been principally called together this session to consider the Lord President's Bill; and, as you have already stated, there is not one word as to direct representation in that Bill, nor has the Lord President asked us our opinion on that subject. As far as I understand, the session is coming to a close to-day. There is a great deal of very important matter still before us, to which the Lord President has directed our attention, and in reply to which he expects an answer. Now, if Dr. Waters could get the Lord President to direct our attention to direct representation clauses, there is no doubt that this Council should devote itself to it; but, unless it is brought in that substantial way before this Council, I think it is only my duty to tell Dr. Waters and the deputation present, that I cannot see how an answer can be given on the subject of direct representation at the present sitting of the Medical Council.

Dr. ROLLESTON: I would ask Dr. Waters upon what basis is this direct representation asked for? Now, there are two views, upon either of which a person has claimed, and may claim, to be represented. The first view is that of the University of London, that, by being represented upon a particular body, whether in the House of Commons or elsewhere, that body will be improved and made better and more efficient. That is one theory; that is Mr. Robert Lowe's view. Now, the other view is this: that whether persons by being added improve the deliberative body or not, if they have the right to be represented, it should be given to them. That is a totally different view from Mr. Robert Lowe's view. I think I have made myself plain. I have no doubt Dr. Waters will have made up his mind as to which of those two views for asking for a vote the British Medical Association thinks the more admirable. I should be glad to know, if he represents the profession as well as he represents the Association, upon which of those two views he will base his claim.

Mr. TEALE: I should like to ask Dr. Waters what the view of the Committee is on these two points, because it is when you come to details that you find difficulties in matters of this kind. Is it the opinion of the Committee that the present Medical Council should be added to, or that the members selected directly by the profession should displace an equal number of the Medical Council; and, if so, how is it to be decided which of the members of the Council go out?

Sir D. CORRIGAN: I think there is the *prima facie* objection to the manner in which the present proceedings are conducted, that the questions all come from this side. That means that we are to conduct a cross-examination of the Committee waiting upon us, but there is no provision for their asking any questions at all. I do not think that is fair. I think if one side has a right to ask questions, the other side should have an equal right to do so.

Dr. WATERS: Perhaps, it would be convenient that I should answer the questions put, because they are all fresh in our minds, and I am sure there are other members of the Committee—at least, I sincerely trust there are—who will not refrain from the expression of their views on the matter, because of my having so frequently spoken. I should like to make a few observations with regard to what has fallen from Dr. Quain. He is very anxious to fix upon me—I do not know how I am so very important a person—the rejection of the Marquis of Ripon's measure. Well, I may say that I had very able coadjutors on that occasion.

Dr. QUAIN : I said you represented them.

Dr. WATERS : I may say I had very able coadjutors upon that occasion, and I consulted several distinguished members of this General Medical Council. When the notice of the second reading of the Bill was put down on the paper in the House of Commons, I received a letter from Mr. Macnamara—I hope I am not guilty of any breach of confidence in stating it—begging my immediate presence in London to oppose the Bill (I have his letter here), and I came up immediately. I travelled up with the late Dr. Hughes Bennett, who was a member of our committee at that time; and very busy we were in the House of Commons. Mr. Macnamara was one of the most active opponents of the Bill. He induced his College on that occasion—or, at any rate, his College actually did so—to petition in favour of direct representation. The College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, did the same. I am speaking to the best of my belief. I do not know whether their object simply was to throw out the Bill; but, at any rate, such was their action, and I did not stand alone in opposition to the Bill. As to my own personal feelings, that is quite another matter. I felt I was bound to oppose the Bill. I was not acting for myself; I was acting for the Association with a distinct mission. Now, as regards Dr. Quain's glowing description of that meeting at Manchester where this resolution was passed, which, he says, represented the voice of the Association, the fact is that, at the far-end of the meeting at Manchester, when there were not thirty-five persons present, an abstract resolution took the meeting by surprise. Now, we hold that a resolution passed without notice, and by such small numbers, cannot be taken as representing the voice of the British Medical Association. It certainly did not represent the voice of the Medical Reform Committee. Now, as regards Dr. Rolleston, he puts two questions to me: either I am to lay the claim for direct representation on the basis which Mr. Lowe assigns as a good ground for obtaining it, or else I am to look for it as a right; and Dr. Rolleston says that I must accept one of these two views. I demur to that. I say the thing may be a right, and that the concession of the right by the introduction of members of the profession into this General Medical Council may not do the Council any harm. In my opinion, it will introduce into it an element which it does not now possess. I believe that the members around this board are not so acquainted with the needs and wants of the general practitioners of this country as is desirable for the good of the community.

Dr. ROLLESTON : Just specify those needs; that is what I want.

Dr. WATERS : On that account, I say the introduction of this element will benefit the General Medical Council. I think also it is a right, because the body that finds the funds by which this Medical Council is enabled to meet at an expense of £400 a day, as the President told us in his address.

The PRESIDENT : Not £400 a day, but £400 if summoned for one day.

Dr. WATERS : Well, I say the body that finds that £400 which is spent in discussing the rival merits of various corporations, whether, for instance, bodies shall be merged or not, so as to form conjoint boards for examination, has a right to be represented. Therefore, when Dr. Rolleston wishes me to select one view, I select both as entitling us to direct representation on the Medical Council. I am free to admit that the time spent here to-day has been spent agreeably and, I believe, with profit, notwithstanding the unfavourable aspect of affairs at the commencement. Dr. Quain knows I have only one object to serve and no other. I do not wish to show any disrespect to the Council; I am here simply to-day out of deference to the Council, and because I believe that the Council should move in this matter; that, as the Council is at the head of the profession in this country, it ought to be made acquainted with the desire of the profession; and that it should have, therefore, the opportunity afforded it of taking it into consideration. I hesitated about the step, because I did not want to trouble the Council too frequently; but we have allowed several years to elapse without troubling the Council. It was years ago that we appeared before them, and we come before you to-day to ask you to consider this prayer of the profession. I am very glad to have been cross-examined to-day, if by my answers I can more clearly show what the Association wishes. As regards Mr. Teale's question, that is also a matter of detail. I believe it would be impossible to carry a Bill through the House which would not meet with a great deal of opposition as to representation. The view of the Association is, that it would be better not to increase the number of members of the General Medical Council; that, as Edinburgh and Aberdeen are linked together, and only have one representative, there is no reason—I hope I shall not be deemed offensive—why the Apothecaries' Society of Dublin should have a representative to itself. I do not see why a single college should not have a representative in a city where the university of that

city—one of the most important colleges in the world as regards medical education—has a single representative. I think some of these colleges might be represented; but it is not for us to court opposition; we have had enough of it to contend with; and therefore we go in for the principle of bringing in our amendments and proposing them. If members of the House of Commons or the House of Lords should think it desirable to link bodies in representation, all well and good; we make no objection to that; all we desire is that we should have one-fourth of the Council, and the Government one-fourth of the Council; and that the universities and professions should form one-half of the Council; and we think that by this the Council would be improved. That is the deliberate opinion we have come to. We do not say we are to disfranchise this or that body. Why should we? But, if it be desirable to embody bodies in representation in the same way as Edinburgh has been linked with Aberdeen, well and good.

Dr. ANDREW WOOD : Has the Association laid those views before the Duke of Richmond?

Dr. WATERS : Yes; but he said nothing about the subject.

Dr. QUAIN : Dr. Waters has made use of a very remarkable phrase—"taxation". Now, I am not disposed to think that the fee for registration can in any sense be called taxation. A very great privilege is given for the fee paid for registration. How very different is the solicitor's annual licence! A very considerable sum; I do not know how much it is; and what representation has the solicitor for the fee he pays? It is simply a licence to practise; and a gentleman comes here, and, under the law, he cannot practise without paying a fee of five guineas. I do not think that can be called taxation. It is a fee paid for the privilege given by the legislature for the right to practise everywhere; and each of us is represented by the member in Parliament, who imposed this fee. If I have spoken so frequently now, it is because I have often talked over this subject with my friend Dr. Waters; and probably I know as much about the whole question as many do. Why I was a little annoyed in the first instance was, that the Council should be blamed for not receiving this deputation at a particular hour, when I knew that the deputation was engaged at a meeting of its own body at two o'clock.

Dr. WATERS : I most distinctly disclaim it. I said so once before, and now I rise again and say, I am here out of deference to the General Medical Council.

Dr. QUAIN : If that be the case, and Dr. Waters did not, as I understood he did, find fault with the Council for not receiving him, I am exceedingly sorry I made some of the observations I felt it my duty to make; but I was under the distinct impression that Dr. Waters said the Council would not receive him.

Dr. STORRAR : I am exceedingly desirous to be perfectly clear as to the present relations between this deputation and ourselves. With regard either to the matter or the manner of Dr. Waters, I am sure I can have nothing to criticise. His intelligence and graciousness of manner under very trying circumstances really command my thorough respect. At the same time, I think that, in so important an interview as this, it is necessary that we should be quite clear as to our mutual relations. Now, as I understand, the gentlemen here before us are not the Committee of the British Medical Association, but they are members of that committee only, and the committee, as a committee, decline to come here.

Dr. WATERS : I wish to explain the absence of a few members of the Committee. I have found myself supported almost beyond my expectations, considering the shortness of the summons and the distance those gentlemen have had to travel. I was agreeably surprised when I found myself accompanied as I have been to-day. The other members of the Committee are not here, simply through a misunderstanding. It was supposed that it was rather an invitation to me personally than to the Committee; but I think that matter has been put right.

Dr. STORRAR : I confess I understood from Dr. Waters that there were certain gentlemen belonging to this Committee who declined to be present at this meeting, in consequence of the objection they raised to the manner in which they were to be received. The consequence is, we can hardly look upon the gentlemen before us as representing the whole Committee. Another remark I have to make is this. I desire emphatically to say that I express no opinion as to the views that have been expressed upon the subject of direct representation. I would wish to look upon this as an open question to be very dispassionately considered; but what I want to know is, how far Dr. Waters is technically accurate in representing the opinions of the British Medical Association upon this point. He acknowledges that it was mainly due to the efforts of the British Medical Association that Lord Ripon's Bill was defeated. Now, it does not appear to me that any very strenuous efforts have been made by the British Medical Association from the

time of the rejection of Lord Ripon's Bill up to the present time to promote these views of direct representation; and it seems to me that there is a missing link in what we hear as regards the meeting in Manchester last year. It seems that this question of direct representation dropped out altogether. The link was broken for the time. I am accustomed, in the University of London, to deal with the great difficulty of meetings falling away towards the end; but, whether they fall away towards the end or not, the bodies are equally bound by the votes of that meeting; and the simple fact is that the question of direct representation dropped and merged in the question of strengthening the penal clauses of the Medical Act, as I understand. I know nothing but what I have heard in this room. If it did not mean that, why did Dr. Waters retire from the Committee? Dr. Waters seems to have been so much impressed with what happened at the meeting, that he withdrew from the Committee altogether, and then, under influences which one can quite understand, highly honourable to the Committee and highly honourable to Dr. Waters, he was induced to resume his place on the Committee. At the same time, I cannot help feeling that in the unity of this history there is a link missing, and we have a difficulty in actually seeing the British Medical Association before us in regard to this question. I say this, because I think it is necessary to the proper understanding of our position. I do not enter into the question of direct representation. There is a very great deal to be said in its favour, and I hope it will not be understood that I am saying one word at the present moment hostile to the principle; but I felt that this conference would not be complete without our understanding what our mutual relations were, and what was the defect, if defect there be.

Dr. WATERS: I shall be very happy to explain. At the meeting at Manchester, the report of the Medical Reform Committee was brought forward and carried. Then came a resolution, and that resolution was that, considering the difficulties attending legislation on private matters—and we are all acquainted with those difficulties—it would be better not to go in for the broad features of medical reform, but that the Committee should be instructed to frame a small Bill, in the absence of the ability to carry the greater measure, which would secure the general practitioner from the loss he sustained through irregular practitioners. I had a special objection to committing myself to go in for a Bill of that character; and this Council, knowing how difficult it is to carry any private measure through Parliament without the direct sanction of the head of the Government, will easily understand that I did not go in for that one private Bill. I would not disregard the interests of the general practitioner. I think, in his hard work, he well deserves the protection the law can throw over him; but I would not have to do with a Bill expressing that one feature only. On that ground, I retired from the Medical Reform Committee. The remaining members of the Medical Reform Committee met in London, and I was invited to attend. I thought it right and proper to attend, and the representations then made to me induced me to resume my seat at the Medical Reform Committee. In that position, I was authorised to communicate with various members of Parliament with whom I had previously been in communication, and I loyally submitted to those gentlemen—some of the most influential in the House—the measure proposed by the resolution at Manchester, and the reply I met with was that it would be fatal to the influence of the Association if we went in for that one point alone. Now, as regards the absent members of the Committee, I may say we met at Dr. Stewart's house; indeed, to his hospitality we are indebted for spending a delightful evening together, and those gentlemen who are absent stated that it was unnecessary for them to be present, because they entrusted the expression of their views entirely to me. I should not wish to repeat this, but I think it is essential in reply to Dr. Storrar. We are entirely agreed; we have no point of difference; and they knew, though their absence would diminish our numbers, it was safe to entrust the expression of their opinions to me. It is in that way I am here, with the other members, as representing the Medical Reform Committee.

Dr. PYLE: I should like to ask Dr. Waters whether the feeling of the profession is not more in favour of having a Bill that would deal with the penal clauses and give them protection, than of direct representation on the Council.

Dr. WATERS: I cannot say I think so, because I do not think so. When the meeting was almost broken up at Manchester, a resolution was suddenly brought forward and carried. There had been seven hundred or eight hundred members present; but the resolution was passed at the end of the meeting, and cannot be said to represent the opinion of the British Medical Association.

Sir D. CORRIGAN: I have very few remarks to make. I think the great question before us to-day has been the direct representation of the profession on the General Medical Council. I think we have

shunted that question. Every speaker who has risen has declared that he would not give an opinion upon it. Now I will give an opinion upon it; and I must say that I do not think that the Council, as at present constituted, does represent the profession. As every one is entitled to give his opinion, I will give mine. I do not think this Council represents the profession of the United Empire. It represents corporations; it represents universities in which the profession plays a very small part and has very little influence indeed. I will not go beyond the university which I myself represent—the Queen's University in Ireland—and I say that I do not represent the profession. I am the representative of the Queen's University, and I am expected to advocate the interests of that university, but that is not the profession. How is the representative elected? He is elected by men who may happen to be medical men; that is a matter of chance. There is no positive connection between them and the work of the profession throughout the country, and when once a graduate gets a degree he is left to shift for himself, to exercise any little influence he has or not, but he has no voice in the management of this Council as to the wants or needs of the profession. I must, therefore, repeat what I said, that I think this Council requires to be amended by the introduction of direct representatives of the profession. I do not see any difficulty in it. I think a professor of an university is very much like a man in the middle of this table, or in the middle of a circus; he sees the university and the walls around it, but he sees little or nothing outside. Universities are very little better than the monasteries of old days; and I recollect, when I was President of the King and Queen's College of Physicians, and was engaged in the reform of the profession in Ireland some years ago, the appeal that was made to me was, "Oh, Mr. President, whatever you do, remember this; take care of the poor professors". That was the first object. The next was to look at the interests of the profession at large. I shall sit down, merely stating that I am an advocate for the direct representation of the profession; in what proportion I do not know, or how the particular details are to be managed; but I think it is not a question which the Council ought to shunt.

Dr. STORR: I must apologise for one word more. I should not have said it but for what Sir D. Corrigan has just said. I entirely dissent from some of the views which he has expressed. I represent an university, and I wish to make it distinctly understood by the gentlemen present what the position of an university representative is. It was not provided by the Act that he should be a member of the profession. If you look to section seven of the Medical Act, you will there see these words: "Members of the General Medical Council representing the medical corporations must be qualified to be registered under this Act". Now I happen to be a medical graduate and to be registered under this Act, but it would have been competent under this Act for the University of London to have sent a lay man to represent the University. This was done for an intelligent object. The view that was taken by the framers of this Act was that not only was the profession to be represented, but that the intelligent public should be represented; and I am here as the representative not only of the University, but of the public.

Dr. STEWART: I was one of those who resigned after the Manchester meeting; but, as it happens, my resignation was never accepted. I have received my summonses ever since, and have been looked upon as a member of the Committee. It is very important that the Council should understand why nothing has been done during the last eight years. Some of the most influential members of the Medical Reform Committee—among them our late much-loved friend Dr. Sibson—begged that the Committee might take no steps lest they should interfere with the success of the projected conjoint scheme of examination for England. Simply and solely in deference to them we have refrained from doing anything since then. We have, in fact, postponed our claim, which we consider a very strong one, for direct representation, in order that the efforts of the different corporations and universities in England might have fair play without any interference, in order to carry out the conjoint scheme.

The PRESIDENT: If no gentleman desire to make any further remarks, I beg, first of all, on behalf of the Council, to thank the deputation for coming here to express their views. I must recall your attention to the nature of this interview. The members of the Council, in obedience to the request of Dr. Waters of Chester, have met in the only way which he allowed as possible; namely, before twelve o'clock this day; and we have met, under those circumstances, in large numbers. We have met to receive the expression of your opinion, in order that we may deliberate upon it (not in the Council, for we are not now in the Council), and take such further steps as we can. I think I gather, as a matter of fact, that the chief object of the whole of the statements and arguments to which we have listened has been to let the

Council know what those whom you represent, whether this committee or that committee, or the British Medical Association, think of the constitution of the Medical Council. That Council is constituted in a particular way under the Act; it can act in no way except under that Act of Parliament, and can consist of no other persons than those whom the Act provides. They are discharging the only duty which they can discharge, and they are constituted in the only way in which they can be constituted. You, gentlemen, think the Council should be constituted in some other way, and that way seems to be this: that one-fourth of the Council should consist of persons elected by the medical profession, one-fourth be appointed by the Government—Crown nominees, and one-half be elected by the universities and corporations. That is your proposal, and I would venture to ask one question: Whether those whom you represent consider that the numbers of the Council, as a whole, are the numbers which you desire; whether, in the event of the entire reconstruction of the Council—and this is a most important question—it still should consist of twenty-four, or whether the numbers should be enlarged or diminished. That is the only question I venture to ask.

Dr. WATERS: We are satisfied either with the same number or with an increased number, or indeed with a diminished number; but we hope that that proportion which I have submitted to you will be preserved.

The PRESIDENT: Then the actual numbers of the Council are, in the opinion of those whom you represent, of no consequence one way or the other.

Dr. WATERS: We do not lay stress upon them. We do not say they are of no consequence.

The PRESIDENT: I need hardly remind either the members of the Council, or the members of the whole medical profession, of the principle upon which this Council was originally constructed. It is very important, in mere justice to the medical profession and to the public, and to ourselves, to bear in mind that the number of the present Medical Council was unavoidable, according to Mr. Walpole's and Mr. Cowper-Temple's view that every one of the corporations and universities should be represented, *plus* six Crown nominees. But you do not desire that number to be enlarged, and you do not ask it to be diminished; but the point is the proportion. I only wish, in conclusion, that we should bear this in mind—and I address this rather to the gentlemen who have favoured the Council with their presence to-day—that the Council are all keenly alive to the extreme importance of the duties which they have to discharge and endeavour to discharge; and that nothing would please them more than to learn how to do their work better, and for this obvious reason, that they have the work to do. If the Council can be in any way made a body to do its work better, surely all the members would desire it; and the only question is how. I am not authorised to make any remark at all. I cannot speak on behalf of the Council in any sense; but I must refer to one thing: that we are met this session to consider a particular Bill; that this is the seventh day of our sitting; and that I am not at present in a position to say whether it will be possible or not for us to go into the question of direct representation this session. I wish it to be understood that, if this matter cannot be discussed at the Council, it will be from no feeling of disrespect for the gentlemen present, or for the British Medical Association, nor from indifference to the subject, or want of conviction of its importance. We are met to consider this Bill, and whether or no this subject can come forward for deliberation by this Council I really cannot say. I think I may take upon myself to thank Dr. Waters and his colleagues for so frankly and fully laying this subject before us.

Dr. WATERS: I should like, on behalf of the deputation, to express our thanks to the President and the Council for the kind consideration they have given us at this meeting. I should have liked very much to have parted from them with a question as to what answer I am to give the absent members of my committee, just as I was asked what answer the Duke of Richmond gave to me; but I will forbear to put that question.

The deputation then withdrew.

### THE MEDICAL ACT AMENDMENT BILL.

THE following circular has been issued by the Medical Reform Committee:

Queen's Hotel, Birmingham, April 2nd, 1878.

Dear Sir,—A crisis, as you are aware, has arrived in regard to medical reform, and the action of the British Medical Association and of the profession is imperatively required to frustrate the passing of a

Medical Bill which does not embody the principles for which the Association and the profession have for so many years contended.

Under these circumstances, we urge upon you the importance of petitioning the House of Lords to prevent the passing of this or any Bill which does not recognise these great principles.

With that view, we forward a form of petition for your guidance.

Unless the petition be written on one side only of a sheet of paper it will not be received.

The petition may be forwarded for presentation to any local peer; to the General Secretary of the Association; or to Dr. Waters, Chester.

EASON WILKINSON, M.D., F.R.C.P., President of the Association.

RANDLE WILBRAHAM FALCONER, M.D., LL.D., etc., President-Elect and President of the Council.

CHARLES CHADWICK, M.D., F.R.C.P., Ex-President of the Association.

ALFRED BAKER, F.R.C.S., Ex-President of the Association.

MARTIN DE BARTOLOME, M.D., F.R.C.P., Ex-President of the Association.

W. F. WADE, M.D., F.R.C.P., Physician to the Birmingham General Hospital, etc.

BALTHAZAR FOSTER, M.D., F.R.C.P., Physician to the General Hospital, Birmingham.

ALFRED CARPENTER, M.D., Lecturer on State Medicine, St. Thomas's Hospital.

EDWARD WATERS, M.D., F.R.C.P.E., Chester, Chairman and Convener of the Medical Reform Committee, and Ex-President of the Association.

#### Form of Petition.\*

The following form of petition was suggested. It must be written and not printed.

Unto the Right Honourable the Lords Spiritual and Temporal of the United Kingdom of Great Britain and Ireland, in Parliament assembled.

The humble petition of the undersigned, registered medical practitioners, residing in \_\_\_\_\_ and its neighbourhood, sheweth—

That the Medical Profession, as distinct from the Universities and Corporations, has for nearly fifty years contended for medical reform, and contributed greatly to the passing of the Medical Act of 1858.

That a Bill, intitled an Act to Amend the Medical Act, 1853, has been brought into your Right Honourable House.

That, in that Bill, no provision is made for the introduction of direct representatives of the profession in the General Medical Council.

That the Bill does not provide compulsory enactments for the establishment of a conjoint board for the examination of medical candidates in each division of the kingdom, on the principle of equal fees and equal examinations; and that such enactments are indispensable, in the interests of the public, to abolish the competition downwards in the granting of medical licenses and diplomas.

Your petitioners pray your Right Honourable House not to pass that, or any other Bill, unless provision be therein made for direct representation of the profession in the General Medical Council, and for the compulsory establishment of conjoint boards of examination, on the principle of equal fees and equal examinations in each division of the kingdom.

And your petitioners will ever pray, etc.

An attempt has been made by the Medical Reform Committee to forward the above letter and form of petition, though without complete success, to every member of the profession in the United Kingdom, together with a circular asking for the plain answer "Yes" or "No" to each of two questions.

1. Are you of opinion that the medical profession should be directly represented in the General Medical Council?

2. Are you of opinion that the establishment of a conjoint board for the granting of licences to practise all branches of the profession should be made compulsory in each of the three divisions of the kingdom?

The members of the Committee whose names are attached to the above letter were unanimous as to the importance of this canvass of the medical profession, and urge the members of the Association to send in their answers and to use their influence with those who are not members to do likewise.

Petitions should be written on one side of an open sheet of foolscap

\* Instructions for the Proper Preparation and Execution of Petitions.—Every member of Parliament presenting a petition to the House must affix his name at the beginning thereof. Every petition must be written, and not printed or lithographed. Every petition must contain a prayer. Every petition must be signed by at least one person on the skin or sheet on which the petition is written. No letters, affidavits, or other documents, may be attached to any petition. No erasures or interlineations may be made in any petition. No reference may be made to any debate in Parliament.

and signed at the foot of the petition on the same side of the same sheet by at least one person. Any further number of names may be subsequently added by joining additional sheets. The petitioners should append their qualifications and appointments.

### HARVEY TERCENTENARY MEMORIAL FUND.

THE amount subscribed to the Harvey Memorial Fund now exceeds £1,400. We last week noticed the circumstance that the Fellows of the Royal College of Physicians of London had subscribed £105; we to-day hail with equal satisfaction the fact that the Council of the Royal College of Surgeons of England on Thursday last contributed £105 to the fund. The Executive Committee cannot, however, as yet desist from their endeavours to add to the fund, but they are desirous of closing it at as early a date as possible. We are asked again to request the members of the profession who have not hitherto contributed to this object to kindly send their donations at once to either of the hon. treasurers (Sir George Burrows, Bart., or Mr. Prescott Hewett), or to either of the hon. secretaries (Mr. Geo. Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone), or to pay them into the account of the Harvey Tercentenary Memorial Fund at the Western Branch of the Bank of England, Burlington Gardens, London, W. Subscriptions from five shillings upwards will be very acceptable.

## SPECIAL CORRESPONDENCE.

### PARIS.

[FROM OUR OWN CORRESPONDENT.]

*Dr. Reliquet's Work on the Urinary Organs.—Alterations in the School of Medicine.—Teaching of the Deaf and Dumb.—Digitalis.—Society of Professional Ladies.—Death of M. Roubaud.*

ABOUT ten years ago, Dr. Reliquet published a treatise on the surgery of the urinary organs, which met with great favour with the medical public. He is now putting together the lectures he has since delivered at the École Pratique. They are being published in parts. The first part of the work, entitled *Lectures on Diseases of the Urinary Passages*, has just appeared. In his first lecture, the author treats of micturition, which function he divides into three stages or acts. The first stage consists in the filling of the bladder with urine, which he terms the normal retention of urine. The second stage begins with the sensation of the necessity for urinating; and the third completes the act by emptying the bladder. The mechanism of these different stages is fully explained; and the author follows this by considerations of the function of micturition in children and in women. Most medical men must have remarked that women retain their urine much longer than men, and I have known some women who could do so for twelve hours without inconvenience. This power of resistance is explained by Dr. Reliquet to be due to the peculiar structure of the female urethra, which is entirely surrounded by muscular fibre, from the neck of the bladder to the meatus, which latter is the only part of the canal devoid of muscular fibre; and this constitutes the great difference in the structure of the male and female urethra. But, while the power of retaining the urine is so marked in women in the normal condition, the slightest pathological cause is often sufficient to excite a frequent desire in them to micturate. This morbid tendency sometimes extends to incontinence, and even the act of laughing is sufficient to cause in women an involuntary emission of urine—a circumstance rarely or never met with in men in any condition. Dr. Reliquet next treats of the influence of the will on the act of micturition, the state of antagonism or opposition that exists between the bladder and the urethra, and the innervation of the urinary bladder. In the following lecture, the author considers the various causes that may prevent the normal emission of urine, which he groups under the head of Spasms of the Bladder and of the Urethra. Here, I must confess, I cannot follow the author, as he places under the term spasm, as the proximate cause of obstruction, the various morbid conditions that play a part in the etiology of the retention of urine. The greater portion, he states, of patients labouring under affections of the urinary passages present, in a more or less marked degree, phenomena of a spasmodic character, superadded to the lesion already existing, which derange the function of micturition. This is, so far, sufficiently intelligible; but when he asserts that spasm is the immediate cause in every case of retention of urine, even when there is some organic lesion present, either in the neck of the bladder or in the

urethra, I do not think he will find many surgeons agree with him. The *brochure* under notice concludes by some remarks on the action of chloroform on the urethra and bladder. The author states that the complete action of this substance on the sensibility of the urethra stops at the neck of the bladder, when the latter is the seat of local irritation; in the female, the action of the anæsthetic on the urethra is complete. As for the bladder, the inhalations, far from diminishing its sensibility, appear, on the contrary, to increase it, when it is the seat of some lesion; but, when healthy, the bladder dilates under its influence.

The School of Medicine is undergoing complete transformation. It is to be considerably enlarged, to about three times its present size, and it is to have a new front, monumental of its kind, facing the Boulevard Saint-Germain, also recently opened. The houses around the old building have all been pulled down, so that it will be completely isolated. The École Pratique also is to be considerably enlarged and improved. The cost is estimated at 4,000,000 *francs* (£160,000), and the buildings are to be completed in three years.

One of the most interesting proceedings one can witness in social life is the education of the deaf and dumb. For some time, the language by signs was the system in vogue in France; but, of late years, this is being replaced by what is termed the "visible speech method", not that which is known as the German method, but that introduced into France about the end of the last century by Rodrigue Pereire, one of the ancestors of the great bankers of that name. It consists of educating the pupils to imitate the various movements of the lips, throat, tongue, and teeth which are produced in speaking; and in order to give the subject an idea of the sound accompanying each letter or word, his hand is first placed on the tutor's throat while the latter is in the act of articulating aloud, and then on his own, which he is taught to imitate. He thus feels the sounds, as it were, and pronounces words which he cannot hear himself. This method is utilised even for the education of young children who are gifted with speech.

A very interesting discussion lately took place, at a meeting of the Société de Thérapeutique, on the therapeutic influence and mode of administration of digitalis in disease. Most of the speakers gave the preference to a cold infusion of the leaves over any other preparation, and were almost unanimous in condemning digitalin as being dangerous and unreliable, as it does not possess the diuretic properties contained in the leaves. Dr. Héraud, who brought the subject to notice, recommends the following preparation: Macerate, for twelve hours, twenty-five *centigrammes* of the powdered leaves of digitalis in two hundred *grammes* of cold water. This is then strained, and the patient is directed to take it in five or six doses, in the twenty-four hours, at some distance from meals. This dose, he said, should never be exceeded, if we wish to avoid its poisonous effects; and the quantity he prescribes is quite sufficient to produce the full therapeutic action of the drug, beyond which it is needless to push it. Dr. Héraud considers digitalis one of the best diuretics known in affections of the heart; whereas it is useless where there is no cardiac lesion, as, for instance, in cirrhosis, albuminuria, etc.

A certain number of ladies in Paris, of different nationalities, are endeavouring to get up a society for the benefit of their own sex, the object of which, as the prospectus declares, is to facilitate the study of medicine and of other arts among themselves, and at the same time to render their relations with one another more intimate and useful than at present obtains among them. The Society, which is designated "Société des Femmes Professionnelles", is to meet once a month, and is to be composed of a committee of seven members: president, vice-president, treasurer, secretary, and three other members, chosen by the society. Ladies registered as students of a college or university, those destined for literary instruction or the arts, or those belonging to any of the liberal professions, are eligible as members.

I regret to have to announce the death of Dr. Felix Roubaud, who, with M. Simmonet, whose death was noticed in the JOURNAL about two months ago, founded the *France Médicale*, one of the leading medical journals of Paris. Dr. Roubaud was born in 1820, and took his degree in 1844, when he selected for his inaugural thesis "The Passions". He was of a very active turn of mind, and looked much older than his years. He was the author of several works; but he was more given to politics than to medicine, which contributed not a little to his ill success as a practitioner.

TESTIMONIAL.—THE inhabitants of Belper have, at the instigation of its leading inhabitants, generously subscribed to a testimonial fund in favour of Mr. Johnston, who, for a period of more than twenty years, has practised at Belper. The money raised was expended in a brougham, which was publicly presented to Mr. Johnston on Saturday week, accompanied by many gratifying demonstrations of esteem.

## PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

At a meeting of the Committee of Council, held at the Freemasons' Tavern, Great Queen Street, London, on Wednesday, the 17th day of April, 1878—Dr. FALCONER, President of the Council, in the Chair—Resolved: That the Financial Statement for the year ending 31st December, 1877, as audited by Messrs. Price, Waterhouse, and Co., be received, adopted, and in accordance with By-law 33, published in the JOURNAL.

FINANCIAL STATEMENT FOR THE YEAR ENDING  
DECEMBER 31ST, 1877.

April 12th, 1878.

The remainder of the proceedings of the Committee of Council of the 17th instant will appear in next week's JOURNAL.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 9TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

*Myxœdema*.—Dr. ORD showed two cases illustrative of the condition to which he had given the name myxœdema. The main points relative to it were, that it was met with in adult women (both the patients shown were females); they had very much of the aspect of persons in an advanced stage of renal disease, with a flush on the cheek and pallor round the eyes; their speech and gait were slow and uncertain, and their thoughts were slow. They had scarcely any trace of thyroid gland. There was a collection of fat about the clavicles; and the connective tissue was infiltrated with a soft solid œdema containing much mucin—very little of which was found in ordinary œdema or in healthy skin. The mucous œdema was found also on the heart and other internal organs. It agreed with what Sir W. Gull had termed cretinoid disease in adult women.

ON SOME MINUTE POINTS IN THE ANATOMY OF THE KIDNEYS,  
AND THEIR RELATION TO THE PATHOLOGICAL FEATURE OF  
URINARY CASTS. BY REGINALD SOUTHEY, M.D.

The continuous system of the urinary tubules was first described by the author, and traced from their commencement in the papillæ renales up to the Malpighian bodies. He said that the tubuli uriniferi thus commenced in primary excretory oval orifices in the medullary cones, which measured from 0.3 to 0.19 millimètre in diameter. The short trunks into which these opened had no membrana propria, but were set in and bounded by fibrous connective tissue; they each split up into rectangular running branches or gathering mains, and from them perpendicular mounting branches were distributed, which quickly split up again into ascending stems or collecting branches of the third order. These collecting tubes were first branches which could be made out to possess a delicate membrana propria, and to be distinctly lined with a low sessile columnar epithelium, and to present lumina. They measured from 0.0501 to 0.0510 millimètre in diameter; and, while bifurcating at the margino-medullary level into a number of branches, these were all of nearly the same calibre. The collecting tubes curled over into the tortuous tube districts, and became the tortuous tubes, enlarging in size considerably, measuring on an average 0.0201 or 0.033 millimètre, while the epithelium lining their membrana propria nearly filled up their bores. The tubes, however, did not retain their tortuous or glandular characters for long, but turned back into the straight tube columns from which they started, and dropped as Henle's down-loops in juxtaposition with the collecting tubes. These down-loops were the narrowest tubes of all (0.008 to 0.009 millimètre); they were transparent looking, and lined with a flattened and pavement epithelium, surmounted by slightly projecting nuclei; they retraced their passage into the convoluted columns, and once again gradually enlarged in diameter, and acquired the attributes of tortuous or secreting tubes proper. If these diameters and the relation of the secreting system of tubes to the collecting system, the former being directly united to the latter by very narrow midway canals, were considered, it would be ob-

vious that anything like a desquamative shedding of epithelium from the secreting tubes could not pass into the collecting tubes. Further, the size and shape of all casts were found to correspond with the excretory system of renal tubuli. Their most fertile source, Dr. Southey believed to be the collecting tubes or ascending straight tubes of the third subdivision; in these were found the ordinary urate infarcta of new-born children, and the granular and fibrinous casts of chronic renal degeneration. The fine fatty streakings and lime deposits of old persons were seen more strictly limited to the transparent midway channels or down-loops. The largest old fatty granular casts, consisting of cellular debris, leucocytes, fat-dottings, and urinary salts, were doubtless cast or moulded in the gathering mains close to the orifices of the papillæ, but could not be held to be secretions from the tortuous secreting tubes deprived, as had been by some supposed, of their epithelial linings. The author said that the value of casts in deciding the diagnosis, and estimating the advancement of renal diseases had been much overrated, their different forms and appearances were derived in part from the materials of which they were composed, but in greater part were due to the length of time during which the gelatinised plugs of fibrinous material derived from the blood-serum had resided in the passages whose mould they took, the degree in which they had been soaked with urinary salts and stained with urinary pigments, and became degenerated. After many years' vain search for them, nothing like a desquamative shedding of the epithelium lining a tortuous tube had ever been observed by the author; and, although red and white blood-cells, leucocytes, and escaped nuclei had been constantly observed in acute nephritis entangled in fibrinous plugs, actual linings of the straight collecting tubes with their low sessile columnar epithelium had, as such, never been recognised by him. To form any clinical inference as to the nature and extent of renal disease from the sediment of the urine and tubal casts was about as unsafe as forecasting the issue of bronchitis or pneumonia by the expectoration; it was not that the casts or the character of the expectorated matters had no clinical value, but they had a relative one only. In renal disease, the casts should be appraised side by side with the diurnal excretion of urea, and considered in reference to the quantity of albumen excreted at different periods of the complaint.

Dr. GEORGE JOHNSON said that he differed from Dr. Southey in regard to much—indeed, nearly all—that he had said in his paper. He understood that Dr. Southey held that casts formed in the convoluted tubes could not escape through the excretory tubes. If it were so, the study of casts in the urine would be practically useless. Dr. Southey assumed that all convoluted tubes passed through the narrow loops; but this had not been shown, and Dr. Johnson very much doubted that it was so. The statement must be founded on imperfect observation. It was quite certain that casts formed in the convoluted tubes did escape with the urine. The evidence that many urinary casts were formed in the convoluted tubes was indisputable; for instance, in the case of blood casts, the result of hæmorrhage following the use of turpentine, etc. Here it was tolerably certain that the hæmorrhage was from rupture of the Malpighian capillaries, allowing the blood to escape into the convoluted tubes. Again, many casts, especially those of the pure hyaline variety, were more or less convoluted when first passed, proving that they had been moulded in tortuous and not in straight tubes. The white cell-casts were also sometimes very numerous; now, the leucocytes must have escaped from the Malpighian capillaries into the ends of the convoluted tubes; for, on examination after death, the epithelium of the convoluted tubes was found entire, and not displaced by the leucocytes, as it would be if the leucocytes passed through the basement membrane and epithelium of the tubes. Again, fatty disease of the kidney was limited to the cortical portion; and here the urine contained hyaline casts and cells filled with oil-globules, with enlarged and altered cells of the convoluted tubes. The cells of the excretory tubes were rarely, if ever, found to contain oil-globules, while those of the cortex were full of them. Dr. Southey said that he had never seen an epithelial cast of the convoluted tubes; and denied that there was any process in the kidney analogous to desquamation. But cases were constantly met with in which a desquamative process was going on in the kidney, as in cases of scarlet fever and in cases of jaundice when bile was passing off by the urine. The fact that so many casts of different kinds which must have been formed in the convoluted tubes were found in the urine, seemed to show some defect in Dr. Southey's notions regarding the minute anatomy of the kidney. If all the convoluted tubes passed into Henle's loops, every case of inflammation of the kidney must soon be fatal from blocking of the tubes and suppression of urine. Dr. Southey had said that the tubes were not denuded of their epithelium in acute (desquamative) nephritis. Of course they were not; nor was the skin denuded of epidermis in the desquamation following scarlet fever. The old cells of epithelium or of epidermis were

pushed off by newly formed cells beneath. As regarded the size of the casts, there was no doubt that large hyaline casts were moulded in the convoluted tubes; and they were of very uniform size. The small hyaline casts corresponded with the diameter of the free canals of the convoluted tubes retaining their cell-lining; and they varied in size with the condition of the epithelium. The state of the epithelium of the tubes varied in different cases, being sometime swollen and sometimes shrunk and flattened; and small hyaline casts, being moulded in the free canals of the tubes, naturally assumed the size of the canals in which they were formed. All this afforded evidence that casts formed in the convoluted tubes escaped and appeared in the urine, and, therefore, was opposed to the idea that all convoluted tubes passed through Henle's loops. Dr. Southey had said that large hyaline casts were most common in acute disease; Dr. Johnson found them most often in advanced cases attended with atrophic changes in the kidney. The presence of an abundance of them in the urine indicated that atrophy was making rapid progress, and that suppression of urine was not far off. It was quite true that they did appear in acute cases; but much less frequently, and in smaller numbers.—Dr. ANDREW believed that Dr. Johnson's view as to the formation of casts was correct.—Dr. R. D. POWELL asked if it were necessary that all the casts formed should escape from the kidney. Might not some remain and be absorbed, as occurred with the deposits in pneumonia?—Mr. HOWSE had seen, in cases of acute desquamative nephritis from scarlatina, whole tubes filled with perfectly clear cells. They contained no nuclei, and very probably might break down and become absorbed.—Dr. SOUTHEY said that a great deal of matter was probably removed by absorption in acute nephritis, just as in pneumonia. Dr. Johnson had surely seen the excretory tubes blocked with granular casts. It was not correct to assume that the casts were formed in the upper parts of the tube. As to the swollen epithelium producing small casts, the casts being moulded in the tubes, it was a hypothesis not in accordance with experience. Clear transparent casts were found in Henle's down-looping tubes. Much had yet to be made out in regard to disease of the kidney.

ON A GROUP OF SYMPTOMS (OPHTHALMOPLÉGIA INTERNA) INDICATIVE OF DISEASE OF THE LENTICULAR GANGLION.

BY JONATHAN HUTCHINSON, F.R.C.S.

After briefly alluding to the anatomy of the lenticular ganglion, the author stated that its destruction by disease might be expected to be followed by paralysis of three distinct muscular structures, the dilator of the pupil, the constrictor of the pupil and the ciliary muscle. Under such circumstances, the pupil would become motionless and the patient losing the power of accommodation would be unable to read with spectacles. For this condition, involving paralysis of all the muscular structures within the eyeball, the term *ophthalmoplegia interna* was suggested, whilst that of *ophthalmoplegia externa* was proposed in contradistinction for cases in which all or most of the muscles moving the eyeball were involved. The author expressed his belief that examples of both these conditions were met with occasionally in practice, and that the features of each were peculiar and of great interest to neuro-pathologists. His conjecture was that when *ophthalmoplegia interna* existed alone, that is, unattended by paralysis or defect of any of the external muscles of the eyeball, that the disease was in all probability in the lenticular ganglion itself. In venturing upon this diagnosis, as great importance was to be attached to the absence of some symptoms as to the presence of others. If disease existed implicating the nucleus or any part of the trunk of the third nerve, and this paralysing the constrictor of the pupil, there must necessarily be defect of some of the external muscles of the eyeball. The paper next proceeded to narrate the details of eight cases in which the condition referred to was present. None had afforded an opportunity for dissection; and the diagnosis for the present must, therefore, be held to be conjectural only. It was observed, however, that the cases bore a very close resemblance to each other. In none of them was the patient seriously ill, and in but two were there definite indications of implication of other parts of the nervous system. In none did the disease of the nervous system whilst the patient was under observation extend: a fact which might, it was suggested, be in part accounted for by the fact that specifics were used in all. Of the eight cases, in five both eyes were affected. It appeared highly probable that syphilis was in most the remote cause. In three out of the eight, there was no history of syphilis, but in none of these were the facts conclusive as to the negative. All the patients were of an age at which syphilitic affections of the nervous system are common. The oldest was forty-four; the youngest was twenty-seven. In one case, the author had himself attended the patient for severe syphilis four years before the eye-symptoms began. Attention was especially asked to the fact that in many cases the paralysis of the iris preceded that of the ciliary muscle, and almost always in excess of it; and fur-

ther that, under treatment, the ciliary muscle might regain its power whilst the iridoplegia persisted. In no single case was the failure of accommodation the first symptom. A suggestion was made as to the possible association of this group of symptoms with the early stage of locomotor ataxy, especially with that form of it which appears to be connected with syphilis.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, APRIL 16TH, 1878.

CHARLES MURCHISON, M.D., LL.D., F.R.S., President, in the Chair.

DISEASES OF THE LYMPHATIC SYSTEM.

*Relations of Cancer to Lymphatic System.*—Dr. HOGGAN exhibited some microscopic sections, and said this was but a part of the whole life-history of cancer, which could not be introduced then. The specimens were taken from a case of cancer of the skin following the ligature of a mole under the left nipple. It was a very bad type of cancer, and the patient died in eight months from the operation. It illustrated different forms of cancer. In the sweat-glands, it was encephaloid; another part was scirrhus; and a third pigmentary. His conclusions were: 1. When the lymphatic glands are affected, the lymph-vessels are filled with cancer-cells; 2. The lymph vessels on the distal side of the tumour are also filled with cancer-cells; 3. All the lymphatics around are filled with cancer-cells; 4. There are no vessels opening into the cancer masses; 5. Though there are cancer cells in the lymphatics, the epithelial lining is unaffected at first; 6. The epithelia became affected, being softer, so as to take the silver solution; 7. Groups of wandering cells are necessary to the development of cancer-cells in the lymphatics; 8. Fixed cells undergo the cancer-change; 9. Cancer-cells form from wandering cells; 10. Secondary tumours do not affect the lymphatics, because they are already filled with cancer cells, even on the distal side; 11. There is no evidence of the lymphatics affecting the activity of cancer. He then gave the histology of a lymphatic gland, and said wandering cells enlarged in the meshes of the gland.

*Cases of Lymphadenoma.*—Dr. DOUGLAS POWELL showed, for Mr. J. H. PORTER of Netley Hospital, two characteristic photographs from cases of Hodgkin's disease and some sections of the spleen from a case of lymphadenosis. The first case was that of a driver in the Royal Artillery, aged 35, of intemperate habits. Soon after enlistment, he contracted a chancre, followed by a scaly rash and sore-throat; and, two years before his admission into Netley Hospital, he had a second attack of syphilis, with sore-throat. One month after the healing of the second chancre, the glands in the left supraclavicular region began to swell, but were neither painful nor tender. The glands on the right side soon became affected; and six weeks later, the right axillary glands enlarged, then those on the left side, over the ramus of the jaw, and in the occipital and maxillary regions. The sore-throat disappeared as the glands enlarged, but dryness and harshness of throat remained, with spasmodic cough. On admission, the patient was weak, but fairly nourished. The hair on the scalp was thin, and there was no hair on the face. The body was covered with a scaly syphilide. A photograph handed round showed well the glandular enlargements; and attention was drawn to the water-jug represented at the patient's side as evidence of the constant thirst with which he was afflicted. The swellings were hard and nodular, but painless and movable. The front of the chest, the scrotum, the right foot and leg, were oedematous. The patient was unable to lie down from the pressure of the cervical tumour causing dyspnoea and paroxysmal cough. The liver and spleen were not enlarged. The blood showed no lack, either in number or colour, of red discs, but a notable increase in white corpuscles, viz., eighty in a square one-hundredth of an inch. The temperature and urine were normal. The disease progressed steadily, unimpaired by any treatment, to death.—Case II. A corporal of the 12th Regiment, aged 23, was admitted in February 1878. There was no family predisposition or illness prior to enlistment. In May 1874, he was in hospital twenty-one days with inflammation of the glands of the groin, consequent upon pulling off a small wart from the penis. In 1874, he had gonorrhoea. In December, May, and September, whilst at Calcutta, he was treated for rupia and psoriasis by mercurial baths and other remedies. In March 1877, a small lump appeared under the lower jaw on the left side, then a similar enlargement on the right side, both gradually increasing in size and spreading downwards to the clavicle and round to the back of the neck. The glands of the groins and axilla became enlarged, and gradually increased to their present size. This patient was still living, and his present state was well shown in the photograph, which contrasted remarkably with one taken two years previously. He had greatly emaciated, although the appetite was morbidly great. The stools were

not excessive in quantity; the urine, slightly albuminous, contained no sugar. The patient's skin was of an uniformly dusky brown colour, greatly thickened and deeply wrinkled over the head and occiput by solid cedema. The glandular enlargements, well shown in the photographs, were nodulated, soft to the touch, not adherent to skin or tissues, and quite free from pain or tenderness. This patient, too, had lost all hair from the body, and had but little remaining on the scalp or face. The spleen had lately become slightly enlarged, otherwise the internal organs, except the kidneys did not appear to be affected. Dryness of throat and thirst were very marked, and the patient could not lie down without causing severe spasmodic cough. The blood, carefully examined by Dr. Boileau, showed an excess of white corpuscles; but, as in the former case, nothing approaching to leukaemia. The spleen of the third case was handed round. It presented innumerable points of lymphomatous growth, and was greatly enlarged. All the internal glands of the body were enlarged. The lungs were invaded from the mediastinum; and the pleurae, pericardium, and calvarium were bespattered with small nodular growths. The liver was also affected. This patient had been invalided from India for ague, and had died quite suddenly. There was no history of syphilis.—The PRESIDENT said the relations of lymphadenoma to syphilis were interesting.

*Sections from Cases of Lymphadenoma.*—Dr. CHARLEWOOD TURNER exhibited for Dr. SUTTON some drawings and sections from cases of lymphadenomatous and allied conditions. In the first case, there were the enlarged glands of Hodgkin's disease; where there was white new material set amidst hyperæmic patches in the spleen. In another, the spleen from a case of lymphatic disease was delineated. It was enlarged by white opaque masses. The third was an enormous spleen from a boy aged 10, where the glands were not enlarged. The spleen weighed four pounds and a half; there was a history of ague. In other two cases, the kidneys were enlarged. In a boy with Hodgkin's disease, there was general glandular enlargement, and the spleen rather large. The kidneys weighed nineteen and nineteen and a half ounces respectively. The second section was from a case where there was a large spleen. In another case, the vessels of the brain were affected, being full of leucocytes. Some glands in lymphadenoma were hard, and others soft; and this occurred sometimes in the same patient. This was really due to the stage of the disease in each gland. In one case, the enlargement of the glands had nearly disappeared at death. In another case, the spleen grew less. Where there were nodular masses in the viscera, the disease was usually widespread. When the spleen was enlarged, the other viscera, as the liver and kidneys, were affected. Three cases had been recorded where the spleen and glands were not affected in leukaemia. In one, the liver was chiefly affected by an adenoid growth, with intercellular structureless matter. There was also a large amount of fibrous material. Small tubercular bodies were scattered over the peritoneum. Adenoid growths differed from tubercle in the more orderly organisation of their cell-elements; the centre of tubercle was also of a dark colour.—The PRESIDENT remarked that the views last expounded were not in unison with the general tenour of the discussion, and were full of interest.

*Lymphadenoma with Tubercle.*—Dr. DICKINSON referred to the relations of tuberculosis to lymphadenoma. He showed a drawing of a spleen. It came from a lad aged 18, who had a strong tuberculous history, family and individual. He was scrofulous in youth. There were lumps on both sides of his neck, each twice as large as his fist. There were large glands in both axillae and both groins. He had high temperature, reaching 102 degs. at nights. His lungs furnished evidences of tubercle. He soon died of acute tuberculosis. Miliary tubercle was found in the lung, kidneys, and brain. On microscopic examination of the glands, it was hard to distinguish betwixt lymphadenoma and tubercle. In some there was caseation. In one, suppuration had taken place. Clinically, the case was one of lymphadenoma; microscopically, of tubercle. Lymphadenoma occurred in some parts, and tubercle in others. The second case, in a child, so closely resembled the one described that he would not take up the time of the Society in describing it.

*Spleen and Glands from a Case of Lymphadenoma.*—Dr. GARLICK related briefly the history of this case. They came from a boy aged 10, who had enlarged glands on the left side of the neck. His spleen was enlarged. His temperature was high, ranging from 102 deg. in the morning to 104 deg. in the evening. He had diarrhoea. The blood was pale. Later on, there was diminution of both white and red corpuscles. The liver, lungs, and glands were enlarged at death. The cervical glands had undergone some caseation, as had also the bronchial glands. There was new growth in the spleen. There were masses in the liver, with an increase of the reticulum and some giant-cells.

*Tibix from a Case of Lymphadenoma.*—Mr. MACNAMARA exhibited

the tibix from a case of lymphadenoma in a boy aged 9. There were enlarged glands on the right side of the neck, of scrofulous character, which continued to grow, and before death reached an enormous size. There was no suppuration, but they looked like a sarcomatous tumour. The liver and spleen were not large. The boy died of pleurisy. He injected the femoral artery in water to examine the medulla of the leg-bones. In the blood, there was no increase of white corpuscles. He found that the injection had not penetrated beyond the larger branches of the nutrient arteries of the bones. The open spaces were filled with a cellular growth like those in the glands. They resembled the bones in tubercular affections. These growths caused pressure on the sinuses, and so the injection could not pass. The osseous structure was unimpaired. The cell-growth penetrated into the epiphyses. The deeper layers of the periosteum contained the descendants of cartilage-cells; and it was from these that the callus grew, and also from these nodes are formed. These cartilage-cells extended into the medulla. This growth spread out like a malignant disease. It was a specific disease, quite unlike ordinary enlargement of the spleen, which was common among the natives of India, in whom lymphadenoma was unknown. Tubercle, too, was rare among them.

*Lymphadenoma with Struma.*—Dr. MORRISON related a case of this nature. It occurred in a girl aged 7, who had Hodgkin's disease. She was a twin; and her twin sister died of the same disease after an injury to the head. All the children of the family were strumous; and the mother was debilitated by rapidly repeated pregnancies.

Dr. PYE-SMITH said that the first cases of leukaemia were described as a development of pus-cells in the blood. Virchow's term of leucocythæmia showed a right appreciation of the nature of the malady. Pathology could add nothing. The question was (1) whether the leucocytes swamped the red corpuscles; or (2) whether there was a relative increase from diminution of the red corpuscles. It was certainly not the latter. There was an increased production of leucocytes from the hypertrophied spleen. When the leucocytes from leukæmic cases were watched in the warm stage, it was seen that they did not possess amoeboid movements. This might be from imperfect development from rapid formation. These white corpuscles did not develop into red, and so accumulated in the blood. In Hodgkin's disease, there was no leukaemia except in a few rare cases. In nearly all, there was inflammation about the lymphatic glands; and there was pyrexia. The leucocytes gather in the glands in allied forms to Hodgkin's disease. He would suggest the term "lymphosis" for Dr. Gowers's "lymphadenosis". There was an anæmia myogenetica, as in Mr. Macnamara's case. There were cases where glands were enlarged with anæmia, as the tonsils, for instance, as was the case with the glands ordinarily affected. He then referred to the case of idiopathic anæmia detailed by Sir William Gull and Dr. Dickinson at the last meeting. It was a fatal anæmia without lymphoid disease, quite different from ordinary anæmia, in that iron did no good whatever. He said essential anæmia was fully described by Dr. Addison in 1855, though the fact seemed to have escaped the attention of some recent foreign writers, who had not added one important fact to Dr. Addison's description.

Dr. MOXON said that no doubt, as it had been assumed by the Society that the diseases brought together formed a natural group or class, there must be good and sufficient reasons for this. But these reasons had not yet been made very apparent. Their claim to relationship he supposed to be chiefly through their extending over a certain selection of organs, namely, the spleen and the lymphatic glands. Dr. Goodhart had spoken intelligently of this as mere malignant generalisation, as if it were ordinary spread of malignant disease. But Dr. Moxon supposed that, if in Hodgkin's disease the tumours of the glands were associated with secondary tumours in the lungs and liver, nothing very special about them would ever have been heard. But the spleen was comparatively rarely a seat of secondary growths in ordinary malignant disease, and then only to a slight extent, and in the form of round bold masses of spreading tumour. In Hodgkin's disease, however, there was a remarkably frequent implication of the spleen, and the masses were not like ordinary malignant tumour; they were angular looking pieces rather than round tumours. And it was no doubt by the curious common association of seat in glands and spleen that the diseases grouped for discussion were connected. But, even this common bond of harmony left Dr. Moxon in wonder how idiopathic anæmia could have been cast into the group; for idiopathic anæmia was not attended with disease of the spleen or glands. It was the very simple thing that Addison had well described it to be, as just stated by Dr. Pye-Smith. He had been disappointed with the effect of the discussion, which he had hoped would have been in accordance with the etymological signification of the term—to shake apart; so that these diseases should have been so shaken apart as never to come together again. He was glad to hear the President decide that the evidence showed that there

was no leukaemia in Hodgkin's disease. That, indeed, was abundantly clear. It was true that a moderate augmentation of the white cells in the blood was a frequent thing in many diseases; and such an augmentation to a small extent would occur in Hodgkin's disease, but nothing like a true leukaemia. Take, as an example, what might have, but for an accident, been used as a typical example of that false kind. A lad was sent into Dr. Moxon's ward, a few days ago, as a case of leukaemia lymphatica, or leukaemia with Hodgkin's disease. On carefully counting the white cells, however, they showed only one to twenty-seven red; and when the boy died it was found that the disease of the glands was true cancer, and it spread to the liver, not the spleen. Such a case was a type of the few confusing cases which gave rise to the false reports of lymphatic leukaemia. They were very rare, not less rare than such cases as Dr. Dickinson had just shown, of a mixture of lymphadenoma with tubercular disease in the same subject. Such a case Dr. Moxon showed some years ago. These cases were not allowed to confuse tubercle with lymphadenoma. Neither should a few doubtful mixed looking cases confuse Hodgkin's disease with leukaemia. In fact, a small increase of white cells in the blood no more constituted leukaemia than a small increase of sugar in the urine constituted diabetes. Dr. Moxon would venture to maintain his own view of leukaemia. He did not accept Virchow's view of a leukaemia made from the glands, and another leukaemia made from the blood, to which of late had been added a third leukaemia made from the marrow of the bones. This view was founded, it was true, on the best modern teaching as to the origin of blood-cells; but he ventured not to be satisfied that all was known about the origin of blood-cells. It was assumed they arose in one's neck and armpits and groins in glands, placed apparently to stand in the way against gonorrhoea, scarlatina, and such like; and that they arose in the spleen—a very different looking organ, very differently placed; and lately it had been taught they arose in bone-marrow. The evidence was of two kinds. First, some—Rouget and Kölliker for instance—were said to have seen the change of white lymph-cells into blood-cells. He had great respect for microscopic observation, but preferred, for so large a question, some means in which other senses could go to the help of the eye labouring down a microscope. The other evidence was this question—Since the glands are always pouring lymph-cells into the blood, where do they go if they do not turn red? The answer was not far now, that it was known that white cells wandered out of the blood into the lymph-spaces, so that there appeared to be a circulation of white cells into and out of the blood. Indeed, this theory of white blood-cells turning flat and dark was too simple. Dr. Moxon had watched the division of white cells in the blood of the larval oniscus, and seen the whole process of the division, and he believed the blood to be more independently alive than Virchow's theory of leukaemia and the modern physiology of the blood supposed. He believed that in true leukaemia the blood itself was primarily diseased, so that Dr. Hughes Bennett in his first impression of his case was much more right than was usually supposed when he called the disease suppuration of the blood. The blood increased the number of its white cells, and these outwandered in greater numbers into the tissues and got into the lymphatic channels; and, if from any accident they could not pass the glands, there was a swelling of these, secondary in its nature, but deceiving Virchow into the view of "lymphatic leukaemia". Then the spleen was an organ ready always to sympathise first in difficulties of circulation, and when the white cell-blood went round with trouble in the spleen, it was accumulated with excess of the white cells. In the hard channels of bones, the veins could not swell with the thickened blood, so that the blood stagnated in the marrow, and white cells passed out into the marrow, whence the story of marrow-leukaemia. Thus all the facts of leukaemia were to be deduced from a haemal pathology of the disease; and the enlargement of the spleen, and occasionally of the glands, of leukaemia was altogether different from that of Hodgkin's disease. But Hodgkin's disease, without any association with leukaemia, was a most interesting disease, because of its implication of the several lymphatic structures. Dr. Moxon would regret the losing sight of its peculiarities in a general term like lymphadenoma. Indeed lymphadenoma would not serve the purpose of the name Hodgkin's disease, which was useful in keeping before the profession a recognition of the remarkable series of chronic diseased changes to which the name applied. The swelling of glands, especially those in the neck and the implication of the spleen, etc. But lymphadenoma was a much more inclusive term. Thus the Committee on Morbid Growths had applied the term to a case of cancer of the bones. Hodgkin's disease was but one of the forms of lymphadenoma, and this form of it was a large glandular tumour behind the peritoneum, extending down the lacteals to the intestines, and invading the intestine with the effect of widening it and causing diarrhoea. This form of intestinal disease, Dr. Moxon believed, must be set down

amongst the causes of fatal chronic diarrhoea, and he had before drawn attention to it without wanting to attach his name to the disease. True these diseases had the same micro-anatomy, but he could not help thinking too much might be made of such a fact, whose importance is still under the microscope. He had been much interested in the admirable report, by the President and Dr. Sanderson, in vol. xxi of the *Transactions*, upon a case of lymphadenoma of the neck, spleen, etc.; but he thought the able description rather went against that term; for the structure was exceedingly simple, almost as simple as blood-clot. Dr. Sanderson, however, fixed his attention on a certain concentric arrangement about vessels, and identified this with the adenoid tissue of His. Concentric arrangement around vessels was common to many forms of pathological action. Tubercular meningitis and lupus showed it; so did even that sclerotic change which Sir W. Gull and Dr. Sutton plentifully illustrated last year. Dr. Moxon thought that the pathological value of the microscopic kinds of likeness could be well measured by looking at what Virchow included under his lymphoma. He puts there leukaemic tumour, tubercle, typhoid intestine and scarlatinal tonsil. What was the goal of a criterion of likeness that juxtaposed all these things, so wholly dissimilar in all essential bearings, in their genesis, their characters, their course, and their results? To be mutually lymphoid was on the very outskirts of any true relationship. For a tissue to be lymphoid was much the same as for a crystal to be rhomboid, as far as either fact was *à propos* of the true nature of the respective substances. The cause which started Hodgkin's disease might be one thing, and the cause which started retroperitoneal lymphadenoma a thing as different as scarlatina from leukaemia. What was wanted was to draw our pathology always into closer union with clinical significance, even if the morphological alliances of clinically and pathologically distinct disorders had to be partly set aside.

## CORRESPONDENCE.

### THE TITLE OF DOCTOR.

SIR,—I observe that, in your issue for the 30th ultimo, you speak of it as a "grievance" that "the great proportion of English medical men are debarred from the use of the title of Doctor"; and you infer that the chance offered by the Duke of Richmond's Bill should be availed of to place that title at the disposal of all licensed practitioners. I beg permission to remind you that it is already entirely open to them, if they are prepared to gain it by the requisite study; and I certainly do not regard it as any "grievance" that a person who declines the trouble, delay, and expense of winning such a decoration, should be denied the right to wear it. I perfectly understand your complaint that licentiates of Durham, St. Andrew's, and the Queen's University are permitted to call themselves M.D., while those of other Colleges—quite as deserving of the title—are not so permitted; but I altogether deprecate your remedy for the anomaly by levelling down; and I maintain that, on the contrary, the Duke of Richmond should level up by means of an enactment that no person should be granted a Doctorate in Medicine until he had previously taken a full degree in Arts. You are aware that, up to a recent period, the state of things was that which I suggest, and you will admit that the affix M.D. conveys to the general public the impression that he who uses it is an University man, and that he combines with his medical qualification the liberal education demanded from an Arts' graduate. You may also, probably, be aware that the General Medical Council has affirmed the proposition that the M.D. should not be granted to any but the holder of a full Arts degree.

I, therefore, submit that the use of the letters M.D. by any University, to indicate a mere licence to practise, amounts to the obtaining of professional credit for their licentiates from the public upon an unjustified pretence; and that it ought to be, therefore, withdrawn. Medical men covet the M.D. and the title of "Doctor". Why? Because they know that it carries with it the *prestige* of an University education, and that that *prestige* counts for something in the competition for high-class practice. Is it reasonable that they should demand that *prestige* without earning it? And, if they acquire it on such terms, how long will the Doctorate continue to carry with it the least public estimation? A ready-made subordinate position in the profession are occupied by *several* M.D.s; and it is sufficiently evident that, if all licentiates are to be dubbed M.D., that title will, in a few years, possess no more value as a distinction than L.R.C.S. or L.F.P.S. What, then, will the profession have gained? And will not a loss have been sustained by the abrogation of a title which has been so long sought for as an University honour?—I am, sir, yours, etc.,

ARCHIBALD H. JACOB, M.D. Dub. Univ., F.R.C.S.I.

23, Ely Place, Dublin.

# THE UNIVERSITY OF DURHAM AND THE M.D. DEGREE.

SIR,—The discussion that has from time to time taken place in your columns as to the title "Dr.," and the demand there is amongst men already in practice for some way to gain undisputed right to the use of that title, has so far led to no practical result.

I am one of the many who suffer under what is to me an unfortunate disability in this matter. Unable to spend time and money during my student career for the attainment of a degree at the London University, and, being a student at a London school, shut out from the Scotch Universities, after some years of practice, I find that the M.D. would be of considerable service to me, and I am ambitious to wear an honourable degree. The disability is here: I must either wait till forty (ten years), or perhaps till fifty, for the chance of being one of ten at an University across the border, or pay a visit in ten years to the University of Durham, or take a journey to the Continent; in this last case, not being able to register my degree. At thirty, I am busily employed, and should have to scheme much to do systematic reading for an examination; and, by the time I am forty years of age, spare moments will be few, and my opportunities for cultivating the kind of practice I seek have greatly lessened, perhaps have gone. I have debated a visit to the Continent, but would cheerfully wait if there were any hope, at an early period, of the Universities of England coming to our help. I would venture a suggestion towards the removal of this disability. The University of Durham has already opened its doors to qualified practitioners, of fifteen years' standing and of the age of forty. The standard of examination seems a good one, and the degree one that might be worn with honour; but the concession does not go far enough. Cannot the University, without in any way deteriorating from the quality of the degree, throw it open to all medical men of eight or ten years' standing, after the fashion of the modified examination for the Fellowship of the Royal College of Surgeons? It would be a stimulus to work also to have, in connection with the examination, a pass-list and an honour-list; and it would be well to make some reduction in the fee, which, in the case of many with growing families and growing expenses, is at present almost prohibitive. Such alterations would enhance the value of the degree and increase the number of applicants. A move of this kind, on the part of the University of Durham, would confer a boon on many aspiring practitioners; it would tend to the increase of knowledge, by holding out a reward just at the time when the mind is most vigorous and practice is being shaped; and would most certainly not be unfair to men who earned perhaps a better degree, so far as extent of book learning is concerned, but with less matured mind and judgment.

I hope that this suggestion will gain the attention of those able to help.—I am, yours truly,  
April 5th, 1878.

M.R.C.P.

## THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

SIR,—Will you read the enclosed copy of correspondence relative to the coming election of the Council of the College, and give it space in the BRITISH MEDICAL JOURNAL, with any remarks you may think right?—Yours sincerely,

GEORGE POLLOCK.

36, Grosvenor Street, W., April 11th, 1878.

*Copy of Letter to Mr. Pollock.*

"Edinburgh Chambers, 12, King Street, Manchester.

"Dear Sir,—There is a strong desire on the part of many distinguished Fellows of the College of Surgeons to see Mr. Lund elected to the forthcoming vacancy in the Council of the College as a representative of Provincial Fellows. He has for many years occupied a prominent, and of late a foremost, place among surgeons in Manchester, and for more than a quarter of a century has been actively engaged in lecturing and hospital work. His position in the scientific world, and his many and valuable contributions to surgical literature, are too well known to need mention by me.—Sincerely hoping you may be induced to sign the enclosed memorial, I am, my dear Sir, yours truly,

"April 5th, 1871."

"S. MESSENGER BRADLEY.

[Here followed a copy of the requisition to Mr. Lund, which was published in last week's JOURNAL.]

*Copy of Mr. Pollock's Letter to Mr. Bradley.*

"35, Grosvenor Street, W., April 11th, 1878.

"Dear Sir,—I beg to acknowledge the receipt of your circular relative to the election of Mr. Lund to the Council of the College of Surgeons. In reply, will you allow me to say that I have always steadily refused to be nominated for the Council, as I consider the 'certificate

of character' required by the Charter, and the usual canvassing that takes place prior to the elections to the Council, derogatory to the profession? The College of Physicians does not require or permit anything in the shape of the former, and would condemn, if not punish, anything approaching the latter.

"The canvassing that has been permitted and undertaken by some of the candidates for seats in the Council is really a disgrace to the Fellowship.

"Entertaining the feelings I do, you will understand my objection to signing any paper in reference to the coming election in behalf of any candidate. No one will be more pleased to see Mr. Lund a member of the Council than myself. I have the highest opinion of his work and worth as a surgeon. But, in my opinion, whatever that may be worth, his election should not be dimmed by private or public solicitation of votes.

"I think this subject one of so much importance, that I have enclosed copies of the correspondence to the medical journals.—Believe me, yours faithfully,

GEORGE POLLOCK.

"S. Messenger Bradley, Esq."

## THE CIRCULAR OF THE MEDICAL REFORM COMMITTEE.

SIR,—It is very fortunate for me, as having to receive, read, and collate the answers to the circular issued by the Medical Reform Committee, that all who receive it do not reply at such great length as Dr. Gairdner, and do not consider it necessary to drag the career of the late Emperor of the French or equally irrelevant affairs into the arena.

Dr. Gairdner gives us his opinions about the late Emperor in a very offhand manner, and dismisses with a sneer the one ruler of France who, while proving himself the fast friend of England, raised the material prosperity of his country to such an unexampled pitch that, notwithstanding the extortionate exactions of Germany after her crushing defeat, France still remains one of the great powers of Europe, equally prepared with England itself for every eventuality.

Dr. Gairdner may or may not be aware that many of the wisest heads in Europe believe that France was saved from the Red Republic and Communism by the *plébiscite* which made the so-styled "Man of Sedan" the arbiter of the destinies of his country during a period of twenty years, and the founder of Italian unity.

I demur, however, *in toto* to Dr. Gairdner's attempt to place the members of the medical profession of the United Kingdom on a level with the ignorant peasantry and wild town-population of France. There is nothing in common between them but that instinct which, having guided the French to save their country from anarchy, will, I hope, also guide the profession in this country to bring something like order out of the conflict of interests and of disorder in which some of the licensing corporations have so long kept us.

The question of medical reform is not new to the Association. You, sir, have clearly shown, in your article in the JOURNAL of the 13th instant, that, but for the action of the Association, there would have been no Medical Act of 1858. The principles advocated by the Committee were advocated by the Association before the passing of that Act; they have been repeatedly approved and laid down since; they are included in the drafted Bill of the Association.

The Medical Reform Committee in the present day follows the example of the Medical Reform Committee in existence before 1858 in suggesting and printing a form of petition for the use of those, but of those only, who agree with the Committee. There seems no probability of Dr. Gairdner being beguiled into adopting it. Further, in issuing the circular the Committee had truly only one object. They desired to ascertain, as far as in them lay, the desire of the profession on the two points mooted, and for that reason did not confine it to the members of the Association. No better mode of proceeding could well be devised.

Well, the circular was cast forth. Dr. Gairdner replies, as he states, as 1-20,000th part of the profession. If the remaining 19,999 are to answer at equal length, my work becomes simply impossible. Dr. Gairdner has not made me a direct return; but, from his letter, I presume I am right in recording him thus.

1. Are you of opinion that the medical profession should be directly represented in the General Medical Council? *Answer:* Yes; but do not see how. *Ergo*, doubtful.

2. Are you of opinion that the establishment of a conjoint board for the granting of licences to practise all branches of the profession should be made compulsory in each of the three divisions of the kingdom? *Answer:* Certainly not.

I sincerely hope that all other members of the profession who agree with Dr. Gairdner, and who have not yet returned the circular, will be content with Dr. Gairdner's exposition of their case, and reply in the simple, short, and, to me, more satisfactory manner, which I have ventured to indicate.—I remain, dear sir, yours faithfully,

EDWARD WATERS, Chairman of the Medical Reform Committee.  
Chester, April 23rd, 1878.

#### FATAL CASE OF CARIES OF EXTERNAL MEATUS.

SIR,—With reference to the case with the above title, published in the JOURNAL of last week, Dr. Gumpert, the physician in attendance on the patient, has kindly pointed out one or two inaccuracies in my report, which I had not seen since forwarding it for insertion last November.

I need hardly say that my opening remarks applied to this class of affections in a general sense, and by no means to Dr. Gumpert's diagnosis, which was perfectly accurate, and the full nature and gravity of the case pointed out to the relatives at once. The statement that this patient had syphilis is incorrect, and, together with the remark, that the illness began on Saturday (it was a day later), are errors for which my notes—written from memory on the day of the patient's death from Dr. Gumpert's account—are responsible. I regret that Dr. Gumpert had not an opportunity of revising the history of this case before publication.—I am, etc.,  
F. M. PIERCE.

Manchester, April 24th, 1878.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on April 18th.

Chevers, Norman, H.M. Indian Army, of Tavistock Road: diploma of membership dated January 8th, 1847.

Donald, Deputy Inspector-General John, of Wilmslow, Cheshire: September 4th, 1835.

Freer, Walter Carless, of Birmingham: October 5th, 1841.

At the same meeting of the Council, the following gentlemen were elected Fellows under Section V of the Charter of 18th Victoria, relating to members of the College of twenty years standing.

Fayrer, Sir Joseph, K.C.S.I., F.R.S., Granville Place, W.: diploma of membership dated July 9th, 1847.

Pemberton, Oliver, of Birmingham: April 12th, 1847.

The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on April 17th.

Andrew, John E., Victoria, Australia

Anand, George, Melbourne, Australia

Atkinson, John M., Winchester (London Hospital)

Berry, Frederic H., Anwell Street, E.C. (Guy's Hospital)

Colenso, Robert J., Phillimore Gardens (St. Bartholomew's Hospital)

Evans, Edward T., Llanfalon, Glamorganshire (Middlesex Hospital)

Fardon, Edward A., Droitwich, Worcestershire (Middlesex Hospital)

Giles, Bernard F., Canonbury (Guy's Hospital)

Higgs, Alfred, Leicester (London Hospital)

Lavis, Henry J. J., Stalbridge, Dorset (University College)

Lockwood, Charles B., Stockton-on-Tees (St. Bartholomew's Hospital)

Nicholson, James E., Tours, France (St. Bartholomew's Hospital)

Sylvester, George H., Tonbridge (St. Bartholomew's Hospital)

Four gentlemen were approved in Surgery; and, when qualified in Medicine, will be admitted members of the College. Five candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 18th, 1878.

Burnie, William Gilchrist, Bradford, Yorkshire

Rickitt, John Dennis Thorpe, Wainfleet, Lincolnshire

Smith, Kenneth Rawlings, Oak Villa, Stamford Hill

Wells, Charles, Hillside, Stowmarket

#### MEDICAL VACANCIES.

THE following vacancies are announced:—

BELGRAVE HOSPITAL FOR CHILDREN—House-Surgeon. Applications to be made on or before May 15th.

BRISTOL ROYAL INFIRMARY—House-Surgeon. Salary, £100 per annum, with board, furnished apartments, and washing. Applications to be made on or before May 1st.

BROMYARD UNION—Medical Officer and Public Vaccinator for the Parish of Cradley. Salary, £50 per annum, and fees. Applications to be made on or before May 4th.

GERMAN HOSPITAL, Dalston—Honorary Assistant-Surgeon. Applications to be made on or before May 1st.

GLOUCESTER GENERAL INFIRMARY—Surgeon and Assistant-Surgeon. Applications to be made on or before May 30th.

GREAT NORTHERN HOSPITAL—Ophthalmic Surgeon. Applications to be made on or before May 6th.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street—Assistant-Surgeon. Applications to be made on or before May 15th.

LEITH HOSPITAL—House-Surgeon and Assistant-Surgeon. Salaries, £70 and £60 respectively, with board. Applications to be made on or before May 15th.

LIMERICK UNION—Visiting Medical Officer for the Workhouse. Salary, £75 a year. Candidates must be over 23 years of age, and must attend personally at the day of election; viz., May 6th.

LIVERPOOL DISPENSARIES—Three Assistant House-Surgeons. Salary to commence at £108 per annum, with fire, gas, and attendance. Applications to be made on or before the 30th instant.

METROPOLITAN FREE HOSPITAL, Commercial Street, E.—Two House-Surgeons.

SHEFFIELD PUBLIC HOSPITAL and DISPENSARY—Junior Resident Medical Officer. Salary, £50 per annum, with board, lodging, and washing. Applications to be made on or before May 6th.

STROUD GENERAL HOSPITAL—House-Surgeon. Salary, £60 per annum, with board, furnished rooms, and washing, and £30 per annum in lieu of stimulants. Applications to be made on or before May 15th.

TAUNTON UNION—Medical Officer and Public Vaccinator to the Churchstanton District. Salary, £52 per annum, and fees. Applications to be made on or before the 28th instant.

UNIVERSITY COLLEGE, London—Professor of Materia Medica. Applications to be made on or before May 15th.—Surgical Registrar. Applications to be made on or before May 6th.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea—House-Surgeon. Salary, £50 per annum, with board and lodging. Applications to be made on or before May 18th.

WILTS COUNTY LUNATIC ASYLUM—Assistant Medical Officer. Salary, £110 per annum, with board, lodging, attendance, and washing. Applications to be made on or before May 15th.

#### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

\*BODDY, H. W., M.B., appointed Assistant-Physician to the Clinical Hospital and Dispensary for Children, Manchester.

GRIFFARD, R. Henry, L.D.S.R.C.S. Eng., appointed Dental Surgeon to the Royal Albert Hospital, Devonport.

\*MASSIAH, B. J., M.B., appointed Resident Medical Officer to the Convalescent Hospital, Cheddar, Manchester.

SOUTHAM, F. A., F.R.C.S., appointed Resident Surgical Officer to the Manchester Royal Infirmary.

STEELE, G., Esq., appointed Resident Medical Officer to the Manchester Royal Infirmary.

TOMKINS, Henry, M.D., appointed Resident Medical Officer to the Mosaic Fever Hospital, Manchester.

#### BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

##### BIRTH.

BIRT.—On April 15th, at Stourbridge, the wife of \*George Birt, M.B., of a son.

##### MARRIAGES.

BINDLEY—JACQUES.—On April 12th, at Remenham, Henley-on-Thames, Philip Bindley, M.B. Lond., to Sarah Bessie, only daughter of the late William Jacques, of Clifton.

LAVIN—WIGAN.—On April 24th, at St. George's, Hanover Square, by the Rev. William Falconer, M.A., Rector of Bushey, Herts, assisted by the Rev. Charles Phillips, M.A., Vicar of St. Matthew's, Oakley Square, \*Dr. Drury Lavin, late of Park House, Bushey, to Sophia Matilda, widow of Alfred Wigan, Esq., of Heatherden, Iver Heath.

##### DEATHS.

\*JACKSON, Thomas Carr, F.R.C.S., on April 23rd, at 91, Harley Street, Cavendish Square, aged 55 years.

\*MATHERSON, Robert Samuel, M.R.C.S.L., L.K.Q.C.P.L., of Birmingham, on April 7th, aged 39 years.

MOORE.—On Easter Day, April 21st, at 40, Fitzwilliam Square West, Dublin, Ellie (Elsie), aged 23 years, the beloved wife of \*John William Moore, M.D., and only daughter of the late John Ridley, M.D., of Moore Hall, Tullamore, King's County.

DONATIONS, ETC.—The Misses Brooke have given £500 to the Hospital for Incurables, near Dublin, which, with a previous donation, makes a total of £700 contributed to this institution.—The late Mr. William Coates has bequeathed £200 to the Belfast Royal Hospital, and £100 to the Belfast Hospital for Sick Children.

An illuminated address was recently presented to Dr. Richard Lord by the Church Coppenhall Horticultural Society on the occasion of his leaving Crewe, where, besides being a very active member of the Society, he has occupied the position of Medical Officer of Health.

## OPERATION DAYS AT THE HOSPITALS.

- MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.
- TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.
- THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.
- FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY.**—Medical Society of London, 8.30 P.M. Mr. Mason, "Case of Congenital Deformity of Rectum" (living specimen); Mr. Thomas Bryant, "On the Surgical Treatment of Intestinal Obstruction"; with Two Cases of Enterostomy.
- WEDNESDAY.**—Obstetrical Society of London, 8 P.M. Specimens: Sections of an Uterus on the first day of Menstruation, showing Desquamation of the Decidua; Section of Dysmenorrhoeal Membrane (Dr. Cory); Fractured Fœtal Skull (Dr. Poole); Case of Hand-behind-Head Presentation (Dr. Fryden). Papers: Dr. Braxton Hicks, "Case of Cesarean Section"; Dr. Potter, "Case of Pregnancy complicated with Malignant Growth in Vagina and Rectum"; Dr. R. Cory, "Membranous Dysmenorrhœa"; Royal Microscopical Society, 8 P.M. Mr. A. D. Michael, "On new British Cheyleti".
- THURSDAY.**—Harveian Society of London, 8.30 P.M. Dr. Buzzard, "A Case of Blepharospasm"; Mr. Edmund Owen, "A Case of Epithelioma of Rectum"; Dr. John Williams, "Cases of Fibroid Tumour treated by Hypodermic Injection of Sclerotic Acid".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

## UNCOMMON FORMS OF DISLOCATION.

SIR,—Under this heading, in the *JOURNAL* of April 6th, Mr. Robson mentions dislocation of the jaw occurring during an attack of hysteria. Though such cases may not be recorded by the authorities Mr. Robson quotes, I do not think they are unknown to the majority of practical surgeons. As a case in point, I may mention the following. Some time ago, I was hurriedly called to see a lady who was reported to be *in articulo mortis*. The friend I saw first that two days previously she had had a fit, which was immediately followed by facial distortion (the mouth remaining widely open), and inability either to speak or swallow. A medical man had called in, and pronounced the case a "severe attack of apoplexy", and administered a turpentine enema. The history of the attack was clear, and left no doubt whatever that hysteria had to answer for the evils the lady suffered. Dislocation of the jaw was plain, and, under the persuasive influence of a little manipulation, the (so-called) apoplexy vanished, the drawn features returned to their normal position, the power of swallowing, so necessary to life, and the power of speaking, almost equally necessary to woman-kind, were happily recovered. It was the end of a little fairy tale.

I may add, that the enema did not prove of any absolute value in this case, nor that its administrator has since been remembered in the prayers of an ungrateful patient.—I am, etc.,

Manchester, April 1878.

J. N.—Mr. Howard Marsh, Mr. Berkeley Hill, and Mr. Barwell, have lately published reports of cases successfully treated by Sayre's suspension method and plaster jacket.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

## MEDICAL ETIQUETTE.

SIR,—Under the above heading, you have published a paragraph in your issue of the 20th April (p. 583) relating to my advertisement of scale of charges. You state that you will be very happy to publish the opinion of any medical authority on the subject; but before making any remark on that head, permit me to repeat that your libellous paragraph of the 6th instant, which was of a most malicious character, and which you have now followed up by another, to the effect that I have done something very wrong, as not being "consistent with the generally accepted notions of professional propriety among the medical profession in this country", has been used directly to damage my professional character; and that, as you have been informed through my solicitor, W. M. Skinner, Esq., of Sunderland, the paragraph of the 6th instant has been copied from your *JOURNAL* into the *Sunderland Daily Echo*, with a manifest intention to damage me. I beg also to inform you that copies of that paper, with the paragraph marked, have been sent to some of my country patients, and to one gentleman in particular, upon whom I had performed lithotomy. As my solicitor has informed you, medical men have asserted that, through your paragraph, I would lose my licence and be struck off the *Register*. Therefore, for the sake of justice, and to prevent having the question settled in a court of law, I demand from you an apology, published in your *JOURNAL*, to the effect that I have not acted against the rules and discipline of the Apothecaries' Society, or any other society to which I am amenable. I claim to know what true professional propriety in this country is, as well as the editor of any medical journal. Have I not finished a full curriculum of four years at the College of Medicine, Newcastle upon-Tyne, University of Durham? You say your Association claims to uphold a high standard of professional propriety amongst medical men. I claim to do the same. But are you now doing it in the way it should be done? Has not your Association admitted, and does it not admit as members, medical men who style themselves "Doctors", and have "Dr." on their doorplates and elsewhere, without ever having passed an examination as such at any university, and, therefore, of course holding no doctor's diploma? Not only so, but other members of the so-called medical profession, who never passed an examination in chemistry, do or did hold office in your Association. I was once, as you know, a member of it, and the reason why I left it was, that its order of professional propriety was not high enough for me. You would refer me for an opinion on the subject of my advertisement (published in self-defence) to the Council of your Association. I know that many highly educated men of the most unexceptionable professional mark and standing are members of it; but that does not alter the fact, that the Association includes an abundance of self-styled doctors who have no good title to be called such. I therefore decline to be judged by such an anomalous body, or to square my conduct according to its *dictum*. Those who live in glass houses should not throw stones. I thank Heaven that neither you nor your Association are any legal authority, nor have you any power to give a legal opinion. As to your second proposed reference—to the Council of the Apothecaries' Society—I have nothing to do with that body. When I presented myself to its Courts of Examiners in 1868, I satisfied these gentlemen, and passed my examination, receiving, therefore, my diploma. In accordance with the Society's Royal Charter, I have a right to publish my scale of charges, whether spontaneously or in self-defence, and I need no further reference. I have the letter of the law and the spirit of good law, which is justice and common sense, to protect me; and as I claim to have as legitimate a professional standing as any medical man in England, I shall defend my professional character wherever, whenever, and by whomsoever impugned, before the highest court of appeal that exists.—I am, yours truly,

GUSTAV ARRATH, M.D., etc.; late Voluntary Surgeon at the War Hospitals, Courcelles, Investing Army, Metz; Medical Conductor of a Sanitary Train Railway between Pont-à-Mousson and Saarburg; Eisenbahn Erappen-Arzt Third Army at Eprenay; Medical Member of the Royal Evacuation Commission of the German Army at Eprenay; Physician and Surgeon to the Military Hospital at Strassburg.

Sunderland, April 23rd, 1878.

**AN OLD ASSOCIATE (Pontpool).**—We are inclined to think that the master is liable for the servant; and if the message summoning an Old Associate were delivered by one of his agents in his name, there can be little doubt on the subject.

## "COMMISSIONS."

SEVERAL correspondents forward us copies of the subjoined enclosure, with expressions of such indignation as may naturally be aroused by an insult of the kind. We cannot understand how the author of this circular can permit himself to make offers so grossly insulting to the respectable members of the medical profession. The statement with which the circular opens is one which cannot be read without disgust; but it must be taken for what it is worth, and in connection with the circumstances in which it is made a part of an advertising circular. There are black sheep in all callings, and the author of this circular may have had dealings with them, but this does not justify his insulting the respectable members of the profession in his district by addressing such offers to them.

"Dear Sir,—For a considerable period it has been my practice to remunerate medical men for the honour they do me in recommending me to their patients. Finding that this system begot a feeling of mutual confidence, I have determined, in every case of recommendation by medical men, to present them with a fourth part of the sum received. I estimate my profits at fifty per cent., and in every case I shall allow twenty-five per cent. to the medical man recommending me. I need scarcely add, that my system is one combining nature with utility, and renders mastication an easy and comfortable performance. I may here state that my attention has been very much directed to the regulation of children's teeth by means of invisible gold plates, thus arresting the deformities of the mouth, which would otherwise take place. I may add, that in consequence of the attention bestowed, I invariably give perfect satisfaction. This is a subject well worthy your consideration, as it is astonishing the sums I pay even to men in comparatively small practice. It is desirable that in every case you will instruct your patient to hand me your card or name and address.—I am, yours very truly, —, Surgeon Dentist.—P.S. On completion of a case or operation, I will immediately forward you a cheque for the percentage due."

**ERRATUM.**—In the *JOURNAL* of April 6th, page 489, column 1, line 7, for "oligopyreæmia", read "oligapyrenæmia".

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

**KOUMISS.**

SIR,—I do not think that "A Physician" is confounding the really fermenting koumiss and the spirituous liquor distilled from mare's milk, which is of an intoxicating character. In referring to Dr. Jagielski's book on *Koumiss and its Use in Medicine*—at present, I am told, out of print—I find on page 8 that "the koumiss of the Kirghises is prepared from mare's milk in summer, but during winter (when mare's milk fails them) from cow's milk, and this they call airen, argen, or argan. The koumiss which contains a greater quantity of spirit is called ariva". The fresh koumiss they call soumal, the old koumiss. The Kalmucks call it tchigan, and others araca, but koumiss is the Tartar name for the fermented mare's milk. The fresh mare's milk is called by the Kalmucks *jouven-ousjou*, and the fresh cow's milk *oukiren-ousjou*. In their tents, where they live, they distil a spirit from koumiss, which they keep all the year round in stock. They usually keep their mare's milk in a bag made of horse's hide undressed, which, by being smoked, acquires a degree of hardness. Its shape is conical, somewhat triangular, from being composed of three different pieces, set in a circular base of the same hide. The sutures, which are made with tendons, are secured with a covering on the outside, with a doubling of the same skin, very closely fastened. It has a rather dirty appearance and disagreeable smell. These leathern bags they use both for the preparation and transport of koumiss on their vans. They usually cover these bags with a woollen cloth, a thick rag, or a large sock, but so that the stick at the lower end (made in a manner of a churn-staff, and used for agitating the vinous liquor) may be in sight and at hand. In some parts, they transport it on the backs of camels, supposing that the continuous agitation gives a better flavour and stronger taste to the koumiss, which they spare for particular occasions, as weddings, for the entertainment of good old friends, etc., where old koumiss is of greater value, being more advanced in fermentation, stronger, and more exhilarating.

The best koumiss is manufactured in the government of Osenberg, especially on the large estate of Testeleff, in the village of Kilimow, in the district of Beleber. In the government of Stavropol, Taurien, and on the Caucasus, the koumiss is not so well prepared, and has an unpleasant effluvia of horse perspiration, as even the best sorts of koumiss prepared from mare's milk always have more or less, but to which patients soon grow accustomed.

I have myself seen many formulæ for making koumiss from cow's milk or ass's and goat's milk, but I think that, since the koumiss is so well prepared in London by Messrs. Edwin Chapman and Co., we should use their preparations with all the confidence which, according to my own experience and that expressed by many members in your valuable *JOURNAL*, their various preparations merit. There is no doubt that particularly their medicine koumiss answers well in cases of gastric catarrh, vomiting, bronchitis, consumption, albuminuria, etc.; and the patients usually like it at once, or get soon accustomed to its prolonged use, if necessary.—I beg to enclose my card, and remain, dear sir, yours obediently,  
April 1878.

MEDICUS.

**MENSTRUATION AND THE CURING OF MEAT.**

SIR,—I thought the fact was so generally known to every housewife and cook, that meat would spoil if salted at the menstrual period, that I am surprised to see so many letters on the subject in the *JOURNAL*. If I am not mistaken, the question was mooted many years ago in the periodicals. It is undoubtedly the fact, that meat will be tainted if cured by women at the catamenial period. Perhaps the fact is not so generally known, that meat cured by men suffering from gonorrhoea or syphilis will also be spoilt. Whatever the *rationale* may be, I can speak positively as to the fact.—Your obedient servant,  
Wm. STORY.

Linslade, April 8th, 1878.

D. M. R.—Fairlie Clarke on *Diseases of the Tongue*, and Morell Mackenzie on the *Use of the Laryngoscope*.

**MUSCÆ VOLITANTES.**

SIR,—I have been for some time a sufferer from what are called *muscæ volitantes*, and having read several authors on the subject, and performed many experiments on myself, I beg to offer you the following explanation of their origin. *Muscæ volitantes* appear to occur only in weak eyes, or those which water freely from long gazing at any object. They pass slowly downwards over the field of vision, and disappear until the eyes are blinked, when they once more appear and vanish as before. They occur on standing at some luminous object, as a window. My theory is, that they are caused by molecules of conjunctival secretion, slowly gliding over the anterior surface of the cornea, becoming renewed upon the surface of the membrane at each closure of the lids in the act of winking. Does not their circular and watery appearance justify this supposition? If you will kindly give this publicity in your columns, perhaps some of your many readers may suggest a remedy for this distressing affection.—I am, sir, your obedient servant,  
F. K. GREENWOOD, M.R.C.S.

St. Bartholomew's Hospital, April 15th, 1878.

MR. E. MATTHEWS (Redhill).—We have no information on the subject.

**MR. HUMEROTHY AGAIN.**

IN reference to this gentleman's letter in the *Standard* of April 6th, on the subject of compulsory vaccination, we beg leave to refer to a paragraph in *Punch* of April 13th, which runs as follows: "Shall we deal with fools according to their folly, or bray them in the mortar of penal law, whether their folly depart from them or not under the braying? Such is the question raised on Mr. Pease's Bill for limiting the cumulative penalties under the Vaccination Act. Mr. W. E. Forster and Mr. Gladstone in favour of second reading of the Bill; Lord R. Churchill, Mr. Playfair, and Mr. *Punch* against, and the Bill thrown out—as it deserved to be—by 271 to 82. Fools cannot be allowed to perpetuate and disseminate small-pox. The only amendment of the law Mr. *Punch* would sanction would be one authorising compulsory vaccination of children, where parents had neglected to protect their little ones from the one plague against which science has reared an impregnable barrier, behind which—though many from ignorance and carelessness neglect it—only fools that are fanatics, and fanatics who are fools, obstinately refuse to shelter. Consideration to them is cruel and wrong to their children. And to prevent this the law *must* take order."

NEMO (Torquay).—A memorandum on the subject of the construction and arrangement of temporary fever or epidemic hospitals has been prepared and issued by the Medical Officer of the Local Government Board, from whom copies may be obtained on application.

**NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**

The following were the questions on Anatomy and Physiology submitted to the candidates at the written examination on March 29th, when they were required to answer at least four (including one of the first two) out of the six questions. 1. Describe an act of respiration, and the changes which the blood and air undergo. 2. Describe the mucous membrane of the dorsum of the tongue. 3. Describe the ethmoid bone and its articulations. 4. Describe the scalenus anticus muscle, its attachments and relations. 5. Describe the course, relations, and branches of the anterior tibial artery from its origin to the ankle-joint. 6. Describe the dissection required to expose the trunk of the musculo-spiral nerve. Give its branches and their distribution.

The following were the questions on Surgical Anatomy and the Principles and Practice of Surgery submitted to the candidates for the membership at the written examination on April 12th, when they were required to answer at least four (including one of the first two) out of the six questions. 1. Describe the axillary artery, its course and relations. Supposing this vessel to be ligatured in its third part, how would the collateral circulation in the arm be carried on? 2. What are the differences between the coverings and relations of an oblique and a direct inguinal hernia? What are the risks attending the operation for strangulated bowel in either case? and how would you avoid them? 3. Describe the disease usually called fistula lacrymalis, its causes, and the treatment to be adopted for its relief. 4. Describe and explain the symptoms of fracture of the spine, with compression of the cord, in the middle dorsal region. How would you treat such a case? 5. What do you understand by the healing of a wound by the "first intention"? what by the "second intention"? Describe the nature of the process in each case. 6. What is a hæmatocele? under what circumstances may it occur? Give the treatment you would adopt immediately, or in a chronic case.

The following were the questions on the Principles and Practice of Medicine. 1. Describe the symptoms, course, and sequelæ of diphtheria, and state the treatment you would adopt in the various stages. 2. What are the pathological conditions leading to hemiplegia? State the prominent differences in the symptoms according to the locality of the lesion. 3. Give a list, and the average doses for the adult, of the vegetable and saline purgatives contained in the *Pharmacopœia*, specifying their various modes of action. Write out a prescription in full for a single draught.

**CERTIFYING FACTORY SURGEONS.**

SIR,—You will much oblige me by publishing in the *BRITISH MEDICAL JOURNAL* this correspondence, as I believe that it throws light on a subject of importance to certifying factory surgeons.—Your obliged,  
HERBERT M. MORGAN.

Lichfield, April 11th, 1878.

Wolverhampton, April 6th, 1878.

"Dear Sir,—The Lichfield Brewery Company have applied to me respecting a charge you have made for examining three boys, for which you have charged 2s. 6d., in addition to 6d. for each boy. A short time ago, a resolution was passed by the chief inspector, that in places where there were never more than five persons under the age of sixteen, these might be taken to the surgeon's house and examined there for 6d. each, without the 2s. 6d., which is to be paid when the certifying surgeon goes to the factory. I am afraid that I have omitted to explain this to you before. Personally, I prefer that the certifying surgeon should go to the factory; but as the regulation exists, persons who come under it have a right to avail themselves of it.—I have told the Brewery Company that it is my fault for not explaining it to you.—I am, yours truly, G. S. L. BLEKINSOPP.—Dr. Morgan."

Lichfield, April 5th, 1878.

"Dear Sir,—I beg to thank you for your courteous letter, informing me of an alteration in the fees payable to certifying factory surgeons, of which I was in total ignorance. If I have your meaning correctly, the present regulation is as follows. An employer, who has not more than five young persons on his premises, may send one of them to me to be examined for a medical certificate of health, for which examination and certificate he tenders me the handsome fee of *sixpence*. I hope that I am mistaken, and that no such insult to the medical profession has been authorised by the chief inspectors; but if such be the case, I must ask you to at once accept my resignation of the post of certifying factory surgeon for Lichfield, and to notify the same to the proper authority. I reserve the right to publish this and your reply in the medical papers.—Yours faithfully, HERBERT M. MORGAN.—G. Blekinsopp, Esq."

Wolverhampton, April 9th.

"My dear Sir,—In reply to your note, I enclose you a memorandum issued by the inspectors in 1871. As far as has come to my knowledge, very few have availed themselves of the sixpenny fee, owing to the trouble of taking the persons to be examined, or of sending some one with them, to the house of the certifying surgeon. As regards your resignation, I should be glad if you would defer it till I have an opportunity of seeing you, though, if you desire it, I will forward your letter to Mr. Redgrave.—Yours faithfully, G. S. L. BLEKINSOPP.—H. M. Morgan, Esq."

Lichfield, April 10th, 1878.

"Dear Sir,—I am much obliged to you for your note and enclosed printed memorandum. I must ask you to accept my resignation forthwith, as I cannot submit to receive sixpenny fees; at the same time, I will continue to act for you for the next month or so until you can make fresh arrangements with another surgeon, so that you may not be put to inconvenience by my sudden resignation; but I shall dismiss the sixpenny cases after certifying without asking any fee. In conclusion, let me thank you for placing a disagreeable communication in as pleasant a form as you could personally.—Yours faithfully, HERBERT M. MORGAN.—G. Blekinsopp."

**HEADACHES.**

SIR,—In reply to an inquiry from Brighton as to how headaches, supposed to arise from the overstimulating quality of the air, should be treated, a correspondent from Liverpool advised giving up stimulating food and drink, including tea. Now, I find that when the air is overstimulating from dryness, weak tea has a tendency to induce skin-moisture, and to relieve the heart and the head, while coffee and cocoa are more suitable to moisten weather; and this seems to agree with the indications of national taste. The inhabitants of the dry regions of Central China, and Russia, drink tea. In the moister climates of Italy and France, cocoa and chocolate are preferred. In the medium climate of Germany, coffee largely prevails. We observe, too, that the tea-plant grows in upland districts away from the sea, coffee at a moderate height not far from the coast, cocoa in low shore districts and islands.

There seems to be some connecting link of suitability between the food produced by a climate and the natives thereof, or of similar places. I have no doubt much of our English taste for tea arises from the artificial house-climate produced by carpets and fires.—Yours faithfully,  
Jo. C.

## MATERIA MEDICA EXAMINATIONS.

SIR,—I fear lest the discussion upon this subject should die away, leaving us still doubtful how much of botanic and pharmaceutical detail may safely be omitted from our teaching. Dr. Farquharson's letter was generously conceived in the interests of the students; but the interests of the lecturers themselves may furnish arguments for reform also. They can scarcely lecture with energy upon matters which they, in common with their hearers, consider really valueless. May I, therefore, attempt, if no one else will do so, to revive the question, What shall materia medica lecturers teach? Perhaps if it were desired of any one that he should propound a general theory of examinations, he would say that they should test the capacity of a man for doing the work he proposed to do by actual observation of how he did it. This plan is now partially followed in the clinical and practical work expected of candidates in medicine and surgery. It may be reasonably extended to materia medica. In his future career, the medical man may even yet find it necessary—at least occasionally—to dispense medicines himself. He must, of course, know how to prescribe them; and he must, as far as possible, know what change each drug is capable of effecting, in varying quantities, in any or all of the body-tissues. It is unnecessary to point out how a practical examination based upon these requirements should be conducted, further than to suggest that in those parts of the examination which are representative of life circumstances, in which books will usually be at hand, and in which instant action, and, therefore, ever present knowledge is not required, books of reference may be consulted by the candidate, the object being to find whether he will be able to do his work under these very conditions. And inasmuch as the examination is, on the present hypothesis, to represent the actual requirements of practice, not less nor more, the candidate should not be expected to remember now what he will not need to remember hereafter; nor, on the other hand, should he be allowed to pass if he forget now what it is essential he should always remember hereafter. What medical man knows to what "natural order" nuxvomica belongs, or of what avail has this memory been to him? Concerning the extrication of strychnia, the same may be inquired; but the appearance, the precise action, the dose, the purity, and the chemical and physiological compatibilities of strychnia are relations of it with which the brain of every student should be deeply impressed; and there is little doubt that the concomitant introduction of almost useless relations deadens the impressions that it is so desirable these other relations should make upon him.

To take an example from the inorganic series of drugs—iodide of potassium—it would be a relief to both teachers and learners to neglect its mode of preparation, and to attend only to those of its qualities or properties which are of positive moment to therapeutists and prescribers. And why should they not? For no other reason than that the students may possibly be asked, at an examination a question demanding knowledge upon that point. To whom shall we appeal? What examining bodies, what individual examiners, will plainly tell us that henceforth we may leave the general chemical knowledge which such questions involve to be dealt with in the chemistry lectures and papers? We surely do not suppose that students can keep these things long in their minds: it is enough if they have ever comprehended the general principles of chemical science upon which such details are based. Now that therapeutic science has such vastly greater proportions than formerly, when text-books on materia medica contained very little else than applied chemistry and botany, these latter must yield in place as they do in practical importance. The time has come for reform: why should it be for another day delayed?—I am, sir, your obedient servant, T. CHURTON, M.D.

Leeds, April 1878.

MR. M. M. BRADLEY may have observed that a similar communication in somewhat more detail had been earlier received from Dr. Duffey, and was published.

MR. R. ERYDEN (Uffculme).—The notice was inserted at page 551 of the JOURNAL for April 13th.

## DIALYSED IRON.

SIR,—I should not have troubled you with any reply to Messrs. von Glehn and Sons' remarks on my observations on dialysed iron, were it not that they contain a curious blunder, to which I might be supposed to assent if I were silent. They say "nitrogenous food is colloid, but it is absorbed none the less; and the hydrated oxide of iron cannot, therefore, fail to be at once acted upon by the acid of the gastric juice and rendered capable of absorption." Is it possible that Messrs. von Glehn think that the iron is converted into a peptone? I can attach no other meaning to their remarks; but such a view is really too ridiculous to need discussion. The dialysed iron is incapable of absorption as a solution; but as, on dilution with ordinary water, it all becomes precipitated in gelatinous flocculi, it no doubt is in this condition in the stomach. If the "London Physician's" experience have led him to think this a good form of administration, it is in direct contradiction to that of other physicians in and out of London.—I am, sir, your obedient servant, JOHN CAVAFY.

THE following communications have been handed to the General Manager:—Dr. W. R. Hughes, Liverpool; Commander Blount, London; Dr. H. Donkin, London; Mr. Henry G. James, Beverley; Dr. J. W. Moore, Dublin; Dr. C. B. Ball, Blaenavon; Dr. R. Bowles, Folkestone.

## A PECULIAR CASE.

SIR,—I should be obliged if you would give publicity to the enclosed observations, soliciting from your numerous readers any remark which might tend to elucidate the diagnosis and treatment of this peculiar case.

A. C., a boy aged 10, born of healthy parents, had no disease up to the age of nine. He then had a slight attack of gastritis, which was cured in ten days. He always was and is of a lively disposition, is intelligent, and in every respect healthy. About a year ago, on returning from school, he had an attack of hicough, which lasted for a few minutes, and repeated three or four times a day. This lasted for two or three months; after which, the hicough was replaced by a peculiar cough, which also lasted for two or three minutes each time, was repeated three or four times a day, and also lasted two or three months. At this time the cough was replaced by bleating like a sheep, which symptom he has had until now. He bleats on rising in the morning, takes a shower-bath and bleats again, has breakfast and bleats twice until one o'clock, then again at 6 P.M.; after which he stops until the next morning, continuing every day, and at the same hours more or less. He sleeps well, and immediately after the attacks is as merry and well as any other child. This is the information given by the father, who is a very intelligent man. I was asked to see the boy to-day for the first time. On going upstairs, I heard him bleat three times. This was the end of an attack: immediately afterwards, he came and spoke to me as if nothing had happened. He speaks with a hoarse voice, evidently from the effects of the bleating. In answer to my questions, he told me he knew when the attack was coming, but could not help it. He runs away to the back of the house, where he is least heard, and begins. He is perfectly conscious, can walk about during the attack, and has no convulsion or fit of any kind. Several medicines have been tried, to no purpose. Sea-baths during

four months at the seaside reduced the bleating to once a day, and then lasted about half a minute instead of two or three. During this time his hoarseness almost disappeared.

I heard of a similar case in a young girl a few years ago, whom I did not see, but whom I heard whining and barking like a young dog. I was told that these attacks came on at intervals of five or six hours, between which she was quite well.—I am, etc., SEMPER VIGILANS (Member).

March 30th, 1878.

## MIDWIFERY ENGAGEMENTS.

SIR,—I should be glad if you or some of the members of the Association would give your opinions on the point of engagements to attend in midwifery. I have seen the point discussed several times, but cannot recollect that any settled decision was arrived at, as to whether, if a medical man were engaged to attend a woman in her confinement and not sent for at the time, he had a right to claim his fee or not. I know that some county court judges will order the fee to be paid, but the uncertainty of the law is proverbial. It has happened to me three or four times lately to have been engaged to attend and then not to be sent for at the time, and I have not been certain what I ought to do about claiming the fee. I did claim half the fee from a man to-day, and he flatly refused to pay it, so I would be glad to have some advice on the matter. I know that a great many women engage a doctor to attend them in their confinement, and do not mean to send for him unless it turns out to be a difficult case, and then they refuse to pay any extra fee, so I am very strongly of opinion that every woman that engages a doctor to attend in her confinement ought to be made pay the fee whether she sends for him or not.—I remain, sir, yours obediently, ROBERT E. BURGESS, M.D.

Frankton-on-Severn, Gloucester, April 13th, 1878.

DR. GILLES (Runlet).—Squire's *Conpanion to the Pharmacopœia* would suit best.

## PLUGGING THE NOSTRILS.

SIR,—Mr. F. Davison seems to have misunderstood my suggestion respecting plugging the nostrils, for I fully appreciate the value of Bellocq's cannula, as well as that of his old pensioners the gum elastic catheters. I think, however, that Mr. Davison will find, as I stated, that the soft or worm-catheter is much easier of introduction and more expeditious than either of the others. Mr. Davison must have been fortunate in meeting with cases of epistaxis requiring only one plug. I have had difficulty after using two, even when aided by iron, tannin, and ergot as adjuncts.—I beg to remain, sir, yours very faithfully, T. T. FRANKLAND.

Ripon, April 10th, 1878.

ENQUIRER.—The degree of M.D. may be obtained without residence, by a duly qualified practitioner (such as M.R.C.S. Eng. and L.S.A.), from the Universities of Durham, St. Andrew's, or Brussels, under conditions which may be obtained from the authorities of those institutions. Our correspondent will also find the conditions on which the two British Universities above named grant the degree in the Educational Number of the BRITISH MEDICAL JOURNAL (September 8th, 1877); and those relating to the University of Brussels in communications from correspondents in various numbers of the JOURNAL.

## A MEDICAL CHRONOGRAPH.

SIR,—In the JOURNAL of April 6th, a watchmaker inquires whether "a watch so constructed as to beat audibly in unison with the average healthy pulse . . . and having a hand describing the full circle of the dial . . . would be considered an advantage?" For obvious reasons, there would be no advantage in such an arrangement. There would, however, be an advantage in what I am about to suggest. Let quarters of minutes only be marked by audible sounds. A watch so constructed would not only enable the medical man to count the pulse in the dark, but it would also allow him to pay greater attention to its quality while in the act of counting than is possible for him when under the necessity of closely observing the watch-dial at the same time. Matters might be arranged so that the sounding apparatus could be thrown into and out of gear at will.—I am, etc., ARTHUR LEARED, M.D.

April 1878.

ARTHUR LEARED, M.D.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fifehire Herald; The Merthyr Express; The Camarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

COMMUNICATIONS, LETTERS, etc., have been received from:—

OF

## A CASE OF ABNORMAL DISPOSITION TO SLEEP, ALTERNATED WITH CHOREIC MOVEMENTS.\*

By W. T. GAIRDNER, M.D.,

Professor of Medicine in the University of Glasgow.

In August 1875, I reported to the Medical Section of this Association, then meeting in Edinburgh, a "case of abnormal disposition to sleep, alternated with choreic movements", which communication was afterwards published at length in the BRITISH MEDICAL JOURNAL for October 30th, 1875, page 547. At page 229 of the same volume appears a brief abstract of the case, with some remarks by Dr. Clouston. In recording the case in detail, especially as regards the history, I was aided by copious notes based on information obtained for me by the ordinary medical attendant, whose name and locality were, however, for certain reasons partly stated at the time, and still more pressing now, purposely suppressed. The case was generally regarded as extremely interesting, if not almost unique, in its associated phenomena; the only ones nearly resembling it which came to my knowledge being one of which I had private notice by Dr. Clifford Allbutt, and the one briefly alluded to by Dr. Clouston in his remarks. In surveying the details of history and symptoms as a whole, it was impossible to avoid the analogy with chorea as respects the motor phenomena; but the psychical features of the case were extremely baffling, and did not fit in with the described or personally observed characters either of catalepsy, ecstasy, lethargy, hysteric coma, or mesmeric hypnotism; the distinctions from all of these being more or less elaborately traced in the paper referred to. To the question that naturally occurred, Is this girl a malingerer? a negative answer was returned, on the double ground of want of apparent motive, on the one hand, and disability, on the other. It was held that "anything like premeditated deception or scheming, acted out consistently for so long a period as in this case, would imply powers as well as motives for deception which seem to be wholly absent". I am not ashamed of this conclusion as emerging from the facts then known to me, however much it may be brought into doubt by some that I have now to relate.

An apparently unsophisticated girl, living in strict retirement with her two aunts, visited by and visiting no one; menstruating regularly, and "subject to no known cause of hysterical derangement"; enjoying (apart from her peculiar symptoms) fair bodily health, "cheerful and even lively, presenting no trace of exaggerated self-consciousness, and no dramatic or imitative faculty"; having no religious or metaphysical prepossessions, and never having "been in any way made an exhibition of, either in public or in private":—such were the conditions apparently presented to our view in 1875.

I confess that I fail to see even now what motive could have been devised or suggested adequate to sustain the hypothesis of a long course of deliberate and most consummate acting, extending over three whole years continuously, and never for one moment departed from in sleep or waking, or amid any of the more ordinary incidents of an uneventful life, so far as to permit a well founded suspicion of imposture or a detected incongruity. Yet that the impulse to deceive existed, we now know too well from the sequel presently to be recorded. At what precise point conscious deception came to be superadded to abnormal action of the mind and motor centres, I believe we do not now, possibly we never can, know. But I think we may easily draw one conclusion from the whole case, and it is this, which, I think, gives the sequel of it so great, if so sad, an interest for us in the Psychological Section. Surround this simple and unemotional girl with the early impressions and the religious machinery, so to speak, of the Roman Catholic Church; accredit her with a quasi-miraculous mission; let her feel in its strongest form the unwholesome excitement begotten of crowds of unreasoning votaries; and then let her be initiated into the moral code which counts all things admirable and praise-

worthy which are done from overwhelming religious emotion—a *maiorum Dei gloriam*—give these conditions, and you have the elements as complete as could be desired for a history like that of Louise Lateau. Introduce her, with proper preparation, into a mesmeric circle, and you have the "Eliza" of Dr. Gregory, the famous clairvoyante hand-maiden of Miss Martineau, the Okeys of Dr. Elliotson. Through what process of change for the worse the transition from a physically diseased to a morally depraved nature is accomplished, it is often hard to say; but here we have the basis, the raw material, so to speak, of such accomplished and skilled performers as those I have mentioned presented in its most elementary form; something which bears the same relation to them as do the crudest and commonest of spirit-rapping marvels in the present day to the matured and oft-repeated feats of the best trained "mediums", or the capital imitations of these by Messrs. Maskelyne and Cooke. And, in writing these words, I am reminded that it would be morally impossible for my tongue to utter them, or for my pen to note them down, were it not for the practical certainty that they can do no harm to the subject of my present narrative. I share, in regard to her case, the conviction expressed in regard to it by one of the ablest specialists of my acquaintance, presently to be quoted, viz., that physical disease laid the foundation upon which the superstructure of attempted deception was built up. The object of this sequel to her case is not to judge or to condemn, but to furnish materials for science and for the practice of the medical art.

At the time when I first saw her, M. T. had been about two years subject to the peculiar interrupted somnolence and to the chorea-like movements described in the former narrative. At the time of the paper read to the Association in 1875, she was eighteen years of age, and had passed three of these years in abrupt transitions from a state of (apparently) dreamless and motionless sleep of the most profound character to waking moments characterised invariably and constantly by the peculiar motor phenomena described at length in the paper. On looking over the case now, with the increased knowledge since obtained of it, I find nothing to modify in the statement of the facts so far as they came under my own observation. The head-shakings, the agitations of the features and limbs as described, were totally distinct from the familiar ones of the hysteric, epileptic, or any other general convulsion; they were also "quite distinct from the tremor of paralysis agitans or of mercurial poisoning", and "wholly devoid of any dramatic character or apparent significance". The sheer tedium and monotony of the business, one would think, would have worn out the patience of a malingerer more effectually than any severities practised could have done in the way of cure or of detection. Fancy a deliberate scheme of imposture, whose only resources were to go about shaking the head, twitching the left side of the face, and jerking the right arm during every single waking moment for years together, in season and out of season, the only relief obtained being, momentarily, when the attention was strongly roused, and more completely, indeed usually completely, during sleep. Add to this that the falling into and coming out of sleep were almost instantaneous, and never varied in their character or in the absolute naturalness of their expression, and you have in summary the case as presented in 1875. Some of the incidents might, indeed, be open to doubt, and were at the time mentally discounted as possibly the result of imperfect observation; e.g., the eight days' sleep on one occasion without taking food or spontaneous evacuations. But this rested wholly on the testimony of her aunts, not even on her own (as she seemed to be wholly unconscious of it); in fact, I never once heard her spontaneously refer to any of the more striking facts of her own case, nor did she appear at all anxious to talk about them, or in any way whatever to obtrude them on our notice.

About a year after my first communication was written, I received the following interesting letter from Dr. —, the ordinary medical attendant, who first brought M. T.'s case under my notice.

July 12th. 1876.

"Dear Dr. Gairdner,—I intended calling on you long ago to tell you about our interesting patient at —, but somehow never had time.

"For some time after you saw her, there was very little change in her symptoms, except that she began to lose appetite and to get weaker, so that she did not care to move about so much, or go out to the garden, as she was accustomed to do. You remember, when you saw her, she had an eruption on her forehead something like erysipelas; this continued for four or five months, more or less; it would heal up for a day or so, then appear again in the form of large vesicles or bullæ, which would burst, heal up, and appear again in regular succession.

"After this had appeared on her forehead for a month, the back of her right hand became similarly affected, and it gradually spread up the arm to a little above the elbow. The arm is still affected, but

\* Read in the Section of Psychology at the Annual Meeting of the British Medical Association in Manchester, August 1877.

the brow has been free for the last three months. It is a kind of pemphigus. Another peculiar feature, which I have never before seen, is a peculiar discoloration which appeared under both eyes about four months ago. At first, it had only a dusky colour, such as is usually seen in a person who is sick or bilious; but gradually it became darker until now it is quite black, like a negro's skin; it is not like ecchymosis, but is more like a deposition of pigmentary matter. A slight degree of it is sometimes seen over both cheeks. Her appetite has been gradually leaving her for the last six months, and, within the last three months, she has not been able to retain her food; no sooner does she swallow it than she puts it up; it is more a regurgitation than a vomiting, as far as I can make out, for I have never seen her put up her food; but her aunt tells me that, whatever food she is forced to take (for now it is a matter of compulsion), it has hardly time to be down when it is put up. She has retained no food for a fortnight, and I really cannot understand how she possibly survives.

"But the most remarkable phenomenon which is now presented by this most extraordinary case is her breathing. Two months ago, I noticed that she breathed in a spasmodic manner; there was no difficulty in the expiration; but there seemed to be a spasm of the glottis which prevented inspiration. She had to wait some seconds till the spasm gave way before she could inspire. She said 'she could not breathe when she willed', but could only take a breath when the spasm relaxed. This is now constant and more marked; she can only articulate a word during expiration, and has to wait for relaxation of the spasm before she can articulate the next word. Again, every second or third day, usually in the evening, she has an attack of extreme spasm of the glottis, producing something like laryngismus stridulus. Unfortunately, I have not seen her in any of these paroxysms; but her aunt tells me that to witness it is dreadful. She seems fighting for breath; her eyes stare; she clutches at anything, and seems on the point of suffocation, when suddenly the spasm relaxes, and there is a loud crowing inspiration, which is so loud as to be heard outside, and this goes on for two, and sometimes three, hours, when it gradually relaxes and she falls asleep. This paroxysm has begun during sleep, and she has had to be awakened to prevent suffocation. She does not fall asleep so frequently as she did. I do not expect she can live many days, and thought that, as you were interested in her case, you, perhaps, would like to see her; but it must be soon."

On receiving this letter, I made a visit to the patient without any previous notice to her, and almost the first glance at the externally visible facts of the case assured me, not only of the accuracy of Dr. —'s description of these, but that an element had become apparent which, although to a professional eye easily enough detected, required to be warily approached, and (as regards the relatives at least) very delicately handled. I sat down by her bedside and asked a few ordinary questions, in presence of her aunts, about the appetite and digestion, general strength, rejection of food, and so forth. It was evident that no ideas had entered into the minds of her nearest relatives and constant attendants as to any voluntarily induced phenomena, or any volitional control over those now or previously existing. I took care not to disturb this feeling by any unguarded expression, and framed all my inquiries so as to elicit from the patient herself, if possible, what she could and what she could not do. Yet it was evident, on a very brief inspection, not only that the head-shaking and chorea-like symptoms were to a great degree controlled, but that the new symptoms connected with the respiration above described were of the order generally familiar to medical men as hysterical, and, in point of fact, largely controlled by the will. I then approached the subject of the pigmentary deposit around the eyelids. "Can it not be washed off?" I asked, as if doubtful on the point. No one had ever tried to wash it off. "Give me a bit of clean white linen rag." This was brought. I tore it up, took a small strip, and deliberately wiped off the black marks from one of the eyes, amid some manifestations of shrinking, as though from tenderness of the skin. "Oh; I will not hurt you at all; you see I am very careful, but you see also it comes off quite freely. You can keep it quite clean if you like." This was a new discovery to the aunts, obviously. "Now, let us try the other side. Another piece of rag, if you please; for I want to see exactly what this colour is, and how soon it will come back. The skin is quite clean now, and here is all the colour on this rag. There is no broken surface at all there." By this time, I was morally certain of the fact that the pigment was nothing else than carbon externally applied; but it was agreed that we should make this doubly sure by a microscopic and chemical examination of the soilings on the portions of rag which I took away with me. I expressed to her aunts the belief that it would be necessary to place her under the care of a physician specially skilled in strange nervous disorders, and so the interview closed, as I intended, without any suspicions expressed on either side, though perhaps not without an unex-

pressed feeling on the part of the patient that she was suspected. Two days afterwards, I returned with Dr. Vellowlees, and the remainder of the history may be told in his very striking and pathetic words, it being understood that, in the interval, a careful examination had proved to demonstration—1. That the pigment was mere carbon in a fine state of division; 2. That it was mixed, but not organically incorporated, with the microscopic elements of the epidermis. These facts were ascertained for me by Mr. Ferguson, Professor of Chemistry in the University.

"Dear Dr. Gairdner,—I find it impossible to report in the ordinary manner the history of Miss T., while she was under my care; for the treatment was so entirely moral in character, and so directly personal in its administration, that the first personal pronoun recurs with offensive frequency. I prefer, therefore, to put it in the form of a letter, where 'I' may seem less obtrusive, or may at least be better tolerated than in a more formal record.

"When I first saw her in consultation with you and Dr. —, she was a very pretty but fragile girl, and her face had a strange weird look from the blackening of the suborbital areas. Her head was in constant motion (partial rotation) while she answered your questions, which she did intelligently, though in a scarcely audible voice. Conscious that she was being watched by the stranger you had brought with you, her face flushed; she looked at me with a fixed gaze of inquiry and apprehension, and then there gradually came on one of her usual 'fits'.\* The movements of the head became greater, the eyes rolled, the breathing was embarrassed and gasping, and there were irregular jerking movements of the limbs and of the whole body. These symptoms continued for several minutes, then gradually subsided, the patient passing into what looked like a calm deep sleep, in which, it was said, she would continue for hours, and from which she could be awakened only by shouting her name into her ear. During the seizure, her friends were much distressed, and expressed the most anxious solicitude on her behalf.

"After the sleep had continued for some time, she was aroused by the usual method, other ordinary means having been tried in vain. She awoke with a slight start, looked bewildered for a few moments, then seemed as if she had suddenly remembered our presence, and immediately answered questions as calmly and correctly as before. Some dark pigment was removed from under the eyes by wiping the surface firmly.

"I believed the nervous disturbance to be entirely functional, or what we call 'hysterical', for want of a better name, and recommended, as the first and indispensable step, that she should be removed from her home and from too sympathetic friends to new surroundings, and to the care of nurses accustomed to such cases. When assured that this would be the first step towards recovery, she readily consented to reside under my care, and Dr. — brought her to her new abode. On arrival, the pallor of her countenance was so great as to be manifestly artificial, the shaking of the head was constant, and one of the 'fits' very soon occurred. There could be no doubt as to the character of this fit. The gradual beginning, the very safe and easy way in which she slid from her chair to the floor, the brevity of the fit when two seemingly indifferent doctors were the only witnesses, and the ease with which she was roused from the subsequent sleep, were very significant. Not less so was a special message sent by her through the doctor about forwarding a dress of a particular colour which she had omitted to bring.

"For some days, little was done beyond observing her symptoms and gaining her confidence. Constant movement of the head, even when she might have thought herself unobserved, frequent fits, extreme loathing of food, vomiting after every meal, frequent short cough, and occasionally jerky spasmodic breathing, were the chief symptoms. The fits occurred twice or thrice daily, and she was extremely thin and weak.

"The discovery of some tooth-powder carefully wrapped by itself explained her deadly pallor on arrival, which, of course, ablation had satisfactorily removed. The right forearm was covered with a thick dry cake of what seemed to be old eczematous exudation; its removal by poulticing revealed an almost healthy surface, and restored the use of an arm which she thought beyond cure.

"When observation had been continued long enough, and a suitable opportunity seemed to have arrived, I bade the nurse stand by the door, assumed as much quiet decision in tone and manner as I could, and had a conversation with her like the following.

"I have told you that you will get better, but you cannot believe it. I am going to prove it to you to-day. I wish to tell you some-

\* These "fits" differed considerably from anything observed when I first saw the patient, and especially in their affecting the respiration. See Dr. —'s letter, quote above.—W. T. G.

thing which will show you that I perfectly understand your illness, and will enable you to believe what I say. Those dark circles under your eyes were painted by yourself.' A start and an instant denial. 'Do not repeat that denial, please; I *know* it. You got some black stuff and rubbed it on.' More denials, but with flushed face and conscious look. 'I *know* it as well as if I had seen you. I will prove to you that I know it. Your paleness on the day you came here was only tooth-powder which you had rubbed on your face.' No denials now, but a startled look, tearful eyes, and helpless silence. 'I do not tell you this to hurt your feelings, nor to give you pain, neither do I need to tell your friends about it; but I wish to show you that there is no mystery in your case.' The conviction was complete, and her confession was unreserved. She told me that she had darkened her eyes with the lead from her pencil, and that she had done it because her friends thought it denoted biliousness, and so did not insist on her taking food, to which she had extreme repugnance, on account of the sickness and vomiting which eating produced. She declared her intention to tell her kind friends all about it as soon as she was well, and was anxious to know if you knew all.

"This was the right mood, so, of course, I went on with as much quiet emphasis as possible. 'You know from this that I understand your case, and now I tell you that you can perfectly control your other ailments; that the fits, the shaking of the head, and the vomiting must cease. They are not needful; they prevent you from getting well. You have the power to stop them, and I wish you to do so.' She promised to try, and, of course, she succeeded in all but the cough, which unhappily was more than nervous. Within a fortnight, I was able to report to Dr. — in these words: 'No preternatural sleep, no choreic movements, no shaking of the head, no vomiting, no fits; up and out every day.' The persistence of the cough was unfortunately due to lung-disease. When made aware of this, her friends took her home again, and she died a few months afterwards.

"I trouble you with no comments; but it is due to the memory of our most interesting patient to express my full belief that her attempts at deception did not result from moral obliquity, but were as purely the product of disease as the abnormal sleep and the eccentric movements. — Yours very faithfully, D. YELLOWLEES.  
"To Professor Gairdner."

It seems only necessary to add to this impressive narrative a very few lines. I never saw M. T. again. Her anxiety to be informed if I were a party to Dr. Yellowlees's profound insight into her case remains, so far as I am concerned, unsatisfied. No word of reproach was ever uttered to her or about her by any of her medical advisers; and to this hour, I believe, her relatives remain in ignorance of the strange revelations that took place when she was in the hands of strangers, and the marvellous effect of a few words, faithfully and firmly spoken, in rousing the latent healthy instincts of a "mind diseased". Had this poor girl lived in an age when demoniacal possession, or witchcraft, or the "evil eye" remained a part of the popular creed, her disease and her cure, if published abroad, could scarcely have escaped one or another of these interpretations. As it was, she died an ordinary death from phthisical exhaustion, and her death-bed was undisturbed either by superstitious fears or by any unusual manifestations of moral emotion. The only remark she made to her faithful and attentive ordinary medical adviser which could, however remotely, bear the construction of a kind of half-guilty self-consciousness, was that she had been "very foolish". And I think, on the whole, that no humane judge familiar with the secrets of what has been recently called "spiritual pathology", certainly no skilled medical judge, looking at the facts of her sad case from the medico-psychological point of view, would be inclined to condemn her in any harsher terms than these. This simple narrative, impersonal and without lengthened commentary, will prepare for us all that is needful of an experience fraught with inexpressible human interest, though the subject of it, seeking neither praise nor blame, remains for us but the shade of a shade.

CRICKHOWELL.—The death-rate in this district was 22.4 per 1,000 in the year 1877, and of children under one year 3.96 per 1,000 inhabitants. This death-rate is considered very favourable by Mr. Hill, who also especially notices the small mortality from zymotic diseases, although measles prevailed during the summer to a considerable extent. Only one case of small-pox occurred; and, as the patient exposed himself in a public place, he was summoned and convicted. The rest of the community escaped, as Mr. Hill believes, from the re-vaccination of a large number of inhabitants. The want of proper sleeping accommodation is especially mentioned, as well as the imperfect water-supply and overcrowded state of the churchyard.

## CLINICAL LECTURES

ON

### THE VARIETIES OF PHTHISIS.

*Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.*

By C. THEODORE WILLIAMS, M.A., M.D., F.R.C.P.,  
Physician to the Hospital.

#### LECTURE IV.—FIBROID PHTHISIS.

GENTLEMEN,—In our last lecture, we considered the form of phthisis arising from catarrhal pneumonia, of which the principal features were alveolar epithelial proliferation, leading to caseation, irritation of the alveolar wall, and consequent tuberculosis, progressive consolidation, and excavation. We now turn to a very different group of patients, in most of whom the phthisical disease may be traced to inflammation attacking the pleura and interlobular tissue, and thence reaching the parenchyma. Here we have interstitial pneumonia, as it is called, as the basis of the disease, instead of catarrhal pneumonia; and its development and after-changes give rise to the very important features which mark the fibroid variety of consumption. The principal pathological element is fibrosis, which, while it is present to a greater or less extent in most cases of chronic phthisis, is the most important feature in fibroid phthisis, and its preponderance and effect on the lungs and circulation largely influence the history of the patients of this group.

By the term fibroid phthisis I would signify cases of phthisis in which fibrosis is the main feature; and therefore I do not enter on the question of its being primary or secondary, though it is for the most part secondary in instances I have seen. Fibroid phthisis, then, would include all that Dr. Andrew Clark intended when he communicated his admirable paper to the Clinical Society, and, in addition, cases where tuberculosis has supervened. There are two principal modes of origin: firstly, from attacks of pleurisy and pleuropneumonia; secondly, from chronic pneumonia resulting from long-continued irritation of the lungs through the inhalation of various kinds of dust or grit, such as prevails among fork-and-knife-grinders, colliers, and buttonmakers. The history of symptoms in the first group may be sketched as follows. A patient has an attack of pleurisy with effusion, from which he recovers with absorption of fluid; but percussion shows dulness over the whole side and somewhat feeble respiration. The patient recovers, but experiences dragging pains in the side; a dry hacking cough, somewhat paroxysmal in character, with little expectoration; and the breathing, always short, becomes still more so on exertion. There is emaciation, and often night-sweats. These symptoms increase; and a few months later we find marked immobility of the affected side, still dulness throughout, and now considerable shrinking; the circumference of this side, whether taken at the level of the second rib, or of the nipple, or of the ensiform cartilage, measuring one or two inches less than the healthy side. On auscultation, we notice the breathing to be very deficient in some parts, and in others bronchial and sometimes cavernous in character; but generally there is everywhere absence of true vesicular breathing. Careful percussion of the opposite side of the chest shows the line of resonance to extend beyond the usual limit, passing to the edge of the sternum, and often an inch or two farther, demonstrating that the contraction of the affected lung has caused the healthy one to be drawn across in order to fill up the void. Other organs are likewise displaced. If the left lung be affected, the heart is tilted, not necessarily upwards, as where a cavity is contracting, but outwards. The stomach rises, its note being audible as high as the fourth rib. The heart is not only displaced, but is uncovered by the retreating lung; and the right auricle and ventricle are clearly distinguished by their pulsations, while the right lung is drawn across to the left side to the extent of one or two inches. If the right lung be affected, the left may be drawn over; and the area of resonance may extend as far as the inner half of the right clavicle, and the line drawn thence sloping towards the middle of the sternum. The heart is transposed, and its impulse may be traced in the fourth interspace on the right side. The liver rises up to the fifth rib, and shrinking of the chest-wall takes place as on the other side. In these patients, the pulse is generally slow, and the temperature seldom rises above the normal, and is often subnormal. When the temperature rises over 100 deg. Fahr., it signifies that something besides fibrosis is going on. The cough is troublesome, and often induces vomiting; and the expectoration becomes more and more difficult, and in time, on account of retention, foetid. Meanwhile the dyspnoea increases, the other lung

becoming involved; signs of obstructed circulation appear; dropsy of the extremities takes place, and rapidly increases; the urine becomes albuminous and of low specific gravity; and the patient dies either of dyspnoea or of blood-poisoning, his death contrasting strongly with the ordinary termination of consumptive disease. After death, we find a lung contracted to the size of a man's fist, with enormously thickened and adherent pleura and widely dilated bronchi, with interlobular septa much increased in size and encroaching on the lung-structure, which seems to be replaced by a hard fibrous tissue, mottled with grey in parts, deeply pigmented, and resembling cartilage in its resistance to the knife. Embedded in this structure are found caseous and cretaceous masses, or, again, excavations of various sizes; the walls of these and of the dilated bronchi being rigid and inelastic from the presence of the fibroid material, and thus affording some explanation of the difficult expectoration and consequently troublesome cough. Besides these changes, we may find the other lung the seat of tuberculosis, though this is not necessary; but commonly the bronchial glands are hardened and deeply pigmented. There is often amyloid disease of the liver and spleen, and frequently a granular condition of the kidneys.

Such is fibroid phthisis; but we must bear in mind that its principal element—*fibrosis*—is brought about by interstitial pneumonia arising from (1) unresolved croupous pneumonia, or (2) from the irritation of the alveoli by hard particles, as in colliers' phthisis, or (3) from pleurisy. We find a large development of fibroid tissue, causing a thickening of the alveolar walls, and afterwards filling up and obliterating the alveolar spaces themselves; and besides this, there is an enormous increase of the interlobular connective tissue in all its various ramifications, and especially in the parts surrounding the large vessels and bronchi as they pass to the lobules.

The microscope tells us that the growth is either fibro-nucleated or densely fibrous, and presents the characters of cicatricial or scar-tissue. But, though this fibrosis is apparently the same in whatever part of the lung it may occur, it is not so in reality; for Dr. Green has shown that, while the fibrosis of the interlobular septa does not caseate and break down into cavities, that of the alveolar growth does, because the former is amply supplied with blood-vessels, and the latter is destitute of them; and this gives us an important means of distinguishing between the two.

It is needless to say that cases of fibroid phthisis differ widely, according to the amount of lung involved, the presence of cavities, the state of the bronchial tubes, and the amount of elastic lung available, which materially influence the symptoms. We will now consider a typical case.

Isabella C., a married woman aged 29, a dressmaker, was admitted under my care April 18th, 1871, and gave the following history. She had lost a cousin on her mother's side from consumption. For three years she had had cough and expectoration, and about two years ago noticed that she was emaciating. Hemoptysis to the extent of four ounces came on soon after the beginning of the illness, and to the same amount three months later; and again, after two months, in February 1869, two ounces were coughed up, but none since then. She had had night-sweats, which ceased before admission; and she once for two weeks suffered from diarrhoea. Latterly she had complained of increasing shortness of breath, which had become very troublesome. In September 1869, she became an out-patient under Dr. Douglas Powell, who found flattening, dulness, and cavernous breathing in the upper right chest anteriorly, and tubular respiration and moist crepitation over the posterior base. He observed that the left lung was enlarged, and extended to the right of the sternum; and he detected crepitation at the apex and along the posterior surface. Dr. Powell's diagnosis was a cavity in and contractile disease of the right lung, and granulations in the left. In October 1869, she was admitted into the hospital under Dr. Cotton, when the right lung was found to be in the same condition; but in the left harsh blowing respiration had taken the place of the humid crepitus. She remained in the hospital for three months, taking phosphated oil alternately with quinine and other bitters, and gained seven pounds and a half in weight, the physical signs remaining the same. After this, she continued better for some time; but the symptoms returned, and her increasing shortness of breath caused her to apply to the hospital, where she was admitted under my care in April 1871. Her cough was very troublesome; expectoration frothy; tongue clean; bowels regular; catamenia absent for two years; great emaciation, especially of the thorax. The right side of the chest was considerably smaller than the left, the shoulders greatly depressed, and the upper portion of the chest fixed. Marked depression was visible in the upper right front as low as the third rib, this space being decidedly resonant. Cavernous breathing was heard under the clavicle, though chiefly below the sternal end. From the

fifth rib downward, there was absence of breathing and marked dulness, not removable by change of position. Posteriorly, cavernous breathing was audible in the right inter- and supra-scapular regions. The heart's sounds were more audible over the lower portion of the sternum than in the cardiac region, and the apex could not be felt. It was, therefore, concluded that the heart was displaced towards the contracted side. The diagnosis was contractile or fibroid disease of the right lung, with some excavation of the upper portion, and displacement of the left lung, liver, and heart towards the affected side. The patient was ordered cod-liver oil and quinine, but she did not improve; and on April 27th the evening temperature, which had been normal, rose to 100 deg. Fahr.; and three days later the morning temperature rose to 101 deg. Fahr., and then remained between 100 and 101.6 deg. Fahr., with the exception of one day, till May 4th. The patient became weaker, and the breath shorter. Sonorous rhonchus and harsh breathing were audible in the left lung. On May 15th, the morning temperature fell to 98.4 deg. Fahr., and the evening to 99 deg. Fahr.; the pulse being 100, respirations 40. After this, the morning and evening temperatures varied between 98 and 98.5 deg. Fahr.; and on May 20th the breath became very difficult, crepitation being audible at the base of the left lung. Dyspnoea increased, and the patient died on the 25th.

The *post mortem* examination was made by my then clinical assistant, Mr. William Rose, in the presence of Dr. Powell and myself; and the following account is taken from our notes.

The body was greatly emaciated. There was marked concavity from the right clavicle to the second rib, and general shrinking of the whole right side of the chest. On removing the cartilages, the right lung could not be distinguished at first, but was afterwards found contracted to a third of its normal size, occupying the axillary and lateral regions, and not extending lower than the fifth rib. The heart was drawn over to the right side of the sternum, the apex being slightly to the left of the ensiform cartilage. The liver, which was much enlarged, was drawn up, and, owing to the retraction of the right lung, had become superficial below the fifth rib; it did not extend far below the margin of the ribs. The left lung stretched across the median line as far as the costo-sternal articulations on the right side, this being the case as low as the third rib. The right lung, weighing 20½ ounces, was universally adherent to the chest-wall; the pleura, with intervening adhesions, being on an average half an inch thick, and thickest over the diaphragm, where it contained in its interior a great deal of fibro-gelatinous material. The texture of the lung itself was dark grey, traversed by whitish fibrous bands proceeding from the pleura, interlobular septa, bronchi, and vascular sheaths. In the upper lobe were the remains of an old cavity into which some bronchial tubes opened, their mucous membrane seeming to terminate at its entrance. The cavity appeared to have undergone contraction, and was divided by numerous fibroid septa stretching across it, separating it into smooth-walled loculi which communicated with each other. The left lung was much enlarged and congested, the edges being highly emphysematous. It contained some cheesy nodules, around which were miliary tubercles of recent date. In the portion drawn over to the right side was a small cavity of the size of a walnut, which corresponded to the area of the cavernous respiration heard under the right clavicle. The heart was large; the right ventricle slightly dilated; valves healthy. The liver and spleen were both lardaceous; kidneys healthy.

In this case, the shrinking of the right lung had caused a void, which atmospheric pressure had filled in various ways. The chest-wall was contracted; the liver pressed upwards the heart to the right of the sternum, and the upper part of the lung into the right chest. Owing to the portion of the left lung containing a cavity, it gave rise to cavernous sounds under the right clavicle, from which it was naturally concluded that the cavity existed in the *right lung*, whereas—strange anomaly—it really was in the *left lung*, though in the right chest. The portion of the lung would doubtless during respiration have reached further to the right side, and thus given rise to cavernous sounds over a larger area of the right chest than appeared in the *post mortem* examination. The fact of the remains of an old cavity in the right lung might explain the cavernous sounds heard by Drs. Cotton and Powell at an earlier period; and it might be suggested that these physicians listened to the sounds in a different cavity from the one I directed my attention to; but this is improbable, from the fact that Dr. Powell even then detected the presence of the left lung to the right of the sternum; and this displacement would hardly have occurred without a retraction of the right lung, including its excavated upper lobe, to the axillary and lateral regions of the chest, where, if anywhere, the cavernous sounds from this source would have been audible. The condition of the pleura indicated that the disease originated in an attack of pleurisy, and that the contractile tissue had slowly extended

since, gradually obliterating the lung and giving rise to increasing dyspnoea. Death was probably caused by the congestion of, and eruption of miliary tubercle in, the left lung, by which the remaining breathing surface was further reduced in extent. The rise of temperature between April 27th and May 4th was undoubtedly due to the tuberculosis. The case may be considered a typical one of fibroid phthisis; the dyspnoea and the changes in the shape of the thorax being very well marked, and the life-history and *post mortem* record filling up almost every link in the evidence.

I have notes of a somewhat similar case, where the left lung was the seat of fibroid phthisis, and caused a remarkable amount of displacement of the neighbouring structures. In this patient, the left side measured two inches in circumference less than the right; the spine was curved, the convexity being towards the right; the left shoulder was depressed; and the physical signs denoted an old cavity at the apex of the left lung, and nearly entire absence of breathing over the rest of the side. The right lung was drawn halfway across the left chest, the heart's apex tilted to the left, and the stomach raised as high as the fifth rib. The right lung was healthy. The patient died from abscess of the brain, and *post mortem* examination exactly confirmed the diagnosis of the state of the lungs indicated by the physical signs. The left lung contained a small cavity at the apex, and consisted of a hard fibroid mass, impermeable to air, and occupying hardly a third of its proper area, the rest of the space being filled up by the encroachments of the adjoining organs, as had been described during life. This patient lived four or five years from the date of the first symptoms, and might have lived much longer but for the cerebral disease, which seemed quite unconnected with the pulmonary lesions.

The *prognosis* depends on the amount of lung involved in the fibrosis, and on the rate of its contraction. Where half a lung, or at the most one whole lung, is permeated by alveolar fibrosis, and where this process is limited by the white bands of interlobular tissue—where, in fact, matters remain at a standstill—there the patient may live for years, provided he limits his exertions in proportion to his breathing powers, and does not place himself under circumstances to induce a fresh inflammatory attack or necrobiosis in the old fibrotic lesion. The patients who trace their disease to pleurisy seem to have the best chance of life, for their cases last longer than those arising from pure interstitial pneumonia. I have records of two cases, one lasting ten years and the other fifteen, each of which commenced in pleurisy. In both of these, excavation took place; but their health remained tolerably good until the opposite lung was attacked. In other instances, fibrosis has proceeded rapidly, permeating the whole lung, and, by obstructing the vessels, inducing dilatation of the right side of the heart and dropsy of the abdomen and lower extremities, the kidneys usually becoming affected towards the close of life. It is remarkable how general the rule appears to be that, when fibrosis predominates over the other morbid processes, the life-history of the case becomes at once changed; the typical consumptive character is lost; obstruction to the respiration and circulation, with accompanying dyspnoea and dropsy, close the scene, contrasting sharply with the termination of catarrhal phthisis or scrofulous pneumonia. It will be seen that the prognosis, therefore, depends on the amount of lung involved. Fibrosis saves one patient; it saves another by limiting the area of consumptive disease, and thus preventing fresh absorption and tuberculosis.

*Treatment.*—Our objects in the treatment of fibroid phthisis are—first, to limit the area of disease, and to prevent any fresh portion of the lungs becoming involved either by fibrosis or by inflammation; secondly, to maintain, or possibly to raise, the standard of nutrition in the patient, and thus obviate any tendency to necrobiosis in the fibroid material. The patient must avoid all great exertions, which lead to lung-congestion, and should live in an equable atmosphere, to guard against fresh catarrh or pneumonia. The dry warm climate of the Riviera, or, again, the still drier one of Upper Egypt, have been found most useful for this purpose; and many of these cases have lived on for years by wintering in these localities. The improvement of the nutrition must be attempted by the usual antiphthisical treatment, such as cod-liver oil, strychnia, the mineral acids and bitters, and plenty of easily assimilated food. The preparations of iodine have been recommended as likely to promote absorption of the fibroid material and counteract the advance of fibrosis; but in my hands neither these nor any other drugs have sufficed for this purpose, though I have seen great improvement take place in the general condition from steady perseverance in the use of the hypophosphites of soda, lime, or iron, and even of the less powerful phosphates and dilute phosphoric acid. The local inflammations of the pleura and lung are best combated by counter-irritation with blisters or strong iodine liniments, and by promoting free expectoration. Where cavities or dilated bronchi exist, it is not uncommon to find foetid sputum, adding still more to the irritation, and

only evacuated by fits of coughing which close with vomiting. Here the stimulant expectorants, such as compound tincture of benzoin, tolu, and turpentine, are the most likely to relieve; while much may be done by antiseptic and stimulant inhalations of tar, creasote, carbolic acid, and thymol. The increasing dyspnoea and cardiac asthenia can be temporarily relieved by spirit of ether, by carbonate of ammonia; and the dropsy by purgatives and diuretics; but, if the obstruction in the lung have reached this point, we cannot hope for more than a temporary improvement by any medical aid.

## PATHOLOGICAL ILLUSTRATIONS OF THE LOCALISATION OF THE MOTOR FUNCTIONS OF THE BRAIN.\*

By RINGROSE ATKINS, M.A., M.D.,

Resident Medical Superintendent District Lunatic Asylum, Waterford; late Assistant Medical Officer District Lunatic Asylum, Cork; etc.

THE object of the following communication is to record several cases which have come under my observation illustrating the localisation of cerebral disease, and tending, I believe, to show that the facts elicited by experimental research have a direct applicability to human pathology.

The experiments of Hitzig, Ferrier, Nothnagel, Schiff, Carville, Duret, and many others, are now universally known; and, although many varying explanations have been advanced by different schools of physiologists to account for the phenomena, yet, in the main, the broad fact that stimulation of certain regions of the cerebral cortex is followed by definite movements has been established on a firm basis. The results of these experiments have shown that, in the convolutions bounding the fissure of Rolando in man and those surrounding the crucial sulcus in the dog, cat, etc., there is a zone, the excitation of which causes movements on the opposite side of the body, and the destruction of which causes disorders of voluntary motion, or even persistent paralysis, while in regions closely related to these no such effects are produced. Since these facts became known, their application to human pathology has been a matter of the deepest interest and importance. Dr. Hughlings Jackson, from whom, if I may so speak, the "doctrine of localisation" took its inception, has recorded many cases illustrating the effects of localised lesions of the cortex in the production of definite symptoms varying in extent according to the position of these lesions; the recent annals of the various French scientific societies abound with similar records, and the almost daily observations of M. Charcot and his pupils at the Salpêtrière tend universally in the same direction. In addition, the histological researches of Betz, verified by those of Mierzejewski, give a kind of anatomical confirmation to these results by showing that, in the vicinity of the fissure of Rolando, and particularly in the paracentral lobule (the internal free surface of the ascending frontal and ascending parietal convolutions in the great longitudinal fissure), there exist large pyramidal cells similar to those of the anterior cornua of the spinal cord. As the result of his extended pathological observations, M. Charcot has now mapped out on the cortex of the human brain regions, destructive lesions of which cause paralysis more or less extensive, according to the extent of surface affected. These regions closely correspond to those mapped experimentally by Ferrier on the monkey's brain; and, in order to illustrate this clearly, I here exhibit a prepared hemisphere of the human brain in which the so-called *motor zone* is coloured black, while the non-motor region is white, the individual convolutions being indicated by different coloured discs lettered to correspond to this index. From this preparation, it can be seen that the motor zone includes the ascending frontal and ascending parietal convolutions (anterior and posterior central of Ecker), the posterior terminations of the three frontal, the anterior edge of the postero-parietal (superior parietal lobule, Ecker), and that of the inferior parietal lobule. The non-motor zone comprises the anterior portions of the three frontal convolutions, the posterior parts of the postero-parietal and inferior parietal lobules, the three occipital and three temporo-sphenoidal convolutions, together with those at the base of the brain and the island of Reil. Of course, between these two regions, there can be no hard and fast pathological line of demarcation drawn, the motor region insensibly blending into the non-motor and extending probably in one brain farther than in another, according, it may be, to the size and configuration of the individual convolutions.

The cases I am now about to relate are illustrations of lesions occurring in the non-motor and motor regions, and they tend, I believe, to

\* Read in the Section of Psychology at the Annual Meeting of the British Medical Association in Manchester, August 1877.

support M. Charcot's views, that in man lesions within the motor zone are accompanied by motor disturbance, while lesions in the non-motor areas produce no such symptoms. Taking first the non-motor region, the three following cases afford examples.

**CASE I. *Glio-sarcomatous Tumour of the Left Temporo-sphenoidal Lobe: Softening of Middle Portions of Superior Middle and Inferior Temporo-sphenoidal Convolutions; Circumscribed Hemorrhages into Softened Tissue: no Motor Symptoms.***—N. C., female, aged 80, died on March 25th, 1876. She had been an inmate of the asylum for many years, suffering from quiet dementia. She continued in good health up to a short time before her death, and to the last possessed normal power over the limbs and various muscular groups, for a few days previously being somewhat dull and lethargic, but sinking gradually without any further symptoms becoming apparent. On removing the scalp, a bulging was observed on the surface of the left parietal bone, near its lower border. The calvarium was thinned and with difficulty removed, owing to its inseparable adhesion to the dura mater. On forcibly removing the bone, the latter membrane was seen to be almost incorporated with it, so firm were the adhesions; and attached to the inner surface of the parietal, inferiorly, was a flattened tumour as large as a small apple, growing from the lateral surface of the left temporo-sphenoidal lobe, about the centre of its superior and middle tier of convolutions. This tumour was incorporated with the brain-substance, and was soft and of a reddish-grey colour. Subsequent microscopical examination showed it to be glio-sarcomatous in its nature, consisting of numerous widely dilated thin-walled vessels and masses of round ovoid and elongated cells closely aggregated, without any appearance of intercellular substance. These cells contained granular nuclei, and varied in size, some being as small as the nuclei of the neuroglia, while others were as large as those found in sarcomata occurring elsewhere. The groups of cells appeared to be arranged concentrically around the vessels, and interspersed amongst them were many large sized round cells (giant-cells). On the separation of this tumour, a softened cavity was disclosed deep in the substance of the temporo-sphenoidal lobe, as large as a good-sized walnut, and containing whitish curdy matter. The brain-tissue around this cavity was broken down, and above it were found two fresh circumscribed globular blood-clots as large as hazel-nuts. The pia mater generally was anæmic, and contained clear fluid beneath it; ramifying in it were very beautiful congeries of tortuous vessels filled with blood, closely resembling injected Malpighian bodies in the kidney. The membrane stripped easily, and the convolutions beneath were wasted and separated by broad and shallow sulci, but presented no further localised lesions. A section through the centrum ovale showed the brain-substance to be anæmic; an oval patch of a reddish colour blending with the surrounding tissue existed in the posterior part external to the posterior cornu of the lateral ventricle. The lateral ventricles, opto-striate bodies, and basal ganglia were normal in appearance. The arteries at the base of the brain were atheromatous in patches. Microscopical examination of the grey matter from the frontal parietal and occipital convolutions showed the larger nerve-cells to be in the second and third stages of pigmentary degeneration.

On this chart of the hemisphere (fig. 1), I have indicated the external

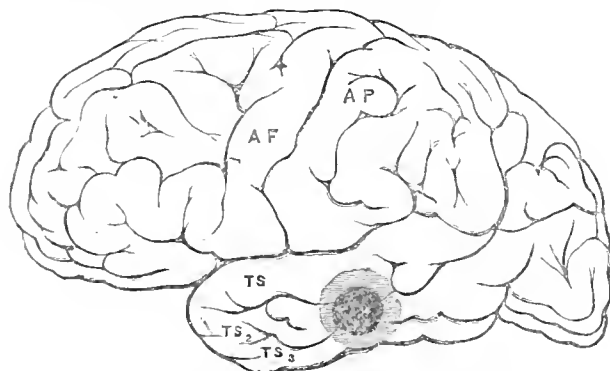

Fig. 1. —Glio-Sarcomatous Tumour of Left Temporo-Sphenoidal Lobe; Softening of Middle Portions of Superior Middle and Inferior Convolutions; Circumscribed Hemorrhages into Softened Tissues.

site of the tumour by a black disc, while the zone of softening around it has been coloured yellow. From this, then, it can be seen that the lesions were strictly confined to the temporo-sphenoidal lobe, and, though they originated in a morbid growth, regarding which great

caution must be exercised, from the fact that such growths may displace tissues without destroying them, and thus produce indefinite phenomena, yet, from the isolated position of the tumour here, being separated from the remainder of the hemisphere by the Sylvian fissure, and from the fact that, though it did lead to destroying lesions of the adjacent brain-substance, no motor symptoms appeared, I think the case may be made use of for the purposes of this study.

**CASE II. *Localised Deposit of Lymph on Dura Mater over Posterior Portion of Postero-Parietal Lobule of Left Hemisphere; Adhesion of Membranes; Superficial Erosion of Cortex: no Motor Disturbance.***—P. S., male, aged 66, died on September 9th, 1876, of diarrhoea. This patient had been an inmate of the asylum since April 1868, suffering from chronic dementia. Beyond the dullness and hebetude consequent on his mental condition, he presented no symptoms calling for special note; there were no motor disturbances, the man being able to move about freely until he became affected with the diarrhoea to which he eventually succumbed. On *post mortem* examination, the calvarium was soft under the saw; about four ounces of sanious serum escaped during the removal of the brain. The dura mater was strongly adherent to the frontal bone, requiring considerable force to separate it, which was, however, done without tearing the membrane. Over the posterior portion of the postero-parietal lobule of the left hemisphere was an irregularly ovoid patch of thick and shaggy organised lymph larger than a crown-piece, forming a growth on the inner surface of the dura mater, and inseparably connected with the latter membrane; this was slightly adherent to the pia mater, and the latter to the cortex of the postero-parietal lobule, leaving, when stripped from it, a patch of superficial erosion, which I have coloured blue on this chart (fig. 2). The convolutions generally were

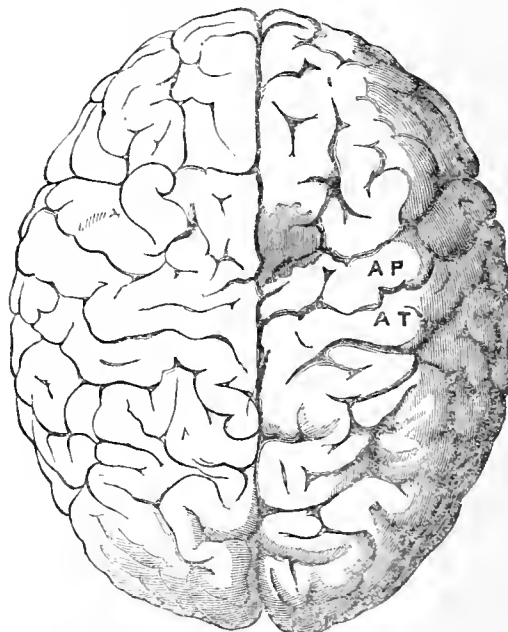

Fig. 2. —Localised Deposit of Lymph on Dura Mater over Posterior Portion of the Postero-Parietal Lobule of Left Hemisphere; Adhesion of Membranes; Superficial Erosion of Cortex.

somewhat atrophied, but no further gross lesion existed. Microscopical examination showed the nerve-cells to be affected with pigmentary degeneration.

In this case, the cortical lesion was superficial and strictly confined to the postero-parietal lobule. In several of the cases recorded or alluded to by M. Charcot, in which motor disturbances existed, this region was found affected; but other and undoubtedly motor regions were also implicated. As there were here no motor disturbances whatever, this case would seem to indicate that, when involved alone, disease of this region will not give rise to such symptoms.

**CASE III. *Softening of Gyrus Supramarginalis and Centre of Occipital Convolutions of Right Hemisphere; no Motor Disturbances of Left Side; Lesions of Left Hemisphere causing Aphasia and Right Hemiplegia.***—In this case, which I have already fully recorded elsewhere (*Journal of Mental Science*, October 1876), there were "foci" of softening occupying the gyrus supramarginalis and portions of the occi-

pital convolutions of the right hemisphere, while no motor disturbances at the left side manifested themselves, the lesions in the left hemisphere sufficiently accounting for the motor disturbances at the right side. The lesions in the right hemisphere are indicated on this chart. (Fig. 3.)

Turning now to the motor zone, the following cases are illustrations of lesions occurring there, and accompanied by motor disturbances.

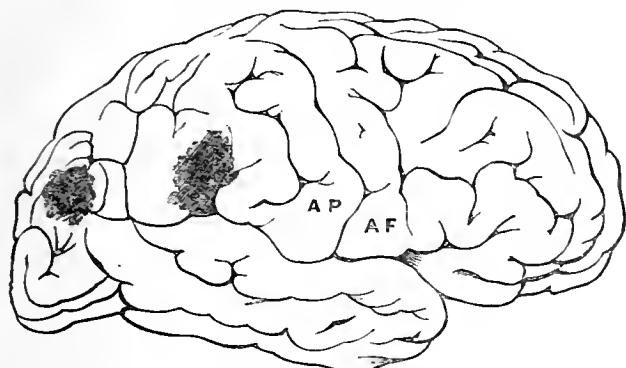

Fig. 3.—Softening of Gyrus Supramarginalis and Centre of Occipital Convolutions of Right Hemisphere.

**CASE IV. Meningeal Hæmorrhage; Pressure on Left Ascending Frontal, Ascending Parietal, and Edge of Inferior Parietal Lobule; Right Hemiplegia.**—M. N., female, aged 62, died on March 27th, 1876. She had been an inmate of the asylum for six years, suffering from chronic insanity, with periods of maniacal excitement. About a week before her death, she complained of a feeling of general weakness and undefined pains about the chest, which, however, could not be traced to any apparent cause; her appearance was florid and healthy, and, beyond some slight general weakness, she had no loss of motor power over the limbs. On March 25th, 1876, she became noisy and troublesome; and, two days afterwards, about eleven o'clock in the forenoon, while sitting quietly before the fire in the day-room, she suddenly slid off the form and became semi-unconscious. On being placed in bed, she was found to be semicomatose and paralysed on the right side, the limbs being quite flaccid. When spoken to loudly, she was able to mutter indistinctly; but did not appear to comprehend what was said; the face was cold and collapsed; the pulse slow and weak. The coma gradually deepened, and she sank in about two hours.

**Necropsy.**—The skull was asymmetrical, the right parietal eminence bulging; the calvarium was soft and easily sawn through. The dura mater was intimately adherent to the left half of the frontal bone, and was thickened and opaque, especially over the right hemisphere, where its inner surface was lined with a thin layer of gelatinous material easily scraped off with the scalpel, and probably the decolourised remains of a former hæmorrhage. The great longitudinal sinus contained a partially decolourised thready clot. The right middle meningeal artery was atheromatous, and appeared torn in several places. There was much hypostatic congestion of the vessels of the pia mater over the posterior lobes of both hemispheres. On the left hemisphere, confined to the lower half of the ascending frontal, the ascending parietal, and portion of the anterior edge of the inferior parietal lobule, a soft clot lay on the pia mater, from which it readily separated. On removing the brain, the surface of the bones forming the anterior and middle fossæ of the left half of the skull were covered with a very thin layer of recent blood-clot, which extended from the olfactory groove on the ethmoid, along the orbital plate of the frontal bone, the petrous and lower part of the squamous plate of the temporal, and the inferior and lateral surfaces of the occipital. This extravasation was in great part little more than a colouration of the osseous dura mater with blood; it was somewhat thicker at the olfactory groove, and had insinuated itself beneath the left olfactory nerve, where a small elongated coagulum was also found. This extravasation had probably been continuous with that found lying on the convolutions, and was effused from a ruptured meningeal vessel, which, however, could not be found. The convolutions generally were atrophied and diminished in consistency, especially those of the parietal lobe of the left hemisphere, where, at the junction of the gyrus angularis and gyrus supramarginalis (Ecker), a depression as large as the top of a finger existed, over which was a bulla of clear yellow fluid (fig. 4). On section, the brain-substance was anæmic; the grey matter was thinned, especially in the occipital lobes. The ventricles and commissures were normal, and the opto-striate bodies

plump and regular; the basal ganglia was healthy. The left internal carotid artery was atheromatous; the basilar and vertebrals were studded with similar patches. Microscopical examination in the recent state showed the larger ganglion-cells to be in an advanced state of pigimentary degeneration, and, in some instances, in what appeared to be a condition of calcification.

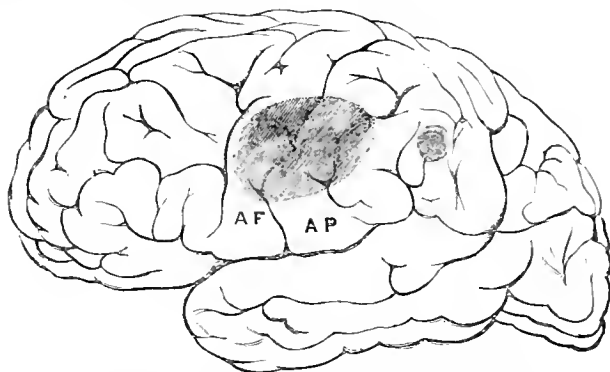

Fig. 4.—Meningeal Hæmorrhage; Pressure on Left Ascending Frontal, Left Ascending Parietal, and Edge of Inferior Parietal Lobule.

In this case, an acute apoplectic seizure occurred, the necropsy revealing recent meningeal hæmorrhage; hence there can, I think, be no doubt that this lesion and the paralysis which supervened stood to each other in the relation of cause and effect. Now, although the extravasated blood was effused over a considerable extent of surface, yet it was only on the ascending frontal and ascending parietal convolutions, and in the olfactory sulcus, that it had assumed the characters of a regular clot, and was attached to the surface of the brain; hence I think it equally certain that to the pressure or presence of the clot in this portion of the motor region the right hemiplegia was due, the extent of the paralysis and the fatal result being probably accelerated by the already weakened and degenerate condition of the nerve-centres generally, which were in consequence unable to bear up against the sudden shock.

[To be continued.]

#### SPONTANEOUS RUPTURE OF THE SPLEEN.\*

By E. MARKHAM SKERRITT, B.A., M.D.Lond.; M.R.C.P.;

Fellow of University College, London; Physician to the Bristol General Hospital; etc.

IN the following case, splenic apoplexy, and consequent rupture of the capsule of the spleen, took place under what I believe to be very rare and, perhaps, unique conditions. The case is of interest clinically, and also has a medico-legal importance to which a recent trial in India calls special attention.

The patient was a shepherd fifty-three years of age, admitted into the Bristol General Hospital on July 4th. He stated that, up to two months before admission, he had enjoyed good health; then he began to suffer from nausea and pyrosis, and entirely lost his appetite. He had done no work for six weeks. A month before admission, he had an attack of epistaxis, which lasted about twenty-four hours, during which time he lost much blood. Since this, he had noticed a sensation of beating in the upper part of the abdomen. Just before admission into the hospital, another severe attack of epistaxis came on; the patient was, however, able to walk up into the ward without help.

When I saw him next day, he was almost blanched from loss of blood, but cheerful and anxious to give all the information in his power. The heart's impulse was weak, and there was a faint systolic apæmurmur; the pulse was feeble and the vessel degenerate. The abdominal aorta was pulsating to a marked degree, but no distinct dilatation of the vessel could be made out; a systolic *bruit* was plainly heard in the vessel, but was found to be only due to pressure. There was no pain or tenderness in the abdomen.

I concluded that there was no aneurism of the aorta, and that the pulsation and *bruit* were due to the anæmic condition consequent upon the loss of blood.

Soon after 9 P.M. the same day, the patient, who up to that time had

\* Read before the Bath and Bristol Branch.

seemed no worse, was suddenly seized with great dyspnoea and symptoms of collapse, which ended in death in less than an hour.

**POST MORTEM EXAMINATION.**—There was a large quantity of dark fluid blood in the peritoneal cavity. There was no aneurism. The capsule of the spleen was greatly distended; on the anterior aspect of its peritoneal surface there was a rent an inch long, through which the finger passed into a large space full of fluid blood. At first sight, it seemed as if the enlarged spleen were split longitudinally into two halves, which were separated along their whole length by this layer of fluid blood about an inch and a half thick; it was found, however, that the capsule had been stripped off the whole peritoneal surface of the spleen by blood effused between it and this surface, and that one of the apparent halves before mentioned was simply a firm layer of dark clot, about three-quarters of an inch thick, forming a thin cake applied closely to the inner surface of the capsule, and separated from the spleen itself by the layer of fluid blood before described. The exact source of the hæmorrhage could not be found. The splenic substance was of a brick-red colour, and very soft and pulpy (there had been considerable *post mortem* change). The spleen and clot together were eight inches long, five inches and a half broad, and three inches and a half thick, and weighed twenty-six ounces. The rest of the organs were very æmic, but otherwise healthy.

**REMARKS.**—Rupture of the spleen is not a very uncommon occurrence; but almost invariably it is caused by external violence, such as blows, crushes, falls, wounds by fractured ribs. Instances have been met with, however, where the organ has ruptured spontaneously; in conditions where it is intensely congested, as in typhus, cholera, and the cold stage of ague, where it is probable that weakened texture has been combined with extreme congestion. But I have been unable to find any record of a parallel case to the one that I have related, where, at the time of the rupture, the patient was suffering from no acute disease, and had been quietly lying in bed for hours.

If we consider the state of the spleen *post mortem*, we see that the first event was hæmorrhage within the capsule, giving rise to the large clot before described, which, from its characters, must have been formed some time before the fluid blood was effused and the capsule gave way. There was the following sequence:—first, hæmorrhage between the spleen and the capsule; then cessation for a time; then more blood poured out, and in such quantity that the capsule gave way. Hence the actual rupture of the capsule was secondary and accidental.

Was there any *congestion* of the spleen as the first event? I think not; rather the opposite. The man had just been blanched by severe epistaxis, and there is no reason to suppose that the spleen would be other than anæmic, like the rest of the body. The conclusion must be that the same weakness of vessel that caused the repeated bleeding from the nose led to the hæmorrhage into this organ, especially as this occurred at a time when the force of the circulation had been much reduced by loss of blood.

I now turn to the medico-legal aspect of the case. Some months ago, a trial took place in India which excited much interest. The following short account I take from a medical periodical. "A curious medico-legal point was involved in a recent trial for manslaughter in Ceylon. A coolie was treated with some severity by the superintendent of a plantation, and died almost immediately from rupture of the spleen. The man had had fever lately; the spleen was large and soft. It was urged for the defence that the spleens of coolies sometimes rupture spontaneously on severe muscular exertion; that the exertion of running away might have ruptured the spleen; and that death would not be the direct result of the action of the accused. This theory was discountenanced by the medical witnesses, and we think rightly. An accident so rare, and *even doubtful*, as such rupture of the spleen must be, cannot be allowed weight in the presence of evidence of direct violence. The Chief Justice ruled that the rupture was distinctly the result of the violence. The prisoner was found guilty." If I remember rightly, the exact occurrences were these. The coolie received a box on the ear and fell down; he then got up, ran away, climbed over two walls, and, in so doing, fell from the top of one or both of them; he then quickly became collapsed and died. Here was plenty of muscular exertion; besides that, the fall from the wall represented a greater degree of violence than did the previous simple fall of the coolie off his feet. If the assault caused the rupture, it did so indirectly only by causing the fall; for there was no direct violence to the abdomen. And, if this were enough to produce the laceration, how much more were the muscular exertion and the accident that followed, with which the accused had nothing immediately to do! It seems to me also improbable that a man with a ruptured spleen would run away with the activity that this coolie showed.

With regard to muscular exertion as a cause of rupture of the spleen, cases illustrating this have occurred in this country; thus Sir James

Simpson refers to three cases of fatal rupture which occurred respectively during the pregnant, the parturient, and puerperal states; in each instance, after some unusual exertion. Another case is recorded in the *BRITISH MEDICAL JOURNAL* for 1874, by Mr. Atkinson of Leeds, where the accident was apparently due to violent vomiting set up by indigestible food.

The case I have related differs from all those that I have been able to find recorded in this important particular: that there was entire absence of any special muscular exertion; for the patient had, in fact, been in bed for hours before the rupture occurred. And I think that I am warranted in concluding that this instance has established the fact that rupture of the spleen may occur purely spontaneously, in the absence of any condition ordinarily associated with congestion of the organs, and apart from all external violence or special muscular exertion.

## CLINICAL MEMORANDA.

### CROUP: DIPHTHERIA: TRACHEOTOMY.

As Dr. Bowles of Folkestone has mentioned my name, among others, as holding some rather decided opinions (I hope not dogmatic ones) on the subjects specified above, perhaps he will excuse me for offering a few remarks on his very interesting cases published in the last number of the *JOURNAL*, and which I think may readily be explained in accordance with the pathological views now, as he states, fast gaining ground.

He has described three cases, two of which were fatal, tracheotomy being performed in both, but in neither of which was there any *post mortem* examination. Thus it is not absolutely certain what the disease really was; but, considering that Dr. Bowles distinctly saw the diphtheritic patches on the tonsils in each case, and that both of them died rapidly and unexpectedly, even although tracheotomy was successful, there is little doubt in my mind that the disease in both cases was diphtheria, first of the fauces and then of the larynx and trachea. His third case, which was most skillfully treated and was successful in its result, I believe to have been one of severe infantile laryngitis. It is true that Dr. Bowles says that "doubtless false membrane already existed" on the second day of the illness, but he gives no evidence of its existence; and, indeed, he distinctly states that he carefully examined the throat for false membrane on two succeeding days, and found none. It was not till ten days after the operation of tracheotomy had been performed, and after abundance of mucus and muco-pus had been discharged through the wound, that it is stated that on expiration, "false membrane was seen flapping through the wound". But as none of this false membrane ever escaped, and as the child was convalescent in two or three days afterwards, is it not possible that a part of the lining membrane of the trachea, or even of the integuments, may have presented the appearance of false membrane? It is certainly contrary to all experience that a tube of false membrane should be present in an infant's windpipe on January 20th, and that all bad symptoms should disappear and the tracheotomy-wound be closed on the 24th. The false membrane, if it existed, must have been discharged or extracted before the patient could recover.

It is by no means alleged, by those who maintain that the so-called membranous laryngitis is really laryngeal diphtheria, that ordinary laryngitis is not a dangerous disease in some instances and never requires tracheotomy. The narrowing of the glottis in young children renders laryngitis, with its complication, œdem glottidis, a very formidable malady. What is alleged is that such cases are far less serious than laryngeal diphtheria, and that in the worst of them, as is shown in Dr. Bowles's third case, the operation of tracheotomy has a much greater chance of success. There is no false membrane, and there is no specific poison; the absence of which conditions reduces laryngitis to the level of an ordinary inflammation.

R. H. SEMPLE, M.D., F.R.C.P. Lond.

### NOTE ON THE INCUBATION OF MUMPS.\*

ON November 17th, 1877, I was asked how long a lady, who had accidentally been thrown in the way of mumps three days previously, need fear lest she had contracted the disease. Never having thought about the incubation of such a slight and usually home-treated ailment, I hazarded "a fortnight"; but was annoyed eighteen days afterwards to find I was wrong in my guess. I then consulted all the books on which I could lay hands, with the following result. Medical and surgical text-books both describe parotitis; but Tanner (sixth edition), Erichsen (sixth edition), Trousseau (Sydenham Society's edition),

\* Read before the Norfolk and Norwich Medico-Chirurgical Society.

Watson (fourth edition), Bryant (first edition), Roberts, Maursell and Evanson (1842), Gregory (1828), Forsyth (1826), make no mention of the incubative period; while Gay and Harley (*Hooper's Tale Mamm*) quote a medical student who succumbed a fortnight after contact, and Ringer (*Reynolds's System of Medicine*) gives it at from eight to twenty-two days. I, therefore, venture to think my cases worth recording as carefully observed facts, though I must leave it to others to attach their proper importance to all but the first and undoubted case.

On November 14th, 1877, Miss O., aged 18, called at a house where mumps was epidemic, twenty miles from her own home, where no case existed. She did not enter, but spoke to and nursed a child then complaining of stiffness about the jaws, and who had evident parotid swelling the next day. She returned home; was exposed to no fresh case, and was considering herself safe, when, on December 5th, twenty-one days after, she had a severe attack. No quarantine was enforced; but it was not until December 29th, or twenty-four days after this, that the next case occurred. Then, on January 16th, twenty-nine days after his return from school with a clean bill of health, and consequent entry into an infected neighbourhood, a third case occurred in the person of a brother aged 10. From this date, the cases occurred too irregularly to be of any value for my purpose, and I abandoned the investigation.

ALAN REEVE MANBY, M.R.C.S. Eng., East Rudham.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN AND IRELAND.

#### MANCHESTER ROYAL INFIRMARY.

##### LARGE AXILLARY ANEURISM, CURED BY DIGITAL COMPRESSION.

(Under the care of Mr. LUND.)

FOR the following report we are indebted to Henry Tomkins, M.D., Senior House-Surgeon.

A. L., a widow, aged 60, was admitted into the Manchester Infirmary on March 4th, 1878, under the care of Mr. Lund, with a large aneurism of the right axillary artery. The history she gave of it was as follows. About twelve months ago, she was engaged in washing some clothes, when she was suddenly seized with a sharp stinging pain, which appeared to strike down the right arm, followed by tingling and numbness of the limb, which soon became cold, somewhat livid in colour, and swollen. It was immediately rubbed gently, and wrapped up in flannel. The next morning, the numbness and pain had gone, and the arm had recovered its natural warmth, but was still considerably swollen. In the course of some little time, the swelling also disappeared without her seeking any medical aid; and with the exception of much loss of power in it, she noticed nothing particularly wrong until July, when she accidentally discovered a swelling under the clavicle and also in the axilla, but did not observe any pulsation in it. During the past three or four months, the arm had gradually become weaker and painful on movement. Six weeks ago, she had an attack of bronchitis; and it was not until her medical attendant was examining her chest for this, that she had any idea of the serious nature of her injury. He explained it to her, and at once ordered her to keep perfectly at rest in bed, limited her diet, and gave her large doses of iodide of potassium. Pressure was also attempted to be used by means of bags of shot applied to the subclavian artery.

On admission, a large swelling was observable immediately beneath the right clavicle, two inches in breadth, extending beneath the pectoral muscles in the course of the axillary artery, and projecting about an inch and a half into the axilla; it was soft, with strong expansile pulsation, the pulsation being at once arrested by pressure on the subclavian artery; a loud *bruit* was heard on auscultation. Movement of the arm caused considerable pain; the radial pulse on the affected side was fully as strong as that in the left arm; and there was no marked difference exhibited in the tracings obtained by the sphygmograph from the two sides. The patient, a spare woman, was in fairly good health; had never had any serious illness; there was no history or evidence of syphilis. The left carotid artery appeared somewhat dilated, but not to any such extent as to warrant the term aneurismal. The other arteries of the body were apparently normal, nor were there any signs of calcification in them. There was no arcus senilis. It was decided to attempt a cure by means of digital compression; and for this object, four of Mr. Lund's dressers volunteered for service. At

2 P.M. on the day of admission, compression of the subclavian artery by means of the thumb was commenced and kept up continuously until 12 o'clock midnight; this the patient bore without much inconvenience, complaining only of some slight soreness at the seat of pressure and a little numbness of the arm. At the end of this time, there was not much appreciable difference in the condition of the aneurism; it was if anything rather firmer, the swelling not feeling quite so soft, but the pulsation was still strongly marked, and the radial pulse beat apparently as fully as before. The digital compression being discontinued, it was attempted to control the circulation through the night by means of a conical bag of shot resting upon the subclavian artery; this, however, only partially effected that object. A quarter of a grain of morphia was administered subcutaneously.

March 5th.—The aneurism was decidedly firmer, and the radial pulse, although distinct, was much weaker. This also was well shown by the sphygmograph. The patient was kept strictly on Tuffnell's diet; and ten-grain doses of iodide of potassium were administered thrice daily.

March 6th.—Digital compression was again commenced at 1.30 P.M. and continued until 9 P.M. At the end of this time, the pulsation was considerably diminished in the aneurism, its expansile character having quite disappeared; the radial pulse was also very feeble. The patient complained much of soreness at the spot where pressure was applied; the limb was also very numb. A quarter of a grain of morphia was given subcutaneously, and the shot-bags were reapplied.

March 7th.—The aneurism this morning was completely solidified; not a trace of pulsation could be detected either in it or in the radial pulse. The arm was quite warm. She complained of nothing but numbness.

From this time, the patient was kept perfectly at rest on the above treatment until the 20th; the arm was then allowed to be used a little, and she was permitted to get up, she herself feeling perfectly well. She was discharged on March 24th quite cured, the tumour having decreased in size and become quite firm, and all trace of pulsation having disappeared in both it and the radial and ulnar arteries.

#### ST. VINCENT'S HOSPITAL, DUBLIN.

##### CASES OF DISEASES OF THE KNEE.

(Under the care of Dr. MAPOTHER.)

CASE I.—Edward Kane, aged 32, groom, was admitted on September 4th, 1877, for disease of the left knee, at the request of a practitioner who thought excision advisable. Acute pain, starting of the limb, and loss of sleep, had tormented him for over two months. The joint was found to be greatly flexed, and exquisitely tender; but there was little swelling, the bones and cartilages being the structures evidently affected. The limb, placed on an angular splint, was gradually extended, and blisters were freely applied in front. Five grains of blue pill and two of opium were given every night. Salivation began on the seventeenth day, with complete relief from pain; and the same treatment was kept up for a fortnight. For two months subsequently, he was given iodide of potassium internally, and the knee was strapped with mercury and ammoniacum plaster spread on leather. On February 1st, 1878, he was discharged with scarcely any stiffness remaining.

CASE II.—Ellen Kelly, aged 13, was admitted on January 18th for disease of the left knee, which had begun seven weeks before. There was some evidence of a strumous taint. The joint was slightly flexed, not painful, but greatly swelled by thickening of the synovial membrane, and effusion into its cavity. Different spots were alternately blistered, and salivation was produced with the protiodide of mercury on the tenth day. During the fourth and fifth days of the treatment, strapping with mercury and ammoniacum plaster was employed; and she left hospital on February 27th, without a trace of disease.

The above cases illustrate the use of mercury in various articular affections—a mode of treatment introduced by O'Beirne (*Surgical Society of Ireland*, 1834, and vol. v of *Dublin Journal of Medical Sciences*).

CASE III.—Mary Kearnan, aged 8, was admitted on December 13th, 1877. The right hip and knee were flexed to the utmost, and any attempt at motion was excessively painful. The left carpal bursa, as well as that over the olecranon, and several of the phalangeal joints, were tender and swollen. All these sites had been attacked eight months before, sharp fever coexisting. The case was believed to be one of rheumatic gout, notwithstanding the age of the patient and the absence of hereditary predisposition. The patient having been chloroformed, the hip and knee were extended, great force being needed and much cracking being heard and felt during the operation. The joints

were kept straight along a Liston's splint. Full doses of iodide of potassium, citrate of lithia, and cod-liver oil were prescribed. After ten weeks, the case was discharged, the limb being straight and painless, but considerably stiff at both the joints.

CASE IV.—Thomas O'Neill, aged 45, labourer, was admitted on December 14th, 1877. For three months, he had suffered from pain and stiffness in the right knee, but swelling only began three weeks before. The limb presented a most peculiar aspect. From the inner surface of the head of the tibia, a tumour, as large as an orange but more conical, projected. It was firm and slightly elastic, save at one point of the size of a pea, where fluid evidently existed. The skin was purplish, and the superficial veins distended. For five or six inches above the inner condyle of the femur, another tumour extended; but being covered by muscle, its characters were ill-defined. The patella was pushed outward, but was movable, and there was no effusion into the joint. Severe pain was endured, especially at night. A few days after admission, the skin ulcerated over the soft point alluded to, and free hæmorrhage ensued, which was checked by pressure and turpentine. The case now appeared very like one of encephaloid disease, the more so as the glands at the saphenic opening were enlarged; but that it was tubercular caries of a rapid form, soon became evident by profuse suppuration and the disintegration of the cancellous tissue in the epiphyses of the femur and tibia. Amputation was urged, but persistently refused by the patient and his relatives. He died on March 18th, 1878, from exhaustion.

An unusual bursal tumour has just been admitted, the patient being a woman, aged 72. Starting from the sac behind the ligament of the patella, it pushed that bone outwards, projected over the inner and back part of the joint, and attained the size of a cocoa nut. A seton was passed through it, and the progress of the case so far has been satisfactory.

#### ULSTER EYE, EAR, AND THROAT HOSPITAL.

EXTRACTION OF STEEL AND IRON FROM THE EYE BY THE MAGNET.

(By W. A. McKEOWN, M.D., Surgeon to the Hospital.)

THE following cases will doubtless be of interest taken in conjunction with that recently brought before the Clinical Society of London by Mr. McHardy.

CASE I.—Dawson B., aged 24, smith's helper, applied to me at the Hospital on January 16th, 1877. He stated that, three days previously, his right eye had been wounded by a small piece of metal. I observed that the iris was attached to the lens at the outer part of the pupil by recent lymph, and that there was a small limited opacity of the lens. There was a small clear metallic body sticking at the margin of the adherent pupil. I made a small section of the cornea, more peripheral than the pupil, introduced a pair of iridectomy forceps, seized the body and a little piece of iris, but the body slipped from my grasp, and was sliding out of my reach. Fortunately, I had anticipated such an untoward event, and took care to have a pointed permanent magnet at hand. I introduced it into the wound. The metal was instantly attracted and extracted. The patient continued under my observation till February 16th. The opacity of the lens remained limited to the point wounded. I believe that the wound in the capsule was closed by lymph and healed. I have not seen or heard from the patient since.

CASE II.—Moses E., aged 32, millwright, consulted me at the Hospital on November 20th, 1877. He stated that, three-quarters of an hour before his visit, his right eye had been wounded by a chip of steel from a hammer. I observed a wound a little more than a line long in the ciliary region just at the corneo-sclerotic junction. One end of the wound penetrated the anterior chamber, as shown by the evacuation of the aqueous humour and a slight displacement of iris towards the wound. The wound was quite clean, and no foreign body was visible. The media was clear. The ophthalmoscope did not disclose the presence of any foreign body. I put the point of the magnet cautiously into the wound, and at once it proved the presence of metal within the sclerotic by the click and the attraction. By a little patient and careful use of the magnet, the metal was brought into the wound, and the end of it exposed so far as to enable me to grasp it with forceps. Having caught it, I easily extracted it. The fragment was a thin piece about one and a half lines long, one line in width at one end, and half a line at the other end. The patient recovered completely, and returned to work on December 10th following.

There can hardly be a doubt that the magnet saved the eye in both cases. In the first case, to have followed the sharp fragment with forceps would probably have inflicted irreparable damage, and indeed the body might have got out of the way altogether. In the second

case, the metal would but for the magnet probably have remained undetected, and have afterwards lighted up destructive inflammation. Even had it been detected, it would not have been possible, but for the magnet, to extract it without enlarging the wound, and that is not desirable in any part of the eye, much less in the ciliary region. By the magnet, the diagnosis was established, and the extraction was accomplished in the most delicate way.

## SELECTIONS FROM JOURNALS.

### THERAPEUTICS.

DIPHTHERIA AND LACTIC ACID SPRAY.—Dr. H. Beyer of Long Island City reports two cases of severe diphtheria successfully treated by the local application of dilute lactic acid in the form of a spray. He recommends the adoption of this remedy in all desperate cases of the disease.

DIET AND MEDICATION IN SACCHARINE DIABETES.—In the opinion of the medical officer of the Pennsylvania Hospital (as reported in the *Boston Medical and Surgical Journal* for March 21st), the best diet for a diabetic patient is: for breakfast, eggs, and any kind of meat or fish (except oysters), gluten bread, and tea or coffee with milk and without sugar; for dinner, tomatoes, lettuce, onions, spinach, string beans, meat, light sour wine, and lemons, or perhaps oranges, but none of the sweet fruits; for supper, about the same as for breakfast. None of the starchy foods, no alcohol, and no sugar, should be allowed. Among drugs, opium is the most valuable. Of this a large amount can be taken daily without producing any of the symptoms of poisoning. In one case, as many as seven grains were given *per diem*. This large amount of the drug had no deleterious effect further than the production of constipation. The opium directly, by diminishing all the secretions, or more probably by its action on the nerve centres, relieves the excessive thirst and voracious appetite, and diminishes the amount of urine and of sugar in the urine. In one case, the daily amount of urine was reduced from twenty-eight to eleven pints *per diem*. The total quantity of contained sugar was also reduced. Ergot, which acts in simple diuresis almost like a specific, may be used in saccharine diabetes with much profit in doses of one drachm of the fluid extract four times a day. Where the skin is rough and dry, jaborandi is of great value by reason of its diuretic powers. If jaborandi be used, the use of the opium and ergot must be stopped for the time being.

THE ALKALOIDS OF OPIUM.—The recognised opium-alkaloids are sixteen in number. The effect of each differs from the rest or from that of opium itself. Dr. Isaac Ott (*Journal of Nervous and Mental Diseases*, January 1878), reports a large number of experiments which, taken in conjunction with previous knowledge, lead him to conclusions summarised thus. 1. Cryptopia is narcotic; it excites and then depresses reflex action by an effect on the spinal cord, reduces the power of the motor nerves, abolishes sensation by an action on the spinal sensory ganglia, and lowers the heart-beat by an action on its muscular structure. 2. Thebaine is a spinal convulsant; it has no action on the motor or sensory nerves or on striated muscle. It reduces the heart-beat by an action on that organ, and increases blood-pressure by stimulating the cerebral vaso-motor centres. 3. Codeia is a narcotic and spinal convulsant; it produces a veratroid contraction of striated muscle, and depresses the heart-beat by an action on the cardiac muscle. 4. Chlorocodide is a tetanic agent. 5. Apocodide produces vomiting, coma, and death. 6. Narceine is soporific to cold-blooded animals, but not to man, and is a spinal convulsant. It does not destroy the motor nerves, as they act on thrusting a probe down the spine. It produces veratroid contraction of the muscle, and reduces the heart-beat by stimulation of the peripheral end of the pneumogastric. 7. Papaverine is narcotic and convulsant; the convulsions being partly spinal and partly peripheral, the latter, it is highly probable, from an action on the muscle. It diminishes the heart's contractions by peripheral action on the cardio-inhibitory apparatus. It also causes veratroid contraction of the muscle. 8. Narcotine is non-narcotic, and a spinal convulsant; it produces veratroid contraction of striated muscle, and is a very active agent to decrease the beats of the heart by an action on the cardiac muscle. 9. Cotamine is soporific, and paralyses, like curare, the motor nerves. 10. Hydrocotarnine is narcotic and convulsant. 11. Hydrochlorate of cotarnamic acid is a convulsant, and paralyses the pneumogastric. 12. Laudanosine and laudanine are tetanic agents. 13. Morphia is a

narcotic and spinal convulsivant. It produces veratroid contraction of muscle and reduces the heart-beat. 14. Oxymorpha has an action like morphia, only weaker. 15. Apomorpha is an emetic; it excites and reduces spinal reflex excitability, and diminishes the number of cardiac contractions. 16. Meconine is narcotic to cold-blooded animals, but not in doses of two grains by the stomach in man. It causes hyperæsthesia and paralysis of voluntary motion with general relaxation. It also produces a veratroid contraction. The opium-alkaloids all have a dominant action on the nervous system, causing first, increased exaggerated functions, and, if the dose be large enough, a paralysis of them. In the warm-blooded animals, this action is both on the spinal cord and on the cerebrum.

### MEDICINE.

**ABSCESS OF THE HEART.**—Abscess of the heart is not a very rare termination of myocarditis; and pyæmic abscess has been noted by Schroetter, Klob, Stanley, Latham, Bennett, etc. The following case, however, reported by Drs. Creveling and Button of Auburn (*New York Medical Record*, March 1878), is somewhat unique. Thomas Brennan, aged 63, entered the State Prison June 6th, 1877. On the 9th, 12th, 22nd, and 29th of the same month, he complained of cardiac pains, which were sometimes relieved by anodynes, and sometimes passed off without treatment. On July 15th, he was again attacked; the pains grew rapidly more severe, and did not leave him until his death (Nov. 30th). At the necropsy, the pericardium was found closely adherent over the entire surface of the heart; the endocardium was normal, showing no signs of inflammatory changes. A hard mass was discovered in the wall of the right ventricle, extending from about the middle of this cavity to near the top of the auricle, and encroaching somewhat upon both these cavities. On opening into the tumour, an ounce or more of laudable pus escaped, the greater portion of which lay opposite the upper half of the right ventricle. The abscess had not pointed, or given any other sign of spontaneous rupture. The external wall was about a quarter of an inch thick; the internal a trifle less. The whole amount of pus was situated in the muscular structure of the right side of the heart, which was still firm, giving no evidence of softening or degeneration; nor was there any indication of endocarditis or valvular disease.

**ALCOHOLIC AMAUROSIS.**—Dr. Arens (*Centralblatt für Heilkunde*) reports the case of a man, thirty years old, in other respects always healthy, who awoke one morning totally blind in both eyes. The patient himself regarded a three days' excessive indulgence in alcohol as its cause. The eyes were widely opened, fixed; the pupils were dilated and immovable; the ophthalmoscopic appearances were normal. The pulse was frequent, soft; the heart was normal. Sensibility and motility were intact in all the extremities. Large doses of Hunyadi János water, rest, diet, and cold water compresses on the head for four days, completely restored the vision.

**NOTES ON NERVE-DISEASE.**—In the *Centralblatt für die Medicin. Wissenschaften* is a summary of some interesting observations by Berger. The first relates to an early symptom of tabes dorsalis, which is described by Berger as consisting in the disturbance of the perception of pain of such a kind that stimuli of slight intensity, as well as tactile impressions of a slightly painful kind, such as needle-pricks, are perceived normally; but that more severe and often very strong stimuli produce no greater pain. This analgesia in respect to excessive stimuli may be present before other symptoms of tabes appear, and is of semeiotic importance. This peculiarity, as a common rule, is especially perceived in the skin of the lower extremities, and may finally be observed on the whole cutaneous surface and even on the mucous membranes. It appears to be a symptom depending on an initial lesion of the grey substance.—In a patient suffering from severe symptoms of vertigo, from which he was only free while lying on his back, no other symptom of brain-disease could be perceived, whilst other signs pointed to an intense gastro-duodenal catarrh. The treatment of the latter affection stopped the vertigo. A brother of the patient had already suffered for several years from the same complaint, which had become chronic.—Among the progressive and acute forms of bulbar paralysis, Berger distinguishes a form which appears among children from three to five years old—an apparently congenital disease of speech. The children speak very deficiently, as compared with their apparently normally developed intelligence and sound hearing. There is here an arrest of development of the bulbar centre of hearing, paresis of the bulbar nerves presiding over articulation and deglutition. There is often found, in these cases, paresis of one-half of the

body. In some cases, the individuals belonged to a family afflicted with neuropathic conditions; in another, there were found many congenital signs of degeneration (deficient phalanges, deficiency of the pectoral muscle of the right side, and webbed fingers). Continuous electric treatment has good influence. In the course of years, the condition is apt also to improve spontaneously.

### SURGERY.

**TRANSPLANTATION OF THE URETHRA TO THE PERINEUM.**—In the *Archiv für Heilkunde*, Heft vi, 1877, Dr. Wedemeyer reports a case of cancer of the penis, in which Professor Thiersch amputated that organ. After amputating at about the level of the pubic bone, and checking the hæmorrhage, a catheter was introduced into the urethra; an incision was then made along the raphe of the scrotum to the perineum, thus dividing the scrotum into two equal parts and exposing the urethra, the anterior termination of which was loosened from its attachment in the pubic arch for a distance of about four-fifths of an inch. A small incision was now made in the perineum between the posterior extremity of the scrotal wound and the anus, an inch and a half in front of the latter; the urethra was drawn through this opening, and its walls fastened in the borders of the wound. The operation was made under Lister's spray. Fourteen months after the operation, the patient reported himself as perfectly free from all inconveniences. He could project his urine forward at an angle of 45 deg. from the vertical line.

**TREATMENT OF ANEURISM OF THE AORTA BY ELECTRO-PUNCTURE.**—At the meeting of the Paris Société de Thérapeutique on March 13th, M. Dujardin-Beaumetz stated that this method of treatment was becoming general in France. Since last July, the operation has been performed three times; on two patients in M. Potain's wards, and on a patient of M. Ball's. A very marked improvement was obtained by this method in all the cases. The aneurisms were all of the thoracic aorta—two were seated at the origin of the aorta, and formed sacs occupying the left side of the thorax; a third was situated at the dorsal region, and originated in the descending portion of the arch of the aorta; in the latter case, the tumour was the cause of paraplegia. Five applications were made at intervals of three weeks, and produced a diminution in the paraplegia, and a great lessening of the pulsations. These aneurisms were not accompanied by any cardiac change. The method of operation was the same in all the cases; positive currents only were used on the needles inserted in the tumour, the negative pole being applied on the thigh. M. Dujardin-Beaumetz is inclined to believe that electricity acts here by setting up inflammation on the sac rather than by directly bringing on coagulation of the albumen and fibrin. He thus explains the tardy setting in of improvement, which only comes on from a week to a fortnight after the application of electricity. Summing up the facts known up to the present time, M. Dujardin-Beaumetz is of opinion that, taking the harmlessness of electro-puncture into consideration, this plan should take its place in ordinary therapeutics, and that it is the best of all treatments recommended up to the present time; he, however acknowledges that ice and iodide of potassium must first be tried. Ice applied externally also acts by setting up inflammation in the sac, and not by directly coagulating the blood; it has, in fact, been demonstrated that cold retards coagulation of the blood. Iodide of potassium administered internally is the only remedy which has afforded certain cures. At the same meeting, M. Paul stated that he had recently seen a case of aneurism of the brachio-cephalic artery in a syphilitic patient, which was cured by the use of iodide of potassium. M. Edouard Labbé also pointed out that M. Potain had observed an analogous case. M. Bucquoy also mentioned that he had seen two cases of very remarkable improvement in aneurism of the aorta, by the use of iodide of potassium and ice.

### OBSTETRICS.

**RETENTION OF THE PLACENTA.**—Dr. Hervieux, Physician to the Paris Maternity Hospital, reports a case of retention of the placenta in the uterus for twenty-one days after an abortion at the sixth month. The case reported (*Archives de Tocologie*, Dec. 1877) is one of great interest. It demonstrates that—1. The placenta may, after abortion or premature accouchement, remain for several weeks in the womb without undergoing change, and consequently without giving rise to any phenomena of putrid infection; 2. Expectant treatment may, in cases of prolonged retention of the placenta, be followed by an excellent final result, and in some cases have advantages over forced delivery.

## BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 4TH, 1878.

### CONFERENCE OF HOSPITAL MANAGERS.

THE proposition to hold a Conference of Hospital Managers, made in these columns recently by Mr. Henry C. Burdett, and warmly recommended by Mr. Custance, the Secretary of the Metropolitan Hospital Sunday Fund, and Mr. T. Holmes, Chairman of the Out-patient Reform Committee of the British Medical Association, has, after these professional endorsements, been submitted to public discussion, and has been received with great favour, as having obviously great economical advantages, and being likely to prove extremely useful and attractive to the charitable public, and probably beneficial in the end to all the institutions concerned.

It is, however, to be feared, if all that we hear be true, that many of the hospitals will oppose any such scheme, and for mixed reasons. The majority of the managers, we are informed, object to publicity; and, should a formal proposal be made to some of the metropolitan charities, unless the views of these gentlemen be modified, they will refuse to take part in any Conference if reporters are allowed to be present. Others, again, object to move in the matter on the ground that they have perfected their system of management, and that such a Conference can do them no good, as they have little or nothing to learn from their neighbours. Others, again, object altogether to any such movement; because they regard all outside interference, no matter how modified a form it may assume, as utterly foreign to the welfare of these charitable institutions. These, and several other minor arguments, will have to be got rid of before anything like a real Hospital Conference can be held. For our part, we are fully convinced that these objections, which, for obvious reasons, will probably never be seriously and publicly put forward by the authorities of any charity as a ground for refusing to attend the Hospital Conference, constitute strong arguments in favour, not only of such a movement as is now proposed, but of a Royal Commission of Inquiry. Those who object to publicity must have some strong reason for wishing to avoid it; and the animus which all attempts at reform excite in the minds of some influential supporters of our public charities would be ridiculous if it were not a serious, and, we fear, a growing evil, leading to great abuses. Be this as it may, however, we counsel whoever may be induced to attempt to organise the first Hospital Conference to insist upon it being, in every sense of the word, a public one, based upon the broadest and widest principles, and including, as far as possible, not one group or a series of groups, but all the hospitals: endowed or unendowed; with and without medical schools; metropolitan and provincial. Each institution, with one hundred beds and upwards, desiring to be represented at the Conference, might fairly be invited to send the chairman of the committee of management, a representative of the honorary medical staff selected by his colleagues, and its principal paid official. Institutions with less than one hundred beds might reasonably be content to be represented by the chairman of their managing committee. In this way, a Conference could be called which would embody representatives of all the views, the experience, and, we may add the blemishes, of our present hospital system. Such a Hospital Conference, so constituted, commanding as it would do the confidence of the public, and insuring a fair and full discussion for every point of practical importance connected

with the management and conduct of the hospitals of this country, must result in great benefit to the vast interests at stake. We, therefore, hope, in spite of the preliminary difficulties which will have to be overcome, that some practical steps will at once be taken in the matter. Why should not the treasurer of one of the endowed hospitals, in conjunction with the chairman of one of the voluntary charities, summon a preliminary meeting of the representatives of all the metropolitan hospitals having medical schools? In this way, the views of the more influential and representative of the hospital managers might be ascertained, and the subject could then be fairly discussed on its merits. We shall hope to hear that one of the treasurers in question has consented to allow some such preliminary gathering to assemble in the board-room of one of the Royal Charities.

Turning, now, to the subjects which such a Conference might fairly be asked to consider and discuss, one is embarrassed at once by their number and importance. Hospital finance and hospital accounts would, of course, form one of the most interesting sections. In the former, it might be shown, to many a metropolitan hospital manager, how the county infirmary manages, without large invested funds, to keep out of debt. Glasgow, for example, might teach the London Hospital a lesson of thrift, which the latter institution could profitably study. The working population of the port of Glasgow subscribe £6,000 a year to the Infirmary there; whereas the same class of the population, which in London supplies nearly all the accident cases, subscribes practically *nil*. Here is surely one striking example of the profit to be derived from a knowledge of how our neighbours minister to their own necessities. The thrift of Glasgow might well be imported to the East of London. Doubtless a distinct organisation, on the Glasgow model, if fairly and patiently nurtured, would give the London Hospital, in ten years, an income from the port of London not far short of £10,000 *per annum*.

Take, again, the matter of hospital accounts. It recently happened that the editor of one of the Charity-guides hit upon the expedient of publishing an alphabetical and comparative table, showing the relative income and expenditure of all the London hospitals. What was the result? A careful examination of the published statements of accounts, issued by these institutions—no two of which were based upon the same principles—convinced him of the hopeless nature of the task he was attempting; because no tables that he could thus prepare would constitute a reliable basis of comparison. In this matter, the Council of the Hospital Sunday Fund have done much good; but the value of their work is neutralised by the fact that they have not the courage to publish the returns made to them by the metropolitan hospitals. We hope, however, that this year wiser and more liberal views will prevail with the Hospital Sunday Fund authorities; and that they will give to the world the results of much labour, which, under existing circumstances, is comparatively useless.

Take, again, the question of supply. We do not say it will ever be possible to carry out any such scheme; but it would, at any rate, be interesting to hear the views of hospital managers generally upon the question of raising the voluntary income of all the metropolitan hospitals, for instance, by one common agency. For our own part, we believe a vast saving in expenditure might be secured by the establishment of a central office for all the London hospitals, from which the voluntary income might be collected; and in this way duplicate and multiple appeals might be abolished. In the same way, following the example set in Paris by the Sisters of Mercy, a central store might be established in London, at which all the hospitals might purchase, at a little over cost price, every article of consumption from an egg to a wooden leg. An arrangement of this kind would tend to reduce the large discrepancies as to relative cost of patients which at present exist between one hospital and another. Any one purchasing at the store would have a guarantee that the article supplied was not only of moderate price, but the best and most suitable of its kind. Under existing circumstances, we have found one hospital giving a hundred per cent. more than another for the same necessities in daily use. It was

only a fortnight ago that our attention was called to the fact that, whereas the cost per week of each in-patient at one of the metropolitan hospitals was but 19s. 7d., at another it amounted to £3 19s. 5d. The discrepancy of these sums surely suggests food for reflection. Mr. Timothy Holmes has well pointed out that a Hospital Conference would create more enlightened views on subjects of hospital management, as well as on that of hospital finance. There are questions, such as that of medical teaching, which, though of the greatest public importance, are relegated entirely to medical men; while the general administration of the hospitals, though of the greatest medical importance, is regarded as the exclusive province of laymen.

Again, the general question of the uses and abuses of hospitals, and especially of the out-patient departments, would form an interesting subject for discussion. By means of a Conference, it might be possible to arrive at some practical solution of this question, and to secure a general trial of the new system. At the present time, reforms of this character are usually left to outside bodies, who, having no control over the hospitals or influence with the managers, find it impossible to carry through any scheme, however excellent, or to secure the adoption of any reform, however urgent.

If a Conference were held, the reproduction of exploded abuses would soon cease. At the present time, much money is annually wasted upon plans which, were the practical experience of all the hospitals available, would soon be saved for better purposes. Take Parian cement as an instance. It has been proved over and over again to be most porous, absorbent, and expensive; yet it would not be difficult to find that large sums have been expended to procure it for some recently built hospital, because the managers believe it to possess exactly the opposite qualities. They manage these things better in America. When the plans of Dr. Billings were accepted for the Johns Hopkins Hospital at Baltimore, he was sent to Europe by the trustees to ascertain if any, and if so what, portions of his plans had been tried at the various hospitals, and with what results. In this way, he was enabled to modify and improve his designs, and, without great expense, to put many of his schemes to the test of practical experience.

But why multiply examples? In all respects, a Hospital Conference would prove most interesting, instructive, and beneficial. Many theories would be exploded; many reforms would be made popular; and much needless extravagance and waste of public money would be prevented. If we are to have a parliamentary inquiry into the management of our hospitals, nothing could better conduce to a clear understanding of the subject, could better pave the way for a public inquiry, or even possibly render such an inquiry unnecessary, than a Hospital Conference. Under all the circumstances of the case, we hope Mr. Burdett's proposal will secure the public and professional attention and support it justly merits.

#### CONSULTANTS' ETIQUETTE.

Is there in London, or in Great Britain, any "pure" consulting physician or consulting surgeon? By which we mean any physician or surgeon whose professional occupation it is to receive patients only in consultation with another practitioner, as a barrister receives, advises, and acts for clients only in consultation with a solicitor or a junior at the bar. This question, which we have mooted before in these columns, is again suggested by a letter from a graduate of the London University in general practice, on "Consultants' Professional Etiquette". He complains that, in two cases, patients at the time under his treatment were prescribed for by "consultants", who were aware that these patients were under his care at the time, without any communication being made to him. Our correspondent complains of this as being unfair to him and to his patients, and describes it as a breach of "consultants' professional etiquette". In our opinion, he is correct in describing the course of which he complains as a breach of etiquette. It is, however, one which is, we believe, not uncommon, and which arises out of the

practice which widely, if not universally, prevails of combining the functions of consultation practice with those of ordinary family and general practice. If a patient call upon a general practitioner of the class ordinarily so described, and at the same time inform him that he is under the treatment of a neighbouring practitioner, it is well understood that it is his duty either to propose a consultation with that practitioner, or, if any valid obstacle to such consultation exist, to communicate any opinion which he forms, or any medical treatment which he advises, by letter to that practitioner. On the other hand, the waiting-rooms of a London hospital physician or surgeon in good practice are filled with patients, some of whom come to him as their sole medical attendant, some are receiving fitful and occasional attendance from a family medical adviser, and some are actually under the treatment of the latter. Now, there seems little doubt that the obligations of the hospital physician to communicate with the family practitioner in attendance are the same as those of the neighbouring practitioner consulted under similar circumstances would be; but there is, as our correspondent's letter illustrates, reason to believe that that obligation is often very imperfectly fulfilled. This does not certainly arise from any general unwillingness to conform to a high standard of ethical propriety, but from the indefinite character of the professional relation of the consulting physician to the patients who call upon him. Hybrid relationships breed mongrel results. Between the patient who calls and frankly adopts the "consultant" as his sole personal adviser for the occasion; the patient who calls with "his medical man"; the patient who calls with a letter from "his medical man"; the patient who calls at the request of his medical man, or with his consent, and with the expectation of the latter to see his patient at once again with a letter expressing the consultants' opinion; and the patient who, being dissatisfied with the results of his former personal attendant in a particular instance, desires to change his adviser and take "higher advice"—there are many shades of difference; and, in the course of an active morning's work, consultants are sometimes apt to disregard the finer *nuances*, and with results such as our correspondent describes. A guinea fee will not remunerate a busy physician for diagnosis, prescription, and a descriptive letter to a practitioner, which, under such circumstances, may involve further correspondence. But a patient who calls under the circumstances described by "M.B." is very apt to consider that as the proper *honorarium*. By treating a patient who calls alone and without a letter from his doctor as his own, the consultant is probably for the moment more likely to consult his own pecuniary interests; and, although very few London hospital physicians or surgeons are not willing to place conformity to established professional customs above pecuniary considerations, still the unconscious bias of other palpable considerations is evidently to obliterate the faintly seen lines of a course which, by stripping the case of all superficial details, become more distinct. We believe that these misunderstandings of which our correspondent speaks arise very commonly from the hybrid position of consultants, who are, as a general rule, almost as much general and family practitioners as consultants, with the distinction that the larger number of patients call at their houses and pay an uniform guinea fee.

Whether it might be feasible, or whether, if feasible, it might be desirable, to establish a class of "pure consultants" in the medical profession, is a question which is, we think, ripe for discussion. Such men would, on application to their Colleges, receive recognition as "consulting physicians" or "consulting surgeons", as barristers of more than ten years' standing and recognised position may, upon application to and with the approval of the Lord Chancellor, be "called within the bar", or "take silk", as it is called. They can then only "lead". They have precedence and seniority; they receive higher fees; but they must always have associated with them in every case a junior. The opinion of a consultant of this recognised position would be dignified and well marked. His consulting fees would be larger;

his time would not be taken up with trivial cases. He would receive full particulars and prepared details of the case for consultation, and would give a written opinion in all necessary detail, as counsel do. His fees would be marked on his medical report from a higher standpoint and over a larger range. He would not be fagged to death with trivial cases; he would not be forced to retire from hospital work and clinical teaching just at the time that his abilities and experience had ripened to their highest maturity. He would have time to continue scientific and literary labours; and the most eminent practitioners would be less overwhelmed with an exhausting mass of ordinary cases; they would have more time for other than routine work, and would be more truly leaders. Their incomes would not be less; their lives would be longer; their work of the highest and most noble kind; and their sphere of action would be defined in a most satisfactory sense.

#### UNQUALIFIED ASSISTANTS.

THE Lord Mayor of Dublin has been moved to some indignant observations, by discovering incidentally that a practitioner in that city employed an unqualified assistant. He is reported to have said, among other things, that he should like to know the mode in which those compounding departments of the profession were carried out; whether those young gentlemen had passed qualifying examinations, and whether they had received a diploma. He always understood that young gentlemen engaged in mixing medicines should pass through an examination, and get a certificate from the proper authorities. As a public servant, he should like to know whether the prescriptions sent into medical establishments were compounded by gentlemen who had obtained a proper certificate or authority, and whether there was any check on those young gentlemen. He was surprised that no means had been adopted to protect the public from having their medicines improperly compounded; and, as far as he was personally concerned, such a state of things would put him on his guard in future.

There is here a certain mixture of questions as to the employment of unqualified assistants by medical men and by chemists and druggists—customs both of which largely prevail in England, but of which the first at least is very rare in Ireland. The *Medical Press*, commenting upon the Lord Mayor's observations, says:

"It will hardly soothe the indignation or allay the surprise of the Lord Mayor and the Dublin public, to learn from us that the employment of young men to whom the practice of medicine is a dim vision is one of the commonest of occurrences; that in England a considerable proportion of the doctoring amongst the working classes is done by assistants who are employed *because* they have had no regular education and possess no qualification, and therefore cannot enter into rivalry with their masters; that there is nothing unusual in the doctoring of large and populous districts in the manufacturing counties by three or four such unlicensed assistants, who are in charge of separate establishments, and supposed to be under the ownership of one general practitioner; that it is a practice for some general practitioners who work in this line to sign certificates respecting the causes of death of persons whom they have never seen alive; and that, in fact, law and custom allow the life and death of thousands of persons to be entrusted to unqualified assistants who have learned most of what they know upon the vile bodies of their masters' clients, and who pursue their experiments upon such bodies under the cloak of their masters' qualification. The chief magistrate of Dublin is horrified at the notion of death-doses being dispensed to his fellow-citizens by ignorant and careless boys. What would he say if he realised the vision of such young gentlemen not only making up the medicine, but prescribing it themselves?"

This is a very unqualified and overdrawn statement; but it puts forward, in words which we should be glad to see contradicted, some of the most obvious objections to the employment of unqualified assistants; and side by side with these observations of the Dublin writer upon the utterances of the chief magistrate of that city we may put the following remarks of Mr. Bushby, one of the most experienced of our metropolitan magistrates, at the close of a baby-farming case where there were suspicions of systematic foul play.

"He felt it necessary to make some remarks upon the certificates of death which had been produced before him. Although the certificates were intended for the Registrar-General only, it was much to be regretted that, the medical gentleman called in to attend the child Dugoy being merely an assistant, Dr. Flack should think his account of the cause of death sufficient warranty for the issue of a certificate of death wherein Dr. Flack certified, 'I attended'. Mr. Bushby believed, of course, that it was done without any evil intention; but thought it was a matter for very great regret that, although the certificates were intended only for the Registrar-General, a medical gentleman of position should certify what was not strictly true."

The medical profession is asking now for an amendment of the Medical Act which shall give more effectual protection to the public and profession against the dangers of medical practice by unqualified persons. How can this be fairly done if such evidences exist of the encouragement of unqualified practice by members of our own body? We are claiming that unqualified persons shall not wear borrowed plumes of apparent qualification, and this for our protection and that of the public; but what is this except another phase of the practice against which we are seeking legislation?

#### ANTI-VACCINATION STATISTICS.

WE have thought it of some importance to examine the recent statements made by Mr. Hume-Rothery, who styles himself President of the National Anti-Compulsory Vaccination League, in which he puts forth startling figures regarding the prevalence of small-pox in the French and German armies during the war of 1870-71. These figures, he observes, ought to induce every one "to promote a measure for the speedy and entire repeal of the unjust and cruel Vaccination Acts". As in many other instances, where figures are used, not for arriving at a just conclusion, but for promoting a particular object, the numbers quoted are so partially given, and in such an indistinct manner, while much that would explain them is kept back, that they are made to propagate error among those who have not the opportunity or do not care to take the trouble of analysing them. Instead of enlightening, they serve the unworthy purpose of deceiving the unwary reader. Mr. Hume-Rothery, in writing of the small-pox which prevailed at the time of the Franco-German war, mixes up the statistics of the deaths from this disease in the respective armies with those which occurred among the civil population in Prussia, and among French prisoners in the country, in such a way that it is difficult to separate them without special care; and he quotes the general order in the French army, which requires every French soldier on entering a regiment to be revaccinated, as a proof that the 24,000 deaths, which have been recorded as having resulted from small-pox in the French armies during the war of 1870-71, all occurred among revaccinated persons at that particular period.

Now, what are the facts regarding the war of 1870-71 in this regard, and what is the evidence as to the protection afforded against small-pox by vaccination in the German army? We can gather some valuable information on the latter point from the statistics, carefully collected from official records, by General-Arzt Dr. Roth and Ober-Stabsarzt Dr. Lex, in their *Handbuch der Militär-Gesundheitspflege* (vol. iii, Berlin, 1877, page 360, etc.)

As to the French army, it is undoubtedly true that the rule is for every French soldier, without exception, to be revaccinated on joining his regiment. This regulation was enforced in the Imperial army up to the outbreak of the war; but afterwards, when large levies were hastily collected, and especially among those which were raised after the collapse at Sedan, but little attention was paid to it, and it may be said for the time to have fallen practically into abeyance. It is well known how largely the civil element entered into the composition of the so-called "Army of Defence" of Paris during the siege; and how impossible it was at the time to carry out military regulations, with even an approach to strictness, in a great part of it. In this army, the mortality from small-pox, during the first siege, amounted to 67.6 per thousand; while in the generally well protected German army, surrounding the city, the mortality from it was almost *nil*. During the

whole war, the mortality in the German army, though brought into close contact as the troops were on all sides with the disease, amounted only to 0.3 per thousand. The fact was, that small-pox was prevalent in the civil population of several departments of France in 1870; and, among these subjects of the disease, it was notorious that vaccination had been very imperfectly attended to, partly from heedlessness, and not a little from opposition on the part of some of the more ignorant priests to the practice. Under the trying circumstances of the war, the measures which would have been taken in more quiet times to prevent the spread of the disease were neglected; it was widely disseminated by recruits among the armies of France; and, when large bodies of French prisoners were carried into Germany, it became epidemic there also, and gave rise to a considerable mortality among the people in that country. But, in the German army, the mortality from small-pox always remained relatively small; the aggregate presenting, as before mentioned, a ratio of 0.3 per thousand of troops.

The history of vaccination in the Prussian army offers remarkable evidence of its prophylactic power against the disease of small-pox, and affords a strong protest against the statements advanced by members of the society over which Mr. Hume-Rothery presides. Vaccination, or revaccination in case of the previous performance of vaccination, was first ordered to be adopted as a regulation in the Prussian army of 1831, but difficulties were met with from several directions in carrying out the order, and it was not until 1835 that it was systematically executed. When once the due performance of the measure was secured, its beneficial results were made manifest beyond all reach of cavil; whereas, in the ten years 1825 to 1834, the number of Prussian soldiers who had died from small-pox was 496, the number in the following ten years, from 1835 to 1844, was only 39. In the next ten years, 1845 to 1854, the number was still further reduced to 13; and from 1855 to 1864, only 12 deaths from small-pox occurred in the Prussian army. The next decade was interrupted by the great, though comparatively short war of 1866, between Prussia and Austria, and, in this year, there were 8 deaths among soldiers from small-pox; but, as shown by the sanitary statistics emanating from the Prussian War Office, all these eight fatal cases occurred in soldiers who from the circumstances of the time had not been revaccinated. In the following year (1867) only two deaths occurred in the Prussian army from small-pox, and during the years 1868 and 1869 only one in each year. Surely, when the liabilities to occasional errors in the operation of vaccination from some imperfection in its performance, or from defect in the quality of the vaccine lymph, is taken into account, no stronger evidence could be adduced to show the efficacy of vaccination in warding off the disease of small-pox and modifying its severity in case of its occurrence, than that which is brought to light by the foregoing statistics. The war of 1870-71 was exceptional in respect to the vast numbers of the troops, and especially of what may be strictly regarded as the civil population temporarily employed as soldiers, that were brought into the field, the vast area over which the military operations extended, the length of time during which they were carried on, and the fact of their being actively pursued throughout the winter; so that the presence of a large proportion of men who had not been revaccinated on joining the German armies, not to mention the neglect of other precautions, can be no matter of surprise. Yet, even under these circumstances, notwithstanding the exposure to a wide-spread epidemic of small-pox in France and among the French prisoners carried into Germany, the mortality from this disease among the men in the German army only amounted, as already shown, to 0.3 per 1,000. Among the general population of the country, the proportion of deaths after the epidemic had been introduced from France, was considerably greater, viz., 2.4 per 1,000. The difference between the proportion of deaths in the civil population of Prussia from small-pox, and the relatively small ratio in the army, year by year, after the practice of revaccination was introduced into it, is one of the most striking facts in the history of vaccination in that country. In one year, in 1848, when there were as many as 4,691 deaths from small-

pox in the civil population of the country, there was not a single death from the disease in the whole Prussian army.

Mr. Hume-Rothery has thought fit to place at the head of the letter which has given rise to these remarks, the title of the "Vaccination Craze"; but what condition of craze can be assigned to that person who, with all the proofs before him of the protection against a most contagious and loathsome disease that the wonderful discovery of Jenner has offered to mankind, still persists in doing all in his power to deprive the world of its benefits? As the late Dr. Parkes has well observed: "He who impedes vaccination is committing an unjustifiable offence against the community in which he lives, and if that community realised all the facts of the case, it would not tolerate his conduct for a day".

#### OUT-PATIENT HOSPITAL DEPARTMENTS.

SIR WILLIAM GULL's motion, at the recent meeting of the Charity Organisation Society, in favour of the establishment and extension of Provident Dispensaries, together with the lucid and convincing arguments he advanced in support of his proposition, once more draws attention to the urgent necessity of hospital reform.

The experience of thirty years' close attention to the diseases of the poorer classes, fifteen of which were passed at Guy's Hospital, has taught Sir William Gull that the present system of out-patient relief pursued at the hospitals is highly unsatisfactory, or, as he himself expressed it, "a disgrace to any civilised community". This is strong language; yet the speaker is no sciolist.

It is a notorious fact that a fractional part only of the out-patients who crowd the London hospital doors can obtain more than a few hurried words of advice from the medical staff, let alone careful diagnosis or treatment; yet so rooted is the conviction among the poorer and uneducated classes that skilled medical treatment is to be found at the hospitals only, that thither they flock, often after a weary and painful journey, necessitating the loss of a day's work or the neglect of household duties, only to receive instructions to return for treatment some other day. To make matters worse, the greater part of those presenting themselves for gratuitous medical relief stand far more in need of the friendly services of the butcher and baker than of the physician or surgeon; many others are not in such straitened circumstances as to warrant their application for either gratuitous advice or treatment, and the scant time at the disposal of the medical staff is sorely wasted and trespassed upon, at the expense of *bona fide* and more serious cases requiring immediate and close attention. To obviate, then, these abuses—the necessity of the painful tramp to the hospital, the weary and anxious time wasted in the densely packed waiting-rooms (undoubtedly tending to aggravate the patients' disorders)—no less than to afford some relief to the overtaxed and totally inadequate medical staff, Sir William Gull once more urges the immediate establishment and extension of Provident Dispensaries throughout the metropolis. With this aid, in place of the present loose and slipshod method, or rather want of method, in administering out-patient relief, a proper and carefully organised system might be at hand to meet the exigencies of every case, the more grave of which could be treated clinically at home. The same tale has been told over and over again by the late Sir William Fergusson, by Dr. A. P. Stewart, by Mr. Timothy Holmes, and by other leading members of the consulting branch of the profession, as well as by Dr. Joseph Rogers, Mr. Nelson Hardy, Mr. Stephen Alford, and other representatives of the class of general practitioners in the metropolis, not to speak of their provincial *confrères*. In an interesting and extremely able paper read before the Metropolitan Counties Branch of the British Medical Association (see BRITISH MEDICAL JOURNAL, March 16th, 1878), Mr. Timothy Holmes pointed out that at the hospitals admission is too indiscriminate, so that a number of persons are admitted beyond the powers of the institutions properly to deal with; and that it is impossible, in those hospitals attached to medical schools, to give that instruction which

the students ought to derive from the out-patient practice. As a consequence of this excess of numbers, the poor are made to wait an inordinate time for the advice given; and such advice, when obtained, is often hurried and worthless. Mr. Holmes also shares the general views of the profession when he states that indiscriminate out-patient relief pauperises, and thus tends to demoralise, the persons to whom it is administered, and deprives medical men of a substantial part of the fund from which they draw their subsistence: an injustice and an injury both to the givers and to the receivers.

Sir Charles Trevelyan, by his warm advocacy of the extension and establishment of Provident Dispensaries, and by his carefully prepared arguments and statistics, all bearing in favour of the scheme in project, is the mouthpiece of a vast portion of the lay community. Having the amelioration of the working classes at heart, they are strongly in favour of the abolition of gratuitous medical relief, and of the adoption of provident institutions, as being eminently calculated to bring about a healthy independence and a stricter observance of hygienic laws, the simplest of which, under the present state of affairs, are woefully neglected.

It may be fairly assumed that Provident Dispensaries will turn out to be of substantial advantage to the profession at large; and it is beyond doubt that their extension will deal a staggering blow to the pernicious custom of chemists and other unqualified persons of prescribing for the poor and working classes, and thus damaging and encroaching illegally upon the legitimate rights of the qualified practitioner.

#### THE ARMY AND NAVY MEDICAL SERVICES.

WE have authority to state that the naval medical service is in urgent need of medical officers, and advertisements have been issued inviting candidates to offer themselves for examination. It is understood that such candidates as come forward and can pass the examination will not go to Netley for the usual training, but will at once be appointed to duty in ships about to be commissioned. We are unwilling to take any advantage of the necessities of the public service, nor would we say anything which would prevent men from coming forward to fulfil its requirements at a period which may possibly prove to be one of national emergency. We feel no doubt, indeed, that if any real necessity arises, young medical men will prove not less patriotic now than before, and, overlooking shortcomings, respond to the call. We cannot help observing, as this is, indeed, the proper time to observe, that the Lords of the Admiralty, like the Secretary of State for War, have incurred a very serious responsibility in failing to keep that service in so efficient a condition as to be able to command the requisite number of officers for the requirements of the service without, on the first occasion of emergency, having recourse to special and urgent appeals. It has long been notable that the claims of the medical officers of both services have been too often treated with a certain superciliousness and neglect; that, when the necessity for some improvement of the terms of service has been forced upon the authorities, it has been yielded with a niggardly and grudging hand, and that such reserves and deficiencies have prevented it from being accepted as a settlement of the question at issue. It is to the neglect and ill-treatment of this service, and to this alone, that their present unpopularity with the medical profession must be ascribed; and to this cause it is due that we now find both services inefficiently manned, and that the heads of both departments are unable to command a sufficient staff for the purposes of the army or of the navy. No doubt, the medical profession will, on this as on previous occasions, distinguish itself by a generous patriotism; but if it omit to insist, as a preliminary, upon the improvement of the conditions of service in such a manner as might prove embarrassing to the public service, it will at least have established a claim to a prompt and generous consideration of those causes of dissatisfaction which have led to the present depletion of the ranks of the services.

#### THE ARMY MEDICAL DEPARTMENT.

WE publish in another column a letter addressed to the Chairman of the Parliamentary Bills Committee from the War Office, inquiring as to the average earnings of young men entering the medical profession, with a view, probably, to establish a standard which shall regulate the War Office in determining the financial conditions required to make the Army Medical Department attractive. Probably, some of our readers will assist by suggesting data for furnishing the answer. It is, however, tolerably clear that it must be very difficult to establish any average, and that widely different estimates are likely to be formed, according to the different experiences which suggest them. We shall, however, of course, be very happy to give the assistance asked in the form laid down; though we doubt whether more than merely accessory information can be gathered in this way towards the satisfactory re-establishment of the conditions of service in the Army Medical Department.

A MORTUARY properly fitted and furnished has just been erected in the grounds of Mile End Workhouse, in the place of the small shed which has for a long time been used for the purpose.

THE *conversazione* of the Pharmaceutical Society of Great Britain will take place on Wednesday evening, May 15th, at 8 o'clock, at the South Kensington Museum.

THE President and Council of the Medical Society of London have issued invitations for a *conversazione* to be held in the Society's rooms, 11, Chandos Street, Cavendish Square, on Monday evening next. Previously to the *conversazione*, at 8.30, Dr. Alfred Carpenter will deliver the annual oration; the subject being, "Alcoholic Drinks, as Diet, as Medicine, and as Poisons".

MR. ROBERT CHARLES MOON, surgeon, and Mr. Charles Darnley, chemist, have been committed for trial, after magisterial inquiry, on the charge of administering drugs with the felonious intention of procuring abortion. In the case of Moon, the result having been fatal, the charge assumes a very serious aspect indeed.

MR. SAMUEL WOOD, who has been for a long series of years surgeon to the Salop Infirmary, has lately resigned, and has been appointed honorary surgeon to the Infirmary; and Mr. W. Eddowes has been appointed to succeed him in active duties. A warm vote of thanks was passed to Mr. Wood for his long and valuable services to the institution.

DR. DYKE, Medical Officer of Health for Merthyr Tydfil, in reporting on a recent outbreak of typhus in Dowlais and Merthyr, ascribes its extension to the uncleanness and want of ventilation of the houses, and recommends the inspection of every house in the parish, and the institution of the necessary measures to compel the owners to provide the means of sufficient ventilation.

DR. CHARLES BEAUME, a French physician settled in Crete, has retired with the insurgents into the mountains, and is doing his best to help the wounded with skilful medical assistance. The difficulties of his task appear to be great, and the hospital appliances at hand are few; but the brave Frenchman is described as being nothing discouraged, but toiling on with lighthearted energy in his kindly professional work.

AN excellent suggestion made by Dr. J. Lawrence Hamilton in the *Times* of April 29th, that the Directors of the South Kensington Museum should set aside space in the Building Materials Department—for the exhibition of suitable specimens and models showing faulty materials, slovenly careless workmanship or scamping, and the various causes of deterioration in building materials on land and in the construction and fitting of ships—has, we are informed, been adopted.

DR. E. SYMES THOMPSON commences, on Tuesday, May 7th, a series of Gresham lectures on Hæmaturia.

DR. COLAN, the senior medical officer under Sir George Nares in the late Arctic Expedition, and who upon his return was promoted to the rank of Deputy-Inspector General of Hospitals, was recently sent on duty to the hospital at Jamaica. His friends will regret to learn that he has suffered from an attack of yellow fever, contracted in his unremitting attention to a fatal case which was treated in the hospital. He is now happily convalescent.

ON Tuesday last, April 30th, Dr. Benjamin Howard made a series of demonstrations at the College of Surgeons of England, before several members of the Board of Examiners in Anatomy and Physiology, showing the effects of change of position on the relations of the upper air-passages. Dr. Howard explained, by means of anatomical preparations, a simple method of securing complete elevation of the epiglottis, independent of forcible traction of the tongue, which he considers needless for the restoration of asphyxiated persons, and based on false theories. He also showed how a free air-way may be maintained from the posterior nares to the glottis quite independently of any position of the tongue. These principles will shortly be made public. The demonstrations were attended to with great interest, Mr. Wood and several other of the examiners entering into a lively discussion on several of the points brought forward by Dr. Howard.

#### WESTMINSTER HOSPITAL.

DR. ALLCHIN, F.R.S.E., who had previously held the Lectureship on Practical Physiology and Histology with much distinction, has been elected to the chair of Physiology, on the resignation of Dr. MacLure. Mr. Murrell has been appointed Lecturer on Histology and Practical Physiology. The lectures—eighty in all—on this subject, we are glad to see, have been divided into a summer and a winter course. The division of this course is an excellent innovation, as it enables students to take a course in the summer, and so relieve their overcrowded winter curriculum. The lectures on *Materia Medica* and Therapeutics are to be included in the second summer course. This is a step towards the reform we have long advocated in these columns; and we congratulate the School upon its courage in introducing this modicum of reform. Dr. Allchin has been elected Dean, in the place of Mr. Cowell, resigned.

#### READING THE BAROMETER.

THE excessively large amount of rain which fell on the 10th and 11th of April was remarkable, not only for the amount, but also for the short time in which it fell, as about two and a half inches fell between 9 P.M. on the 10th and 9 A.M. on the 11th. The total fall recorded at several stations on the north-west of London was nearly three and a quarter inches: about two and a half inches at Tottenham, Stoke Newington, and Hackney, less at Croydon, and two and three-quarter inches at Greenwich. The barometer-readings were unusually high for such a heavy rain, and the fall in the barometer was very small at the time, only about one-tenth of an inch, which took place before midday on the 10th, so that few persons expected rain. The readings from before midday on the 8th to about the same time on the 10th were the same, viz., 29.9 inches; but a rather quick fall had occurred on the 7th and early part of the 8th. The wind was easterly, which accounts for the high barometer, and consequently misled those who look to the barometer as almost necessarily indicating dry or rainy weather, accordingly as it is high or low. The barometer merely indicates the varying weight of the column of air at the locality where it is placed, and is far more closely associated with the direction of the wind than with rainfall, as it is usually high with northerly, north-easterly, and easterly winds, and low with southerly, south-westerly, and westerly winds. As south-westerly winds reach us from the sea, the air is more highly charged with moisture than when easterly winds blow, which come to us from the land. A fall in the barometer, with easterly and north-

easterly winds, is an indication of approaching change of wind or of heavy rain, especially if the rain do not occur soon after the fall. To make a reasonably accurate forecast of the weather, we must, therefore, take into consideration the curve described by the barometer-readings for some days before (this is now published in most daily newspapers), and the direction of the wind, and, if convenient, the variation in the temperature; and not merely look at the barometer, and say to ourselves it stands at "fair" or "fine", and it will, therefore, be fine weather. In this case, the wind being easterly from the Saturday to the Friday following, the fall in the barometer on the Sunday was significant of change, and possibly of rain. In all cases, the opinion has to be framed rather on the rise and fall of the barometer than on its height at a given time. We hope this will be satisfactory to those who have written to us on the subject.

#### HYDROPHOBIA FROM THE BITE OF A CAT.

ON Saturday last, an inquest was held by the Manchester city coroner on the body of Eliza Jane Holloway, aged 26, who died two days previously in the Manchester Royal Infirmary, and a verdict of "Death from hydrophobia from the bite of a cat" was returned.

#### THE HISTORY OF THYMOL.

DR. LEWIN, assistant at the Pharmacological Institute in Berlin, writes to us from Berlin in respect to a remark in a recent number of the JOURNAL relating to the first researches on thymol. He gives us the following historical details. Thymol was, he says, first found and described not by Lallemand, but by Kaspar Neumann, in the year 1719. In respect to its uses in medical practice, Paquet (*Bulletin Général de Thérapeutique*, 1868) first mentions that he had used it in a few cases as an antiseptic, on the recommendation of the pharmacist Bouillon (*Ibid.*, page 508). It is stated in Paquet's communication that he experimented with a "syrupy preparation", therefore with that which was certainly not pure thymol, which has a beautiful crystalline form. The first investigation of this material was conducted by Dr. Lewin, on the recommendation of Professor Liebreich, in the Pharmacological Institute of the University of Berlin, and is reported in the *Centralblatt für die Medicinischen Wissenschaften*, May 1875, as well as later in Virchow's *Archiv*, Band 65, 1875. From this research there arose at once the modern extended practical application of thymol, as Ranke (*Volkmann's Sammlung Klinischer Vorträge*, No. 128) and other practitioners have already mentioned.

#### THE RUSSIAN ARMY IN ASIA.

DR. GEORGE STOKER, Chief of the Ambulance at Erzeroum, writes to us under date March 24th: The sanitary condition of this place and the health of the garrison are now becoming as serious a question to the Russians as it was to the Turks. The city is, so to speak, saturated with typhus, which decimated the Turkish ranks; and it is now ravaging the Russian ones. There are very few drains in the city, and nearly all of those that do exist are uncovered; the houses of the poorer inhabitants are totally unprovided with sewers of any kind, and the refuse of such houses is buried, during the winter, in the snow in front of the houses: now that the spring has set in, and the snow is melting, the state of affairs is easier imagined than described. At present, there are about 1,800 Turkish sick and wounded here; while, out of the 12,000 Russian troops comprising the garrison, there are about 3,000 in hospital, most of them suffering with typhus; the mortality is between 150 and 200 *per diem*. There is a dreadful scarcity of Russian doctors here, and a good many of those that do exist are ill from overwork or typhus. I am attending one now who, before having taken ill, was supposed to attend 286 of his battalion who were sick, the strength of the battalion being about 1,000 men. The fact is, that these soldiers are for the most part worn out with the hardships of a long campaign, and, once they are attacked with typhus, they have no strength to resist the fever, and die off. The Russian Sanitary Commission has been working here for the last two weeks; its attention has been especially directed to cleansing and disinfecting the grave-

yards. During the siege, between 18,000 and 20,000 bodies were interred within the fortifications. These were for the most part buried in large trenches, containing about 50 to 100 bodies, each covered over by only a very thin layer of earth; during the melting of the snow, the scanty covering was washed away from the graves, and a most repulsive stench and spectacle were the result. The graveyards were the common resort of the town dogs, who feasted there on human remains. The Commission has caused all these graves to be uncovered, and a layer of lime about eight inches deep to be placed over the bodies, and the graves then filled in to a depth of about three feet with dry clay. Thus it is hoped that the horrors of a plague or cholera will be averted. Our hospitals are going on very well. I send you statistics of operations performed in the Yeni Khan Hospital since February 6th. Out of twelve operations (six amputations of the forearm and wrist, and six of the leg)—eleven being for gangrene and one for necrosis—only one death occurred, in a case of amputation at the lower third of the leg. In two of them, gangrene spread, but it was afterwards controlled, and the patients eventually recovered; in one, the gangrene had destroyed all the muscles of the palm; I applied pure carbolic acid, and the wound granulated without any bad symptoms occurring. The dressing used was marine lint steeped in carbolic lotion; the ward where the patients were was fumigated each day with carbolic acid; no sutures were applied in any of these cases.

#### OPHTHALMIA IN DISTRICT SCHOOLS.

DR. JOSEPH ROGERS, reporting on the condition of the children at the Westminster Union Schools, Wandsworth Common, where ophthalmia had been somewhat prevalent of late, but is now succumbing under the effective measures adopted by the medical officer, stated that he had looked into all the matters connected with the preservation of the health of the children, and judiciously recommended an increased diet for them, that already in use being lower than those at the Marylebone Schools at Southall, North Surrey District School, Anerley, St. Pancras School, Leavesden, and the Newport Market Refuge School.

#### THE EURYDICE.

WHILST the relatives of the unfortunate officers and men who foundered with the *Eurydice* are watching with intense anxiety the measures taken to raise the vessel, and trusting that there will be for them the last melancholy satisfaction of attending at the Christian burial of their beloved ones, it may be useful to recall some of the circumstances of another similar naval historical event, of greater magnitude and of equally sad coincidences, the capsizing of the *Royal George*, at Spithead, in August 1782. On that occasion, a crew of three times the strength of the *Eurydice* were submerged. The Naval Hospital at Haslar was then, as it is now, the mortuary to which corpses were consigned for burial, but only seventeen out of so many arrived there; while the bodies of thirty-five, picked up afterwards in such a state of decomposition as to preclude identification, were buried in Kingston churchyard, near Portsmouth. How can this disappearance be best accounted for? Probably it may be that drowning in such sudden calamities is neither by exhaustion nor by cramp, but by suffocation, the result of water rapidly finding its way, in the few last gasps, into the lungs and into the stomach also; which, together with the weight of the sodden garments, renders the body specifically heavier than sea-water. Thus there is no tendency in it to rise again to the surface until, by decomposition, the tissues have become infiltrated with gases. But, where crustaceans abound, these gases escape through lacerations of the surface made by them, and buoyancy is thus precluded. In still waters of tideless harbours, in cold winters, corpses have been known to lie for seven or eight weeks on the muddy bottom, until the season of higher temperature has caused putrefaction to commence; and possibly, had there been any lacerations of skin, they would never have risen at all, but would have collapsed and undergone decomposition on the mud or oozy bed of the harbours. Both the *Royal George* and the *Eurydice* sank in tideways, with very

strong currents, which, from the first instant, swept constantly through the hatchways and open ports with searching effect; so it may be surmised that many unattached flexible masses lying in their course would be carried away and rolled into deeper waters or on to the shore. It is a remarkable feature in the *Eurydice* that so few of the watch on deck floated away from her, and that so very few corpses have been anywhere found. This may perhaps be explained on the suddenness of the struggle for life in the water, and the vortex created by the sinking ship taking them with her to the bottom; and the same reasons will apply *à fortiori* to the watch off duty and between decks. We think that, by calmly reflecting on such ideas, the minds of those who are now in eager expectation may be brought to a tone conducive to submission to many disappointments on clearance of the vessel; and this has induced us to comment on the distressing calamity that has overwhelmed so many households in grief.

#### ARMY MEDICAL OFFICERS' SERVANTS.

A CORRESPONDENT, referring to our remarks in the JOURNAL of April 20th, on the allowance granted by the War Office to medical officers in lieu of soldier-servants, observes that even if soldier-servants were allotted to medical officers, there would still be great difficulties to contend against under the present system of limited service in the army. He asserts that the combatant officers in regiments cannot now get good servants of the old type; that they are not to be obtained. The young unmarried men who chiefly fill the ranks of the army do not like to give up their spare time to service, which they would otherwise be spending in relaxation with their comrades; and, in many instances, if they consented to act as servants, would be constantly remanded to their regimental duties for some military fault or other. The working or private clothes bought for one man would not suit another, and thus the men would become sources of continual annoyance and expense. Under these circumstances, the only way in which the "servant difficulty" can be overcome is to increase the allowance to medical officers for a civilian servant; and every one must admit that the present grant of one shilling *per diem* is a very paltry and inadequate one for the purpose. In time of war, the medical, like other officers, must have military servants; no ordinary amount of pay would suffice to compensate civilian servants for the risks and discomforts, if not positive deprivations, to which they must inevitably be exposed under the circumstances of a campaign of any long duration.

#### PHYSICIANS' REWARDS.

THE *Levant Herald* of the 11th April publishes a letter from a correspondent, detailing an interesting ceremony which took place on the 8th April, on board the Italian mail-steamer, when, at the request of the Governor of Salonica, a party of medical officers visited the ship to bid farewell to Drs. Crookshank and Hope, and to express the best thanks of the Government for the valuable services the British National Aid Society had rendered to the Turkish wounded. Colonel Temple Bey, who accompanied the party, expressed his high appreciation of the zeal and energy of all the medical officers engaged under the Red Cross, and was the bearer of a letter containing similar testimony from the Governor-General. Dr. Crookshank was also the recipient of a testimonial of the most gratifying character, voted unanimously by his medical *confrères* at Salonica, which ran as follows. "We, the undersigned medical officers of the Salonica hospitals, beg to thank you and your colleagues, Drs. Hope, Lightfoot, and Jolly, for the valuable assistance, alike material and personal, you have rendered to the Turkish sick and wounded, in a time of extreme need. We are anxious to bear our testimony to the promptness with which you commenced your work on arriving in Salonica. We have marked your untiring assiduity, your unselfish devotion, and your earnest sympathy towards the numerous wounded committed to your care. We have admired the facility with which you surmounted those many incidental difficulties always found where wounded soldiers are accumulated. We desire to congratulate you on the brilliant success which has attended your efforts in your

operative treatment of the wounded. We cannot forbear to mention our warm appreciation of the judicious liberality, combined with economy, with which you have distributed the very valuable stores so kindly given by the British National Aid Society."

#### THE MARTIN MEMORIAL.

INSPECTOR-GENERAL W. C. MACLEAN has issued a circular, from the Royal Victoria Hospital, Netley, stating that, shortly after the death of the late Sir Ranald Martin, C.B., a meeting was held in London, to take measures to perpetuate the memory of this eminent military physician. Many of the leading members of the medical profession were present and took part in the proceedings; and it was determined to raise a sum of money sufficient to give a gold medal to be competed for, twice a year, by the candidates for commissions in the medical services of the British and Indian armies, and the Royal Navy, in the Army Medical School—the medal to be awarded to the candidate taking the first place in military medicine. A sum of money amounting to £361 16s. was accordingly subscribed. Suitable dies for the medal were prepared by Messrs. Wyon, the well-known medallists; and (after paying the cost of these) the money remaining was invested in the names of Sir William M. Muir, K.C.B., the Director-General of the Medical Department of the Army, and Professor W. C. Maclean, C.B., of the Army Medical School. Three medals have been given since the institution of this prize; but the trustees regret to say that, to enable them to go on giving a gold medal each session without touching the capital, a farther sum of £70 is required for investment. The trustees appeal to the friends of the late Sir Ranald Martin, and in particular to the medical officers of the three services—old Netley men—to assist them by subscriptions (limited in this country to ten shillings, and in India to five rupees) to carry out the original purpose for which the medal was founded. The above-named trustees will be happy to receive contributions.

#### CONVEYANCE OF THE SICK.

A CORRESPONDENT of the *Times* writes on April 23rd:—Every one will admit that the present system of conveyance of sick and injured persons to hospitals is very objectionable. It is not possible, of course, to calculate how far the spread of infectious diseases prevails through the employment of hired vehicles. In New York, an excellent system exists. It is the intention of the Order of St. John to make an effort towards introducing here a system of ambulances to meet this want, by establishing at certain places centres where vehicles can be despatched at a moment's notice to any district wherever an accident or case of sickness may occur. It is to be hoped that the public will lend a helping hand to a work which is so important for their welfare.

#### THE ST. JOHN'S AMBULANCE ASSOCIATION.

THE principal local centre of this Society yet established is at Woolwich, and there, as well as at Chelsea and Sevenoaks, classes for men and women are held weekly. A class for men is just completing its course at the Custom House; whilst at Paddington there is a class for ladies. Maidstone, Brighton, and Worcester, we are informed, are following in the same direction; and new classes are about to be opened at the Albany Street Barracks, the Duke of York's School, and at Lavender Hill, Hackney. At Paddington, too, a class for men is ready to commence training. The instruction is given by members of the medical staff in a popular and practical manner. At the termination of each course of lectures, which is dependent on the instructors, there is an examination, attendance at which is quite optional on the part of the pupils. Those who can pass to the satisfaction of the examiners receive a certificate to the effect that they are qualified to afford first assistance to persons injured by accident or otherwise. And at the recent meeting of medical authorities, it was resolved that the various hospital committees shall arrange to supply higher instruction to the certificated pupils of the Association. Not only has the St. John Ambulance Association a considerable guarantee fund ready for the outbreak of any war in which the British military forces may be engaged,

and a steam-yacht kindly placed at its disposal by the Marquis of Conyngham for the conveyance of its *personnel* and *matériel*, but the roll of the Society already includes the names of one hundred and twenty-seven persons qualified as physicians, surgeons, dressers, storekeepers, dispensers, nurses, and bearers, of whom seventy-two are willing to take service abroad, as a supplement, if necessary, to the Army Medical Department. Of eighteen surgeons on the list, eleven have seen active service in the field. The Association already possesses a few ambulance carriages of the best and newest patterns, and the excellent two-wheeled litter patented by the Order of St. John; and a larger number of useful stretchers and other ambulance necessities are being rapidly distributed throughout the kingdom. Sir Richard Wallace, Bart., M.P., has subscribed £500 to the guarantee fund of the Ambulance Association.

#### RESTORATION OF THE APPARENTLY DROWNED.

THE School Board of London have, on the application of the National Life Boat Institution, decided to instruct all their scholars, now numbering 111,000 children, in its important directions for the restoration of the apparently drowned. The leading principles of these directions for the restoration of the apparently dead from drowning are founded on those of the late Dr. Marshall Hall, combined with those of Dr. H. R. Silvester. No one can doubt the great usefulness of giving such instruction to the children. At the same time, it might with advantage have been delayed, as at this moment there is a considerable belief that Dr. Howard's method is an improvement on that of the two gentlemen previously mentioned. Dr. Howard has been for some time under a promise to contribute to these pages a report of the demonstrations of his method which he gave at the last annual meeting of the British Medical Association, but, like many other men, finds himself most busy when engaged in holiday-making, as his occupations during his stay in Europe prove too onerous to leave him time to fulfil this engagement.

## SCOTLAND.

#### THE MORTALITY STATISTICS OF GLASGOW.

DR. JAMES B. RUSSELL, the Glasgow Medical Officer of Health, has just issued the mortality statistics of that city for the past year. The population within the municipal boundary, estimated as at the middle of the year, was 346,921. Of deaths, there were 13,758, or 25 per 1,000; and of births, 21,179, or 38 per 1,000. The natural increase of population was, therefore, 7,421, or nearly 14 per 1,000. Of the great classes of diseases, the following is a list ranged according to the proportion in which they contributed to the total deaths: Consumption and acute diseases of the lungs, 5,285; nervous diseases of children, etc., 1,904; scarlet fever, measles, whooping-cough, croup, and diphtheria, 1,260; diarrhoeal diseases, 263; fevers, 262; small-pox, 11; and unclassified diseases, 4,773. The death-rate for the year was lower than the average for ten years—29.9 by 1.8; this being the lowest death-rate on record. On comparison with the eight "principal towns of Scotland", the mortality was exceeded by Paisley and Leith; and with the twenty "large English towns", by six, including Manchester, Liverpool, and Birmingham.

#### ABERDEEN UNIVERSITY.

THE ceremony of capping, in connection with the late medical graduation, took place on Thursday, April 24th, in Marischal College, Aberdeen; Dr. Pirrie, the Principal, presiding. The following were promoted to the degree of M.D.: R. R. Alexander, Hanwell Lunatic Asylum; Alexander Baird, Perth; R. S. F. Barnes, London; David Bower, Murrayfield, Edinburgh; Robert W. Burnet, London; James Cameron, Hendon, Middlesex; Charles Creighton, Cambridge; J. T. Crowden, Wisbech, Cambridgeshire; Charles Davidson, Coventry; D. P. Duirs, Dipton, Newcastle-on-Tyne; R. T. Hales, Holt, Norfolk; E. J. W. Hicks, London; H. J. Hott, Bromley, Kent; F. W.

Jackson, Broadstairs, Kent; F. H. Kyngdon, Sydney, New South Wales; Alex. McPherson, Haslingden, Manchester; R. J. Morice, Palmerston, South Australia; Wm. Morrish, Peckham, London; D. A. Patterson, Aden; J. M. G. Pirrie, Aberdeen; M. Poignand, Islington, London; J. Rodger, Aberdeen; W. T. Sheppard, Liverpool; James Simpson, Aberdeen; J. H. Simpson, Rugby; H. B. L. Smith, London; Henry Watson, Norwich; Robert Wharry, London; E. A. White, Malmesbury, Wilts; Alexander Williams, Tarland. The John Murray Medal and Scholarship was awarded to Alexander Milne Henderson as the most distinguished graduate of his year.

#### GLASGOW UNIVERSITY.

THE General Council of the University of Glasgow have elected the Duke of Buccleuch to the office of Chancellor, vacant by the death of Sir William Stirling Maxwell. It was stated at the meeting that, in order to take advantage of the Marquis of Bute's gift of £45,000 for the erection of the Central Hall of the University, a further sum of £25,000 would have to be expended, and an appeal was made for subscriptions. The library of the late Sir William Hamilton has been secured for the University of Glasgow by the liberality of twenty-one private gentlemen, each of whom had come forward and offered to give £100 for this object. This library is one of the most unique and perfect private philosophical libraries in Britain, or indeed in Europe.

#### VACCINATION.

At the Sheriff Court, Paisley, on the 25th ultimo, the Rev. John F. Potts, minister of the New Jerusalem Church, Glasgow, and residing at Mount Florida, was fined one pound and twenty-five shillings expenses, with the option of imprisonment for ten days, for refusing to allow his daughter, who had been born on July 30th, 1876, to be vaccinated. The defender explained that he refused from conscientious scruples, as it was his conviction that the operation did more harm than good.

#### CLINICAL EXAMINATION IN ABERDEEN.

A PROTEST has been lodged with the Senatus of the University of Aberdeen in reference to the clinical examination. The protest is signed by the whole of the gentlemen who graduated, and a good deal of strong feeling appears to exist on the subject; originating, in part at least, it is said, in the circumstances that among those who failed to pass in the clinical examinations—which are, of course, oral and not written—are several admittedly good students. These gentlemen's names are not, however, added to the protest, which has been promoted by those who passed and have graduated. The terms of the protest are as follows:

*"To the Venerable the Senatus of the University of Aberdeen,*

*"The Petition and Protest of the undersigned graduates of the University of Aberdeen against the examiners appointed by the aforesaid Senatus in Clinical Surgery, as after mentioned, humbly sheweth, that your petitioners complain of the manner in which the examinations in Clinical Surgery in your University were conducted by the examiners appointed by you, and in particular that the questions put to the different candidates differed in degree, and were unsatisfactory as a test, and that the more especially as regards the qualification for honours and merit. Your petitioners are persuaded that a different system should henceforth be pursued, and your petitioners humbly suggest that it would be well that you should recommend to the present examiners to give a greater variety of cases and cover more ground in their questions. And your petitioners will ever pray."*

#### IRELAND.

THE operation for ovariectomy was performed in two Dublin hospitals—the Coombe Lying-in and the Richmond—last week. The result in both cases was, unfortunately, unsuccessful.

A DEATH from small-pox has taken place at Drumsillagh, Cavan. The deceased had recently arrived from Dublin; and, it is supposed, had contracted the disease in that city.

WHOOPIING COUGH has been unusually fatal in Dublin during the March quarter, no less than eighty-two deaths having been recorded for this disease, against thirty-five in the preceding quarter.

#### MEASLES.

THIS disease has been very prevalent for a considerable time in various parts of Ireland; and although in Dublin during the first three months of this year, only about half the deaths occurred from that of the preceding quarter, yet the deaths registered (75) are above the average. In Belfast, for the same period, 42 deaths took place; in Cork, 49; and in Waterford, 65. In the last named town, measles with whooping-cough caused the deaths from the principal zymotic diseases to amount to the excessively high rate of 13.5 per 1,000 persons.

#### NURSES FOR THE SICK POOR OF BELFAST.

THE fourth annual meeting of the friends of the Society for Providing Nurses for the Sick Poor, was held last week in Belfast. This is a valuable organisation, and although recently established, has made satisfactory progress and performed a considerable amount of useful work by annually relieving a large class of sufferers. The objects for which the Society has been formed is to nurse the sick poor in their own houses; to give instruction in disinfecting and other sanitary matters; to teach the relatives of invalids the simple rules of nursing, and how to prepare food in a wholesome manner; also, to supply the nourishment that may be necessary for the recovery or well-being of patients in cases where they are too poor to procure it themselves. During the past year ending 1st March last, 607 sick persons were visited by the nurses, of whom 357 were sent by medical practitioners in the various districts allotted to the nurses. Each nurse visits the doctor of her district at the dispensary once a week, to receive his orders respecting old patients and to take new ones. Also, when necessary, she reports symptoms to him in any critical case. Among the patients thus attended to during the year, were many severe surgical cases, 161 consumptive patients, 22 cases of cancer, etc. During the twelve months, above 13,500 quarts of milk were given to the sick, besides beef-tea, arrowroot, eggs, and puddings; whilst beds, bedding, easy chairs, air-cushions, and medical appliances, were lent out when required. The expenses for the year amounted to £560; and by this sum, upwards of six hundred cases of suffering were relieved. The late Dr. Henry M. Johnston took a great interest in the Society; and by his will, a considerable sum of money has been placed in the hands of trustees, to be used as they may direct for the relief of the sick poor, the preference to be given to those suffering from phthisis and cancer, and living in those districts where his professional life had been chiefly spent.

#### PRESENTATION TO DR. GORDON OF BELFAST.

ON last Saturday, the past and present pupils, colleagues, and friends of Dr. Alexander Gordon, Professor of Surgery in the Queen's College, Belfast, presented that gentleman with an illuminated address and full-size portrait of himself. The address congratulated Dr. Gordon on the results of his professional labours for the past thirty-seven years, and in flattering terms referred to his work as an independent investigator, an ingenious inventor, and an original thinker; and assured him of the high regard in which he was held on account of his discoveries in surgery, his intimate knowledge of the whole field of medical science, and his great success in teaching and in instilling into the minds of his pupils that spirit of thoroughness which eminently characterised his own investigations. His researches on fractures and dislocations had gained for him imperishable laurels in those departments of surgery, and secured for him, years ago, the highest place as an authority on fractures of the clavicle and radius, the Gordon splints being now in use wherever enlightened surgery prevails. They begged to present the oil portrait to the Queen's College, as a slight token of their appreciation of his labours in raising its School of Surgery to the high position it at present occupies. Dr. Gordon having replied in appropriate terms, and a vote of thanks having been passed to the

President of the College for presiding, the proceedings terminated. The portrait, which has been placed in the Examination Hall, is by Mr. Hooke, and is stated to be a very accurate likeness, and to be possessed of great artistic merit. Dr. Gordon is represented as lecturing, holding in one hand a fractured bone, to which he is directing the attention of the class, whilst on a table close by there is delineated a fracture put up with Gordon's splints. There will be a copy, half-size, presented to Mrs. Gordon when completed.

#### THE DUBLIN ORTHOPÆDIC HOSPITAL.

A SPECIAL meeting of the friends and supporters of this well managed institution was held last week to consider the propriety of purchasing premises adjoining the hospital, with the view of enlarging it. The Right Hon. the Lord Mayor was in the chair; and, from the *ad interim* report presented by the House Committee, it appeared that both the demands on the accommodation of the hospital and the support it was receiving were increasing. They, therefore, recommended the purchase or hire of the adjoining house, a large building containing seventeen rooms, the owner of which had expressed his willingness to sell. Want of funds, however, stood in the way; but finally the House Committee were empowered to purchase or hire the premises, as they might deem expedient.

#### THE SMALL-POX EPIDEMIC.

IN consequence of the serious proportions the epidemic has assumed in Dublin, the Guardians of the North Dublin Union have, thanks to the prompt action of their chairman, prepared sheds at Glasnevin for the reception of patients and convalescent cases. These sheds are exceedingly well situated, being quite apart from the city although easily accessible. Hitherto, most of the cases of small-pox have been at the south side; but latterly, the disease has made its appearance on the north side also. Already, both acute and convalescent cases have been admitted to these sheds, and a medical officer—Mr. J. W. Mallen—appointed to their charge. The regular accommodation provided for small-pox patients by the hospitals proper, has in most cases been already exceeded. In two of these institutions, the disease has, we regret to say, spread to other patients within their walls. The cases of small-pox under treatment in the six principal hospitals on the 20th ult., show a considerable increase on the number for the week ending on that day. They amounted to 203, or 34 more than on the previous Saturday; 110 cases were admitted during the week, and 8 died.

#### WOOD-PAVEMENT FOR HOSPITALS.

CERTAIN streets in which some of the Dublin hospitals are situated being lately prepared for paving, efforts have been made, in the interests of the patients, that wood-pavement should be laid before them instead of the noisy stone. The Committee of the Corporation having charge of the streets, have heretofore not felt warranted in recommending the adoption of wood-pavement, in consequence, it would seem, of its greater expense, and from want of satisfactory evidence as to its durability. An opportunity has accordingly been lost, in one case at least, of affording an incalculable boon to the inmates of an hospital—Mercer's—which immediately abuts on a street through which there is a heavy traffic day and night, and which receives a large number of accident and other serious cases. Attention, however, has again been drawn to the subject in connection with the Rotunda Hospital. The auxiliary portion of this hospital, viz., that in which ovariotomy and other important operations are performed, and which provides accommodation for "chronic" cases, is only six feet from the street. Patients have complained much of the noise from even the ordinary pavement; and as the street in which it is situated is being at present paved with stone, it is to be hoped that the Committee will accede to the strongly expressed opinion of the medical staff of that institution, supported as it has been by general professional opinion, and substitute wood-pavement, even if for no more laudable object than an experimental trial.

#### MEDICAL TEACHING IN THE UNIVERSITIES.

It was the late Dr. Parr, we believe, who rose up and said, "I will confound mine enemy in a pamphlet"; and, in modern history, the winged words of these *libelli* have often done greater things than heavier artillery. By pamphlets despotisms have been tempered; by Tract 90 the face of Oxford and of England was changed; and by pamphlets and post-cards the policy of our present Government has been shaken. We do not apologise, therefore, for keeping silence until the first reading of another recent pamphlet is over, and until its readers and our own are prepared to express some matured opinion upon its subject and contents. The subject of medical education at the old universities has indeed been discussed in our columns with vivacity, and by one correspondent at least with something more than vivacity; nor have we forbore to take our own part in this controversy. Moreover, but a few days have elapsed since the Board of Medical Studies at Cambridge have published their recommendations to the University: recommendations the result of eighteen months' most serious consideration, which, if carried out, will lead to a revolution in its medical teaching. It has been lately said that Cambridge is less given to thinking aloud than her sister (Professor Jack, *Fortnightly Review*, April 1878), and these important proposals have been developed in silence. Dr. Michael Foster's pamphlet *On Medical Education at Cambridge*, though not written at the suggestion, nor even with the connivance, of the Board of Medical Studies, is, then, most happily timed, and deals with this matter in a masterly and forcible way, and with the hand of one who has been long enough engaged in active teaching at Cambridge to know its work and powers, and yet not committed to it so early in life as to have lost his freshness of observation. Whether we permit ourselves to agree with the author throughout, or whether we restrain our acceptance of his arguments, we find, at any rate, that he commands our attention and our serious thought.

No less a question is raised by Dr. Foster and by our own correspondence than that of the whole use and meaning of an university: to wit, are the old universities centres only of general and liberal culture, or are they to contain also in themselves the means of special and of technical education? The word technical education has been used of late to signify practical education or the cultivation of the hand and eye; but it more properly means education in an art. Are the old universities, that is, to complete the general training of the mind only, or are they to adapt their sons to professions and handicrafts? During most of the present century, it has been held by those in power that the former function alone is theirs. We undertake, they say, to make you a scholar and a gentleman; it is not for us to aid in the conversion of your brain into a bread-winning machine. They complain of the utilitarian spirit of the age:

"hæc . . . sæcula . . . sunt ingrata camænis,  
Ipse licet venias musis comitatus, Homere,  
Si nihil attuleris, ibis, Homere, foras."

They may admit that a man must live, and that it is not ill indeed that some of their children throw themselves into the world and hasten after riches as churchmen, lawyers, physicians, or engineers. The life of the world may require them, but the highest life is devotion to pure knowledge and contentment with the endowment of daily bread. None can hear this saying without emotion; it appeals to that which is highest in man; but rough experience has thrust it aside, and, like many another noble dream, its *désillusionnement* comes with years. The hands are the hands of the modern professor, the voice is the voice of the cloister.

Dr. Foster points out very clearly the outcome of this ascetic doctrine. He says (page 21): "The presence in the University of a strictly professional and technical element would be, as indeed it in past times has to some measure been, a direct benefit of no small amount. From the very constitution of the human mind, the pursuit of knowledge for its own sake, when carried on by means of any complex organisation, is apt to become degenerate. The individual inquirer is, in most cases, preserved by the salt of his own enthusiasm from decomposing influences, but not so societies. There is always a tendency in an institution devoted to pure learning either to exaggerate the repose which the pursuit of knowledge needs until it becomes absolute stagnation, or, on the other hand, to fret the wholesome discussions which stimulate inquiry into idle disputations about trifles. Where the spur either of some practical object or of an irresistible personal impulse is wanting, the means always was the chance of being honoured as much as, or even more than, the end. The practical man to whom the end is all

and all, and the means only a means, is in such an assembly a corrective of almost inestimable value. And the University in this respect obeys the law of other societies. Granting that there is amongst us a very large amount of rightly directed intellectual activity, we must all confess to the existence of a tendency to academic repose broken by academic wrangling. Speaking for my own line of work, I feel convinced that the future study of physiology will suffer greatly at Cambridge, unless it be kept straight by the presence of a practical medical element; and what is true of one branch of learning is probably true of all, as it certainly will be to the benefit not only of the medical profession, but also of all other technical occupations, that the men employed in them should be brought up side by side with those to whom abstract truth or general culture is all in all."

We give this extract in full, in the conviction that herein lies the root of much difference of opinion concerning the modes and means of university education, nor could any words of ours add to the force of it.

But, it may be objected, granting the development side by side of research and of applied science is wholesome for both, yet neither Oxford nor Cambridge can, in the nature of things, offer adequate instruction in the professions. We have to consider this objection only in so far as it concerns the profession of medicine. To begin, such was not the forecast of the founders of medical chairs at various dates in these universities. When some of them were founded, surgery was scarcely even an empirical art; but, in medicine, a Regius Professorship was founded in both universities by Henry VIII, and the medical endowments of Dr. Cains were made a few years later; the Lee's Readership at Christchurch was founded in 1755; the Aldrichian Professorship of Medicine in 1803, and the Downing Professorship in 1800. Various as these dates are, it may still be urged that circumstances have much changed even since the last of them, and that use of them became impossible, which before was possible and desirable. Now, it would appear, as regards Oxford, at any rate, that whatever holds good at present has held good in the past; for we suspect that, since Oxford was a foundation, it has never bestowed more than ten medical degrees in any one year; it is not true, then, that men have deserted the old universities for the new, as expenses increased as tests became relatively more galling, and as locomotion became more easy. The truth is rather that Oxford and Cambridge fail, and have always failed, to offer the inducements to students of medicine which are offered by other schools. At neither university has a school of medicine ever been duly organised, and now it is loudly asserted, first, that the means for such an organisation do not exist, or, secondly, if they exist in a measure, that the results of such an organisation would not justify the outlay, or be worthy of the universities or of the nation.

If we admit that a wealthy university should be the seat of universal knowledge, and if we admit that abstract and applied learning should, for the sake of each, develop together, we must carefully examine these assertions, and the authority upon which they are made. In respect of authority, we find a curious division. Oxford, as a whole, supports them, and Cambridge, as a whole, denies them. The Regius Professor of Medicine at Oxford supports them; the Regius Professor at Cambridge denies them; the Linacre Professor supports them; the Trinity Praelector denies them. Indeed, the Professor of Anatomy of Cambridge is the only Cambridge authority who supports them, and yet he would not only teach pathology at Cambridge, but would initiate men there in practical medicine and surgery, *e.g.*, in bandaging, manipulation, stethoscopy, and general principles; in a word, he would detain men until their second M.B., but thinks any further teaching in midwifery, medicine, and surgery would be a third-rate affair. Dr. Foster's argument, that medical education at Cambridge might be complete and excellent, is therefore supported by every competent authority in Cambridge save one, and even Dr. Humphry is but a partial dissident. The curiously opposite view taken at Oxford is too well known for repetition; but, to show how widespread it is, we will pass over these well known opinions of Professors Acland and Rolleston to add, of our own personal knowledge, that the views of these distinguished men are largely shared by their juniors.

Authorities being thus divided, we must examine the assertions for ourselves. The question is one of so great importance that we do not hesitate to give up a large part of our columns to the discussion of it; but, on the other hand, we are bound, by heavy demands upon our space, to be brief where brevity is possible. After close inquiry, the arguments against the organisation of schools of medicine in Oxford and Cambridge seem to revolve themselves about one only; *viz.*, the allegation of the inadequacy of the local hospitals. Before entering into this, let us agree that an Oxford or Cambridge training is invaluable to a physician or surgeon, whereupon we may presume that the longer the University can retain its medical pupils the better, if they

are working to advantage. Now, any difficulty of teaching clinical medicine or surgery does not affect the teaching of the earlier subjects: of human anatomy, of physiology, of pathology, and of elementary medicine and surgery. It is far from convincing to reply that the facilities for such teaching will spring up where the teaching is needed; and that the absence of them in Oxford and Cambridge is proof of a want of demand. On the contrary, such growth in Oxford has been deliberately crushed, and foundations like the Lee's Readership have been so misapplied\* that we cannot but think some remedy at law must be possible. We shall carry our readers with us when we say that human anatomy, physiology, and pathology, for instance, could be taught far better at Oxford and Cambridge by the occupants of well endowed chairs, than in London by the young physicians who use such chairs only as means to other ends. Oxford, in her desponding way, tells us that neither for anatomy nor for pathology can material be had. Surely, this is the argument, not of a vigorous but of a spiritless community. Oxford is surely as well able to secure material as Cambridge; and Dr. Foster (page 23) foresees no difficulty in obtaining materials for pathology, and, from personal knowledge of Dr. Bradbury, we may venture to assert that, during the four or five years in which he has lectured upon pathology in Cambridge, he has had plenty of material. Surely, if not autogenetic, it can be imported, and the neighbouring asylum and workhouses may always be laid under tribute. As to subjects for dissection, we may say that nearly all teachers are agreed that far too much time is taken from physiology to be given to topographical anatomy; but, even if we allow the fullest measure to anatomy, we deny that the difficulty of obtaining subjects is greater at Cambridge or Oxford than in every other school. But such material will not come to those who sit and sigh for it. We know a good deal about the dissecting-room at Cambridge, and that the forty or fifty men at work there complain of no lack of material. The distinguished professor of anatomy took care that no difficulties should stand in his way. By slow and careful but determined efforts, Dr. Humphry won to his side the guardians of unions and the magistracy, and so gained the unclaimed over a radius of many miles, nor did he rest until he obtained that alteration of the Anatomy Act which enables teachers to preserve subjects during the summer months. If the hospitals be defective, their deficiency up to this point is a positive advantage; for, as Dr. Foster says (page 13), "some men flit from the dissecting-room to the hospital, and from the hospital to the physiological laboratory; and they cannot find time to grasp any one of the three subjects, on account of the pains they are taking to lay hold of the other two. In the end, they find they have learned none of the three". Nothing can be truer or more needed than this stricture; but we hasten to add that, at Cambridge, it is wholly undeserved; undeserved, that is, so far as tutorial wishes and admissions are concerned.

Up to a certain point, then, the absence of a clinical hospital is even a gain, and the Board of Medical Studies have recommended to the University of Cambridge the endowment of a Professorship of Pathology, without right to practise, with a stipend of £700 *per annum*, and with a demonstratorship and laboratory. In Oxford, a professor of human anatomy should likewise be founded out of the Lee Fund.† We presume that, like the Trinity Praelector in Cambridge, the Magdalen lecturer would take charge of physiology in Oxford. *Materia medica* and therapeutics form the subjects of the Downing professor, and a like professor will be needed in Oxford, if the latter university is not to be deprived by her sister not only of all her medical students, but also of those students of science who intend to graduate in medicine.

Against the teaching of medical studies up to this point, and against the foundation and probable success of such chairs—chairs only to be rivalled by those in the University of Edinburgh—there is, so far as we know or can learn, but one more argument. It is said that the best men will not take posts which will not lead to practice. Now, we think such chairs ought not to lead to practice, and we should only permit the professors of medicine and surgery to practise, because we think their teaching would suffer in vigour and variety if they were restrained to hospital experience. We think that the counter-attractions of increasing practice are a great injury to the teaching in the London schools, and are of opinion, therefore, that the university professors should have stipends which, with a proportion of fees, would give them clear incomes of £1,000 *per annum*. Now, is it true, as even Dr. Foster fears, that the very best men would decline these

\* *Ibid* BRITISH MEDICAL JOURNAL, January 19th, 1878, page 95.

† The recommendations of the Oxford Commission are published in the *Times* for April 28th. A friendly critic will call them tentative; a hostile feeble. They seem to us even less adequate than the reported resolutions of the meeting of Oxford medical graduates lately held in London.

chairs? Dr. Foster suggests that they might be held for a few years by men who through them would seek to make reputations commanding enough to secure practice in case of their removal to large towns in their later years. Surely, those who speak thus largely overrate professional incomes and underrate the toil and sacrifices by which such incomes are won. A professorship even of £800 *per annum*, with a laboratory and demonstrator, obtained, say, at the age of 30, would at least compensate the student, who, to the love of research, might sacrifice the privilege of waiting in an expensive house on no income to speak of till the age of 40, of then taking his luck of public favour, and of making, perhaps, some four or five thousand a year until his health and vigour fail. Nay, is not one thousand *per annum* likely to be a strong attraction to those more ardent inquirers who would prefer an assured, if comparatively moderate, income, with leisure for work and for academic and social delights, to a scramble after five or ten times the amount in fees: fees gained at the sacrifice of private study, of teaching opportunities, of leisure, of vacation, and of all the amenities of life! We do not know what such men as Dr. Lockhart Clarke and Mr. Parker would say on this matter; but we should be much surprised to find them against us.

[To be continued.]

### ARMY MEDICAL SERVICE.

THE following letter has been addressed by the Right Hon. Colonel Stanley, Secretary of State for War, to Mr. Ernest Hart, as Chairman of the Parliamentary Bills Committee of the British Medical Association.

“War Office, 27th April, 1878.

“Sir,—In considering the valuable reports which have been received from the several medical teaching bodies on the circumstances which tend to deter eligible candidates from coming forward for the Army Medical Service, the Committee appointed to inquire into the subject would be greatly helped if they had before them a trustworthy estimate of the average earnings, under ordinary circumstances, of medical practitioners in civil life. I am, therefore, directed by Secretary Colonel Stanley to request that, on behalf of the British Medical Association, you will favour him as soon as possible with an estimate, on the enclosed form, of the average earnings in question.—I am, sir, your obedient servant,

RALPH THOMPSON.”

*Estimate of the Average Earnings of a Civil Medical Practitioner.*

### HARVEY TERCENTENARY MEMORIAL FUND.

THE additions to the Fund during the past week amount to nearly £100, and include the following contributions. From the Town Council of Folkestone, fifty guineas; the Obstetrical Society of London, twenty-five guineas; and the North of England Branch of the British Medical Association, five guineas. We are asked again to request the members of the profession who have not hitherto contributed to this object to kindly send their donations at once to either of the hon. treasurers (Sir George Burrows, Bart., or Mr. Prescott Hewett), or to either of the hon. secretaries (Mr. Geo. Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone), or to pay them into the account of the Harvey Tercentenary Memorial Fund at the Western Branch of the Bank of England, Burlington Gardens, London, W. Subscriptions from five shillings upwards will be very acceptable.

### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AT a meeting of the College on April 25th, a portrait of the late Dr. P. M. Latham was presented by his daughter, and thanks were voted. A communication from Liège was read, stating that a public ceremony would be held in June, when a bust of Professor Schwann was to be placed in the University Museum, and inviting some representative of the College to be present.

## ASSOCIATION INTELLIGENCE.

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE annual meeting of this District will be held at Canterbury, on May 16th, at 1.30 P.M.

It is proposed that after the meeting the members will visit the County Asylum at Chartham, permission being kindly afforded by Mr. R. Spencer, the Medical Superintendent.

WM. KNIGHT TREVES, F.R.C.S., *Honorary Secretary.*

Margate, April 29th, 1878.

### METROPOLITAN COUNTIES BRANCH.

A SPECIAL General Meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesday, May 15th, at 4 P.M.

1. To receive and (if thought proper) to adopt an amended code of By-laws for the Branch.

3. To consider the Bills for the Amendment of the Medical Act (1858) now before Parliament.

An Ordinary Meeting of the Branch will be held at the same place on Wednesday, May 22nd, at 8 P.M., when papers on Vaccination will be read by Dr. E. C. Seaton and Dr. J. Greene of Birmingham.

Further particulars will be given in the circulars convening the meetings.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*  
W. CHAPMAN GRIGG, M.D. }

57, Doughty Street, W.C., May 2nd, 1878.

### NORTH OF IRELAND BRANCH.

A MEETING of this Branch will be held on Friday, the 17th instant, at 12 o'clock, noon, in the Board Room, Belfast Royal Hospital.

JOHN MOORE, M.D., *Honorary Secretary.*

Belfast, May 1st, 1878.

### PROCEEDINGS OF THE COMMITTEE OF COUNCIL.

AT a meeting of the Committee of Council, held at the Freemasons' Tavern, Great Queen Street, London, on Wednesday, April 17th, 1878: Present, Dr. R. W. FALCONER (President of Council), in the Chair, Dr. E. Wilkinson (President), Mr. W. D. Husband (Treasurer), Dr. T. Clifford Allbutt, Mr. Alfred Baker, Mr. J. Wright Baker, Dr. M. M. De Bartolomé, Dr. Louis Borchardt, Mr. Callender, F.R.S., Dr. Alfred Carpenter, Dr. Chadwick, Dr. J. W. Eastwood, Mr. W. A. Elliston, Dr. B. Foster, Mr. R. S. Fowler, Dr. E. L. Fox, Dr. W. C. Grigg, Dr. C. Holman, Mr. Arthur Jackson, Dr. D. J. Leech, Mr. E. Lund, Mr. Frederick E. Manby, Mr. Frederick Mason, Dr. Edwin Morris, Mr. R. H. B. Nicholson, Dr. Charles Parsons, Dr. Procter, Dr. Edward H. Sieveking, Dr. A. P. Stewart, Dr. W. F. Wade, Dr. E. Waters, and Mr. C. G. Wheelhouse:

The minutes of the last meeting and of the special meeting were read and found correct, with the exception of recording the vote upon the female question as unanimous at the special meeting of the Committee of Council, which was amended.

Read letter of apology for non-attendance from Dr. Duffey.

Read letter from Mr. George Stanger, asking for support, together with the opinion of Mr. Day, Q.C., in reference to the case of the Apothecaries' Company v. Shepperley.

Resolved: That under the circumstances of the case, the sum of £25 be voted towards the expenses of the litigation in the cause of the Apothecaries' Company v. Shepperley.

Read letter from Mr. G. Eastes, Honorary Secretary to the Harvey Tercentenary Memorial, asking for a grant in aid of the funds of the memorial.

It was moved:

That the sum of £25 be granted for the promotion of the Harveian Memorial.

The motion having been put from the Chair, the same was declared to be lost.

Read letter from Mr. Napper, Secretary to the West Surrey District of the South-Eastern Branch, forwarding resolution, of which the following is a copy:

"That in the opinion of this meeting the admission of ladies to the membership of the British Medical Association is not desirable."

Similar resolutions were also read from Dr. Eytton Jones, of the North Wales, and Dr. Shettle, of the Reading Branches.

Resolved: That the one hundred and fifteen candidates for admission whose names appear on the circular convening the meeting be elected members of the Association.

The minutes of the Journal and Finance Committee of to-day's date were read, and also of the Subcommittee of the Journal and Finance Subcommittee.

Resolved: That the minutes of the Journal and Finance Committee of to-day's date, together with the minutes of the Subcommittee of the Journal and Finance Committee, be approved, and the recommendations carried into effect.

The minutes recommended that tenders be obtained from five builders for the alteration of the premises in the Strand, and that the quarterly accounts be paid.

Resolved: That the financial statement for the year ending December 31st, 1877, be approved, adopted, and published in the JOURNAL (see page 625).

Resolved: That the President of Council, the President, and Dr. Foster be appointed a Subcommittee to draw up the Annual Report.

Dr. Carpenter, the Chairman of the Committee appointed for obtaining legislative restrictions for habitual drunkards, brought up the report of that Committee of to-day's date. The minutes contain a letter from the Home Secretary stating his inability to receive the deputation in consequence of a press of business; also a recommendation from the Committee that the Home Secretary be urged to receive a deputation.

It was moved:

"That the minutes of the Committee for obtaining legislative restrictions for Habitual Drunkards, of to-day's date, be approved and the recommendations carried into effect."

Whereupon an amendment was moved:

That the minutes of the Committee be approved; but that a written statement, instead of a deputation, be sent to Mr. Cross, the Home Secretary, as requested by him.

The amendment having been put from the chair, the same was declared to be carried.

Read letter from Dr. Moore of Belfast, with copy of by-laws of Belfast Branch.

Resolved: That, in accordance with By-law 40, the North of Ireland Branch be recognised as a Branch of the British Medical Association.

Resolved: That the Committee of Council desire to welcome very cordially the North of Ireland Branch as an important addition to the Association, and they trust that it may be the means of extending the Association in the North of Ireland, and also of increasing the friendly intercourse of the Irish with the English and Scotch members of the profession. The thanks of the Association are hereby given to Dr. Moore and others for their great assistance in founding the Branch.

Also from Mr. Gayleard, of Jamaica, together with the by-laws of the Jamaica Branch:

Resolved: That, in accordance with By-law 40, the Jamaica Branch be recognised as a Branch of the British Medical Association.

Resolved: That the Committee of Council welcomed with great pleasure the first Colonial Branch of the British Medical Association.

Resolved: That a Subcommittee be appointed to consider the various by-laws now placed before the Committee of Council, consisting of the President of Council, Dr. Wade, Dr. Allbutt, Dr. Leech, and Dr. Parsons.

It was moved:

"That the questions now submitted to the Committee regarding the privileges of lady members, which have been approved by Mr. Upton, be submitted to counsel in accordance with the instructions of the General Meeting of the 2nd instant."

"That the questions relating to the privileges of the female members of the Association be referred to Mr. Bosanquet, of the Oxford Circuit, for settlement, and, when settled, they be referred to Mr. Benjamin, Q.C., for his opinion."

Whereupon an amendment was moved:

That the subject be referred to a Subcommittee, consisting of the President of Council, Dr. Chadwick, Dr. Sieveking, Dr. Wade, Dr. Parsons, Dr. Borchardt, to which was subsequently added the name of Dr. Holman, with power to act in the matter.

The amendment having been put from the chair, the same was declared to be carried.

Read: Resolution from the Metropolitan Counties Branch, of which the following is a copy:

*Extract from Minutes of Meeting of Council of Metropolitan Counties Branch, held January 26th, 1878.*

"Resolved: That the Council of the Metropolitan Counties Branch beg to suggest to the Committee of Council of the British Medical Association that, in making arrangements for new premises, provision should be made for a central reception-room for the members of the British Medical Association."

It was moved:

That the consideration of the subject of the provision of a reception room in London be referred to the Premises Subcommittee.

Whereupon an amendment was moved:

"That the consideration of this question be deferred for future discussion."

The amendment having been put from the chair, the same was declared to be lost.

Whereupon a second amendment was moved:

"That the Committee of Council are unable at the present to entertain the question of providing a reception room in London for the general members of the Association, but, as soon as the business premises are in successful operation, the Committee of Council will be prepared to consider—first, financially, whether the funds of the Association can afford such an annual outlay; and, second, whether such a reception room would be a sufficient advantage to the provincial and distant members as to induce the Committee of Council to recommend the scheme for adoption."

The amendment having been put from the chair, the same was declared to be carried.

It was then proposed as an amendment:

"That the Committee pass on to the next business;" which was declared to be carried.

Read communication from Mr. R. Middlemore, Birmingham, offering £500 to found a prize to be awarded every three years to the author of the best essay on the scientific and practical value of the improvements which have taken place in ophthalmic medicine and surgery.

Resolved: That the warmest thanks of the Committee of Council of the British Medical Association be forwarded to R. Middlemore, Esq., of Birmingham, for his very liberal donation of £500 for the foundation of a triennial prize, to be awarded for the best essay on the scientific and practical value of the improvements which have taken place in ophthalmic medicine and surgery, and that it be termed the Middlemore Prize.

Resolved: That a grant of £25 be made to the Manchester Subcommittee of the Out-Patient Reform Committee towards the expenses of procuring the information from the various provident dispensaries in Manchester.

Resolved: That the thanks of the Association be given to Dr. Waters for the promptness of his action in the matter of the Medical Reform and the Medical Acts Amendment Bill now before Parliament, and that he be reimbursed the amount that he has expended.

## HOSPITAL OUT-PATIENT REFORM COMMITTEE.

THE following extracts from the Minutes of Proceedings have been forwarded to us for publication.

At a meeting of the Committee appointed at the Annual General Meeting of Members at Manchester, August 10th, 1877, held at the Office of the Association, October 9th, 1877—Present: Mr. TIMOTHY HOLMES (in the Chair), Dr. Borchardt, Mr. Nelson Hardy, Dr. Robert Lee, and Dr. Joseph Rogers.

Read resolution of Annual Meeting, of which the following is a copy:—

"That a Committee, consisting of the following gentlemen, be appointed, with full authority to use the influence of the Association to procure such changes in the administration of out-patient relief at hospitals as they find necessary, and that the working of the present system of Provident Dispensaries in Manchester be carefully investigated and reported upon, viz.: Dr. Eason Wilkinson, Dr. A. P. Stewart, Dr. Alfred Meadows, Mr. T. Holmes, Dr. J. R. Lee, Dr. Joseph Rogers, Dr. Ford Anderson, Mr. Nelson Hardy, Dr. Brierley, Dr. Haddon, and Dr. Borchardt."

Read letter from Dr. Brierley, of which the following is a copy:—

"City Road, Manchester, October 8th, 1877.  
"Sir,—I regret that I cannot attend the meeting to-morrow of the Committee of Out-door Hospital Reform. It seems to me the Provident System is that by which we shall best remedy existing evils. Careful investigation into all applications for medical aid should be made by a paid official. It is not necessary that Provident Dispensaries be supplied before such inquiry is made into the circumstances of patients, for we have proved here that a very small percentage of those refused at the free go to the provident society. The conclusion, of

course, is—they seek aid from an ordinary practitioner, which is the most whole some effect one could wish, from watching the cases seeking relief for nothing. I have already said the scheme has utterly failed here. This is no fault of the principle, but bad management. There is an entire want of harmony between the profession and the public, which is a great obstacle in the working of the scheme.—I remain, yours,  
"F. Fowke, Esq."

"JAMES BRASSEY BRIERLEY."

Moved by Mr. HARDY, seconded by Dr. ROGERS, and

Resolved: That Dr. Eason Wilkinson, Dr. Brierley, Dr. Haddon, and Dr. Borchardt be appointed a Subcommittee to investigate the question of the working of the Provident Dispensary System in Manchester, and to report to this Committee at a future meeting:

1. Whether there is any evidence of improper cases admitted to the benefits of the Institution.

2. Whether the working of the Institutions has proved satisfactory, (a) to the medical officers of the Institutions, (b) to the medical profession at large in Manchester.

3. What has been the effect on the Free Charities which co-operate with the Provident Dispensaries, and on those which do not.

4. What relations prevail between the Provident Dispensaries and Sick Clubs.

5. Whether the working of Provident Dispensaries is satisfactory to their lay members.

6. What is the present system of Out-door Poor-law Medical Relief in Manchester, and how does it affect the Provident Dispensary System.

Resolved: That the Subcommittee be requested to give information upon the foregoing questions, and any other that they may find desirable.

Resolved: That a statement be prepared to lay before the Court of Aldermen, and the Colleges of Physicians and Surgeons.

Resolved: That Mr. Hardy and Dr. Lee be requested to draw up a statement to lay before the Court of Aldermen and the College of Physicians and the College of Surgeons, and to forward it to the Chairman.

At a meeting, held on Thursday, November 29th, 1877—Present: Mr. TIMOTHY HOLMES (in the Chair), Dr. Ford Anderson, Mr. Nelson Hardy, Dr. Robert Lee, Dr. Joseph Rogers, and Dr. A. P. Stewart: The minutes of the last meeting were read and found correct.

Read letters of apology for non-attendance from Dr. Eason Wilkinson and Dr. Brierley.

Read letter from Charity Organisation Society, asking that the petition to the Court of Aldermen be deferred till after a deputation to the London Hospital Committee from the Charity Organisation Society, and asking for the assistance of the British Medical Association.

Resolved: That the co-operation of the Committee with the Charity Organisation Society in the matter be given as far as possible.

The statement of Mr. Nelson Hardy and Dr. Robert Lee was then considered; and, after a few alterations, was adopted.

Resolved: That the Secretary be instructed to write to the Court of Aldermen, requesting to be informed when it would be convenient to them to receive a deputation relative to the management of the City Hospitals.

Resolved: That Mr. Ernest Hart be invited to accompany the deputation to the Court of Aldermen.

At a meeting held on Wednesday, the 9th day of January, 1878—Present: Mr. TIMOTHY HOLMES (in the Chair), Mr. Nelson Hardy, Dr. Robert Lee, Dr. A. P. Stewart, and Dr. Eason Wilkinson.

The minutes of the last meeting were read and found correct.

The Secretary reported that, in reply to this application to the Court of Aldermen, the following letter had been received.

"Guildhall, E.C., 9th January, 1878.

"Sir,—In reply to your communication of the 2nd inst., I have to inform you that, should your Committee desire to approach the Court of Aldermen, it must be by petition, to be presented by a member of the Court of Aldermen, and of which notice must be given at this office three clear days before the Court, and the signature of the member who will present it must be endorsed thereon. I enclose form of petition, in case your Committee desire to proceed in the manner above indicated. At the same time, so far as I am able to understand the Committee's object, it is right I should state that the Court of Aldermen have no jurisdiction in the matter.—I am, sir, your obedient servant,  
"JOHN P. MORTON."

"To the General Secretary, British Medical Association,  
36, Great Queen Street, W.C."

And in consequence a petition had been prepared, of which the following is a copy.

"To the Right Honourable the Lord Mayor and Court of Aldermen.

"The humble petition of the undersigned representative members of the British Medical Association, a body numbering over seven thousand members,

"Sheweth,—That, on behalf of that Association, we desire to

ask the assistance of your Right Worshipful Court in our endeavours to procure a reform of certain abuses which have crept into the administration of the large metropolitan hospitals, particularly as regards their out-patient departments. We need hardly remind you that after the suppression of the 'religious houses' by Henry VIII, the care of two of the largest of these hospitals—namely, St. Bartholomew's and St. Thomas's—was specially confided to the authorities of the City in response to the petition of Sir Richard Gresham, Lord Mayor, who pleaded for the poor, needy, sick, and indigent persons lying in every street, and undertook on the part of the City that if their petition was granted, these sick and indigent persons should be 'refreshed, maintained, and healed of their diseases, frankly and freely, by physicians, surgeons, and apothecaries'. We are fully aware that these hospitals have ceased to be so directly under the control of your Right Worshipful Court as they once were; but we cannot help noticing that whenever any such important step as the election of a Treasurer to one of these Royal Hospitals has to be taken, your influence, as forming a large portion of the body of Governors, has a most important share in deciding the result (as in the recent instance of St. Thomas's Hospital); and we therefore do not suppose that you would desire, if you could, to divest yourselves of all responsibility for the management of these hospitals.

"The two errors in the administration of out-patient relief at hospitals, to which we desire to draw your attention, have arisen, as it seems to us, through a disregard of the undertaking given by Sir Richard Gresham, on the part of the City, that these hospitals should be kept especially for the poor and indigent, and that the patients treated at them should be treated by properly qualified physicians, surgeons, and apothecaries.

"The latter of these two points we consider of the utmost practical importance. The popular impression is, that hospitals are places where those who are sick or injured have only to apply, in order to obtain the best medical advice and medicines, and where the most skilled physicians and surgeons render their personal assistance to all who apply. However true this may be as regards the in-patients, it is certainly not true with reference to the out-patient department of large hospitals, in which the number of qualified medical men is usually quite inadequate to do any but a small proportion of the work; the inference being that the remainder is done by unqualified students, or some other persons not appointed for the purpose.

"The system has thus become, to a certain extent, one of deception on the public, the sick being attracted to hospitals by the names of famous physicians and surgeons on their medical staffs, and being treated, when there, too often, we have reason to believe, by students in their second or third year of study, or at least by persons whose names are not before the public.

"The loss of time to poor working men and women, caused partly by this inadequacy of the medical staffs, and partly by the indiscriminate admission of all classes who like to apply at these departments, is something almost incredible—four, six, or even eight hours being not unfrequently lost in attendance and waiting for medicines, where two at the utmost ought to be sufficient.

"Your petitioners consider that it is neither creditable to the City of London nor to their own profession, that such blots as these should remain on the administration of our great medical charities, and therefore ask that you will either receive a deputation from them on the subject, or refer the matter to a committee, at which they may be heard.

"And your petitioners will ever pray.

(Signed) "T. HOLMES, Chairman of the Committee of the British Medical Association on Hospital Out-Patient Relief.

"M. A. EASON WILKINSON, M.D.

"A. P. STEWART, M.D., F.R.C.P.

"ALFRED MEADOWS, M.D.

"ROBERT J. LEE.

"JOSEPH ROGERS, M.D.

"J. FORD ANDERSON, M.D.

"H. NELSON HARDY."

Signed by Members of above Committee.

Resolved: That Mr. Holmes be requested to write to Sir Sydney Waterlow, asking if he would endorse the petition.

Resolved: That copies of the memorial be sent to each alderman, previous to the presentation of the petition to the Court.

Dr. Eason Wilkinson reported that as it took a long time to complete the report of the Subcommittee on Manchester Provident Dispensaries, in consequence of the number of institutions to be communicated with, it was not at present ready for presentation to this Committee. Circulars had been sent out to various institutions.

Mr. Hardy referred to Mr. Holmes's letter in the BRITISH MEDICAL JOURNAL, and suggested that it would be as well to circulate a copy of

it to each member of the Committee, and ask their opinion about adopting it as the future basis of the Committee.

At a meeting held on February 26th, 1878—Present: Mr. T. HOLMES (Chairman of Committee, in the Chair), Mr. Hardy, and Dr. Meadows. The minutes of the last meeting were read and found correct.

Read letter from Dr. Brierley, of which the following is a copy, viz.:

"Out-door Hospital Reform, Subcommittee of the British Medical Association, City Road, Manchester, Feb. 25th, 1878.

"My dear Sir,—At a meeting of the above Committee, held here on the 8th inst., letters were read from several medical officers of the Provident Dispensary Staff in this place, but no information of a definite character was forwarded. Ultimately, it was resolved that the only effectual way of getting the desired evidence was to employ a paid officer to visit the whole of the families at their own residence, and make inquiries as to the amount of weekly earnings, position, etc.

"The estimated cost of this work is £40 to £50; and I am instructed to ask you if the Association would feel inclined to lay out such a sum for the purpose.—Yours faithfully, "JAS. BRASSEY BRIERLEY."

The Chairman then read the letter that he proposed to send to Sir Sydney Waterlow.

Mr. Hardy read letter from Alderman Sir William Rose, declining to present the petition to the Court of Aldermen.

Resolved: That Alderman Sir William Rose's letter be entered on the minutes.

#### BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

THE sixth ordinary meeting of the session 1877-78 was held in the Queen's College, Birmingham, on March 14th, 1878. Present: Mr. SAMSON GANGE, President, in the chair, and thirty-nine members.

*New Member.*—Mr. F. S. Goulder of Dudley was elected a member of the Branch.

*Communications.*—The following communications were made:

1. Mr. LAWSON TAIT: Specimens of Thymol and Thymolised Lint.
2. Dr. MALINS: An Ovarian Cyst.
3. Mr. H. G. LOWE: Loose Cartilages from the Knee-joint.
4. Mr. H. M. MORGAN: Obstetric Tractors.
5. Mr. H. M. MORGAN: India-rubber Ring for Midwifery Forceps.
6. Mr. H. R. KER: A paper on Black Country Experience, Medical and Surgical.

#### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.

THE first meeting for the present year was held at the New Kentish Hotel, Tunbridge Wells, on Friday, March 29th: F. MANSEY, Esq., in the Chair. Twenty-two members and visitors were present.

*Next Meeting.*—It was decided that the next meeting be held at Lewes in the end of May; and that Mr. W. CROSSKEY be invited to take the chair.

*Communications.*—The following communications were made:

1. Dr. FAIRLIE CLARKE: Case of Diffused Melanotic Cancer originating in a Black Mole.
2. Dr. MILNER BARRY: Dr. Southey's Trocar and Cannula.
3. Dr. RANKING: Membranous Dysmenorrhoea.

*The Harvey Tercentenary Memorial.*—A letter from the Committee of the Harvey Tercentenary Memorial Fund was read and ordered to be referred to the Council of the South-Eastern Branch, recommending them to take it into their favourable consideration.

The *Dinner* took place at the New Kentish Hotel. Twenty-two sat down: Mr. F. MANSEY in the Chair. After explanations from Dr. C. HOLMAN, a resolution expressing confidence in the Committee of Council of the Association and approval of the course they had pursued was agreed to unanimously.

#### WEST SOMERSET BRANCH: SPRING MEETING.

THE spring meeting of this Branch was held at the Railway Hotel, Taunton, on Thursday, April 11th, at 5 P.M.: SAMUEL FARRANT, Esq., President, in the chair.

*Dinner.*—A good dinner was, as is usual at these meetings, the prelude to the business of the evening.

*Letters of Regret.*—Letters from ten members accounting for their absence, were laid before the meeting.

*Representatives of the Branch.*—Samuel Farrant, Esq., Taunton; F. J. C. PARSONS, Esq., Bridgwater; and Dr. Kelly, Honorary Secretary; were elected as representatives of the Branch in the Council for the year 1878-79.

*Question for Discussion.*—The question of which notice had been sent to each member a month previously, viz., "Is the use of water desirable in dressing wounds?" was put from the chair to each gentleman present. A written answer from Dr. Cordwell, who was not able to attend, was read by the secretary. The weight of opinion and argument, as expressed in the answers given, was to the effect that it is not desirable to use water for dressing fresh healthy wounds.

*Communications.*—The following communications were made:

1. Case of Transposition of the Thoracic and Abdominal Viscera, by G. W. RIGDEN, Esq. The patient attended, and submitted himself for examination.

2. Compound Dislocation of the Astragalus and Removal of the Bone, by SAMUEL FARRANT, Esq. The dislocation was caused by the patient falling from some height. He was admitted into the Taunton and Somerset Hospital with the bone hanging by some tendinous shreds under the outer ankle. There was no fracture of either tibia or fibula. The wound healed perfectly, and there was no perceptible deformity from the loss of the bone. The patient attended, and exhibited his foot.

*Autumnal Meeting.*—Mr. STEPHENS of Ilminster proposed that the autumnal meeting should be held at Ilminster. The question was postponed to the summer meeting.

*New Members.*—Two new members were proposed.

#### STAFFORDSHIRE BRANCH: ORDINARY MEETING.

THE second ordinary meeting of this session was held at the London and North Western Hotel, Stafford, on Thursday, February 28th, 1878; present, Dr. ARLIDGE, President, in the chair, and twenty-two members.

*New Members.*—The following members of the Association were duly elected members of the Branch: Dr. Beales (Congleton), Dr. Edgar Flinn (Briowhills), Mr. McAlldowie (North Staffordshire Infirmary).

*The Dental Practitioners' Bill.*—A memorial in opposition to the above was considered, and afterwards signed by all the members present; and it was resolved that the memorial be at once presented to the House of Commons.

*Communications.*—1. Dr. J. H. TYLECOTE read the notes of a recent case of Pneumonia followed by Phlegmonous Erysipelas of the Left Foot and Leg, and two months after convalescence by an Abscess of the Buttock and Cellulitis of the thigh.

2. Mr. R. GARNER read notes of a case of Parturition complicated with Prolapsus.

3. Mr. VINCENT JACKSON read a record of a case of Stretching of the Outer Digital Nerve on the flexor aspect of the left forefinger.

*Alteration of Rules.*—The meeting having been made special, Mr. FOLKER proposed alterations in Rules 4, 9, and 13. All were carried.

#### SOUTH WALES AND MONMOUTHSHIRE BRANCH: SPRING MEETING.

THE spring meeting was held at the Joint Counties' Lunatic Asylum, Carmarthen, on April 4th; Dr. A. DAVIES, Ex-President, in the chair, in the unavoidable absence through illness of the President, J. TALFOURD JONES, M.B. Eighteen members were present.

Dr. Hearder kindly provided luncheon for the members on their arrival.

*New Members.*—Fourteen new members of the Association, and sixteen of the Branch, were elected.

*Grants of Money.*—On the recommendation of the Council, it was resolved unanimously:

1. That £3 3s. a year be subscribed to the Medical Benevolent Fund.
2. That a contribution of £3 3s. be made in support of the case of "Apothecaries' Company v. Shepperd."

*Harvey Tercentenary Memorial Fund.*—It was resolved, on the motion of Mr. WATKIN, that a donation of two guineas be subscribed to this fund; and that the Secretary, in forwarding it, should express the strong opinion of this Branch that, whatever monument or statue be erected to Harvey's memory, should be placed in some part of the metropolis, and not in any provincial town, however identified with his early history, as a national homage to his claims as a great discoverer.

*Branch Subscriptions.*—It was resolved: "That defaulters of two years and upwards be informed that, in the event of non-payment of their subscriptions on or before the next annual meeting at Neath, their names will, however reluctantly, be struck off the list of members."

*Representatives on the General Council.*—The following were elected: J. G. Hall, Esq.; Dr. Sheen; Evan Jones, Esq.; H. N. Davies, Esq.; Dr. Hearder; J. H. Wathen, Esq.; Dr. Edwards; Pearson R. Cresswell, Esq.

*Communications.*—1. Mr. H. NAUNTON DAVIES (Cymer) showed a Spina Bifida Cyst which had been successfully removed by Ligature and Amputation.

2. Mr. H. N. DAVIES also showed a specimen of Addison's Disease of the Suprarenal Bodies, from a case in which there had been a greenish-brown colour of the abdomen and cheeks. Both suprarenal bodies were adherent to the surrounding parts. The left was almost entirely disorganised into a cheesy matter; the right was hard and fibrous.

3. Mr. DAVIES also showed a portion of Indurated Carbonaceous Lung from a Collier.

4. Mr. E. R. MORGAN (Morrison) read a case of Paralysis after the application of a Plaster to the Nape of the Neck by an Unqualified Person.

5. Mr. J. G. HALL (Swansea) read a case of Fibroid Tumour growing from the upper surface of the Uterus, removed by abdominal section: death.

6. Mr. J. H. WATHEN (Fishguard) read Hints on the Treatment of Neuralgia, mentioning more particularly the hypodermic injection of morphia and the use of tetrachloride of carbon.

7. Mr. WATHEN also showed an improved Splint for the Treatment of Fractures and Injuries of the Leg, made by Arnold and Son. It is light, inexpensive, and can be shut up into a small compass.

8. Dr. HEARDER (Carmarthen Asylum) read notes of some peculiar Abnormalities about the Heart in an Epileptic.

9. Dr. HEARDER also showed some cases of Hæmatoma Auris in Insane Patients, and the favourable results of treatment by blistering.

*The British Medical Journal.*—The following resolution, on the motion of Mr. E. R. MORGAN, was passed unanimously: "That this Branch begs to suggest to the Journal Committee that in future the JOURNAL be issued to the members with the pages cut, unless there are substantial financial reasons for not doing so."

*An Appeal* on behalf of the family of the late Mr. J. L. Thomas of St. Clears was made, and a letter on the subject was read from Mr. Dyke (Merthyr) by Dr. Hearder. It was resolved that the matter be postponed till the annual meeting.

*Visit to the Asylum.*—An interesting visit was then paid to the wards of the Joint Counties' Asylum, under the able guidance of Dr. Hearder, the Superintendent; and afterwards the members and visitors dined together at the Royal Ivy Bush Hotel, Carmarthen.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 23RD, 1878.

WILLIAM WOOD, M.D., Vice-President, in the Chair.

*Ophthalmoplegia Externa.*—Mr. JONATHAN HUTCHINSON showed two patients who had paralysis of the muscles of the eyeball, and consequent inability to move the eyes. He proposed for the condition the name of ophthalmoplegia externa.

ON TRANSVERSE CALCAREOUS FILM OF THE CORNEA. BY EDWARD NETTLESHIP, F.R.C.S.

THE disease, a somewhat rare one, had been described by various authors, but chiefly in its local relations. The chief objects of the paper were to draw attention to some points in the natural history of the disease which may throw light on its causation, and to confirm the statements of earlier writers, especially Dixon and Bowman, as to the good results of local treatment in suitable cases. A thin film of crystalline, chiefly calcareous, substance was formed beneath the anterior corneal epithelium; it could be chipped off in little flakes, leaving the underlying cornea clear. It was limited to the parts habitually uncovered by the lids, and when complete it formed a broad nearly transverse stripe terminating at each end a little within the lateral boundaries of the cornea. The symptoms as a rule were very slight, and there were generally no complications, even when the disease was of many years' standing; but sometimes chronic iritis and glaucoma came on. Occasionally, ulceration took place on the diseased patch. It seldom began in both eyes at the same time, but was almost invariably symmetrical in the end. The film was formed slowly, and might continue to increase for some years. The disease was one of middle and advanced life; and its subjects, almost without exception, were males. Occupation seemed to have no direct influence. The morbid ten-

dencies of the patients, so far as they were known, led the author to suggest that, in regard to causation, excess of uric acid in the blood furnished the most likely explanation from the constitutional side, though local peculiarities not yet understood were necessary as determining causes. Several new cases with naked eye and microscopic drawings were given. The paper was supplemented by abstracts of all the published cases (fifteen in number) known to the author; and in some of these (recorded some years ago by Dr. Fairlie Clarke) the present condition of the patients had been ascertained.

Mr. H. POWER had seen several of these cases, and had always considered them gouty. In one, there was whitish matter under the lids. Portions of the membrane on the eyeball could be picked off with the point of a knife, like the shell of an egg. This could be done with ease. Little irritation followed. He had also employed glasses with a small central hole in them, but patients did not like the restricted field of vision.—Mr. HUTCHINSON did not think the cases so closely connected with gout as Mr. Power believed. Probably there were many causes at work, mostly indications of senility. The condition reminded him of Dupuytren's contraction of the palmar fascia, where the exciting causes were numerous, but all probably neurotic. It was a question whether there was not some connection between that malady and the one now described.—Mr. NETTLESHIP was not aware that gout had been referred to in Messrs. Bowman and Dixon's cases. He had no note of the condition of the palmar fascia. He had, since the paper was written, seen another case in a woman who had only one eye affected. It was of long standing. She was not gouty, but had become hemiplegic.

THE TREATMENT OF SEVERE ARTERIAL HEMORRHAGE FROM PUNCTURED WOUNDS OF THE THROAT AND NECK, ESPECIALLY CONSIDERED WITH REGARD TO LIGATURE OF THE EXTERNAL CAROTID ARTERY.

BY WILLIAM HARRISON CRIFFS, F.R.C.S.

The paper discussed the treatment to be adopted in cases of severe arterial bleeding, that had resisted all simple means, and in which operative measures became necessary. The class of case included punctured wounds about the angle of the jaw and through the mouth, hæmorrhage from the tonsils, or from cancer of the tongue or mouth, secondary hæmorrhage after surgical operations, etc. The treatment usually adopted in these circumstances had been a ligature upon the common carotid. Upon analysis of a considerable number of cases, it was found that, after this method of treatment, rather more than half the patients died. The causes of these deaths were approximately as follows: rather more than 30 per cent. from brain-symptoms; the same proportion from recurrence of the bleeding; and the same from other causes. It thus appeared that one-third of the deaths were directly due to ligature of the carotid, and that in another third the operation had proved useless for arresting the bleeding. The brain-symptoms appeared to result from the already anæmic brain having a considerable portion of its blood-supply suddenly cut off. Hæmorrhage occurring from the original wound (after ligature of the common trunk) must either be due to the blood coming as a regurgitant stream brought down the internal carotid, or to blood being brought through the fine anastomoses of the terminal branches. Experiments and facts were narrated in the paper to show that in a certain number of instances the bleeding was due to a regurgitant stream through the internal carotid, or to the blood brought to the proximal end of the wounded vessel by the inferior thyroid. A table accompanying the paper showed how the bleeding vessel, wounded in the situation described, had most commonly proved to be the external carotid or one of its branches, a wound of the internal carotid being of rare occurrence. The cause of the high mortality following ligature of the common carotid artery having been discussed, ligature of the external carotid about half an inch from the bifurcation was recommended as likely to prove a safer and more efficient method of controlling the bleeding. The grave danger of cutting off the blood-supply to the brain was avoided by this operation, while at the same time the chance of recurrent hæmorrhage was diminished in proportion to the number of instances in which it occurred as a regurgitant stream. The objections raised to the operation were: 1. The fear of secondary hæmorrhage from the proximity of large branches; 2. That, should the wounded vessel prove to be the internal carotid, a ligature upon the external would be an useless operation. The first objection was answered by reference to cases narrated by M. Guyon, showing the rare occurrence of secondary hæmorrhage from the external carotid. The second was met by the comparatively few instances in which the wounded vessel had proved to be the internal carotid. Moreover, should the mistake occur, it was not beyond remedy, for a ligature might still be placed on the common trunk at its bifurcation; on the other hand, no remedy could be found for a patient

dying in a comatose condition, caused by obstructing the internal carotid on account of a wound of the external carotid or one of its branches.

Mr. HOLMES only remembered one case where the wound was through the mouth. A child was carrying a pointed stick of some kind when the injury was inflicted. He thought the internal carotid was wounded, and so tied the common carotid. The child did well. These are the cases where surgeons think it best to tie that vessel. If a tonsillar branch of the external carotid artery were wounded, then it would be a good plan to tie that vessel, but he could not think it was always so.—Mr. MORFANT BAKER spoke of a case he had seen where a man was injured by the stem of a tobacco-pipe entering the walls of the mouth near the tonsils. Much bleeding followed, and the man really died of this. He tied the common carotid. In this case, tying the external carotid would have been of no use. Still, he thought Mr. Cripps's plan seemed a good one.—Mr. CRIPPS had only collected seven or eight cases of juncture through the mouth. In only one of these was the internal carotid artery wounded. In most instances, the vessel wounded was the tonsillar branch of the facial.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 12TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Bilateral Paralysis of the Posterior Crico-Arytenoid Muscles.*—Dr. FELIX SEMON read a paper on this disease. He began with a few physiological remarks, explaining its pathogenesis. The size of the glottis seen in the living was larger than the same seen in the dead subject. This difference was due to the expanding force of the posterior crico-arytenoid muscles. In cases of bilateral paralysis of these muscles, the glottis was reduced at first to the size found after death, the so-called "cadaveric" position of the vocal cords; later on, however, the narrowing was still more developed, in consequence of the secondary "paralytic contraction" of the antagonists of the paralysed muscles. Finally, the glottis was reduced to a mere linear slit, the vocal cords nearly touching each other. The consequence of this grave change was dyspnoea in so characteristic a form that, even without the laryngoscope, one could diagnose with a great amount of probability bilateral paralysis of the posterior crico-arytenoids, if this dyspnoea were present. Its peculiarity consisted in the fact that it was exclusively an inspiratory one, while expiration was effected without difficulty, and the voice remained quite unimpaired. Dr. Semon remarked that the complete freedom of expiration which existed, even when the inspiratory dyspnoea had led to very grave changes in the circulation and other secondary symptoms, was most remarkable, and wanted some better explanation than could be given at the present time. He then proceeded to the communication of the case. The patient, an inspector of the Metropolitan District Railway, aged 32, had enjoyed good health until two years ago. Having been subject to several severe colds, he was one day attacked by violent cough, followed by slight dyspnoea. Although this symptom disappeared quickly at that time, it had from that date appeared more and more frequently. At the present time, the breathing was permanently somewhat impaired. Cough with consequent deep inspiration was sure to bring on a more or less severe attack of dyspnoea. Lately, some other symptoms had appeared. The patient was drowsy; he complained of weakness, itching, numbness, and fibrillar convulsions in both legs, especially in the left, and sometimes of slight incontinence of urine. He was then introduced; and Dr. Semon showed that there was slight ptosis of the left eyelid; that the left pupil was smaller than the right; the left nasolabial fold more distinctly visible than the right, and the left oral angle a little lower than the right. Further, the uncertainty in the patient's gait was shown. Dr. Semon then demonstrated the laryngeal symptoms: permanent slight inspiratory dyspnoea, which was much increased when the patient was told to cough, easy expiration, and unimpaired voice. He also described the laryngoscopic appearance of the glottis: the rima glottidis much smaller than normal; complete approximation of the vocal cords during phonation; if deep inspiration were intended, the cords separated only a very little from each other, and returned at once to their former close approximation. The act of separation was effected not by a continuous movement, but by several oscillations. This condition was illustrated by drawings; and, after the meeting, was shown laryngoscopically to members of the Society. This case was the sixth observed within the past two years by Dr. Semon in the Hospital for Diseases of the Throat and Chest, Golden Square. As the disease was a very rare one, he briefly communicated his experiences relating to the age and sex of the patients, the duration of the disease, the differential diagnosis, the etiology, prognosis, and treat-

ment. All the patients were men between thirty and sixty; and, with one exception, they had suffered between eight months and two years before they came to the hospital. The exception occurred in a case which proved without doubt that there existed a functional paralysis of the posterior crico-arytenoids, similar to the functional paralysis of the adductors of the vocal cords often seen in hysterical women. Dr. Semon then said that there was generally no serious difficulty in distinguishing between the disease under consideration and spasm of the glottis, but that it was in some cases quite impossible to make during life a differential diagnosis between paralysis of the posterior crico-arytenoids and ankylosis of both arytenoid cartilages. This was proved by examples. With regard to the etiology, he said that one of his six cases resulted from functional disorder, one from compression of both recurrent nerves by firm connective tissue (proved by the *post mortem* examination), two from catarrhal influences, and one from perichondritis (proved by the *post mortem* examination). The last case, shown to-night, was of special interest in this respect. He had looked upon the other nervous symptoms mentioned before as a very interesting, but merely accidental, coincidence with the paralysis, for the long time which had elapsed between the beginning of the latter and that of the other symptoms, as well as the integrity of the other organs supplied by the pneumogastric nerve, seemed to prove to him that there was no organic connection between the two groups of symptoms. But Dr. Hughlings Jackson, who had seen the case with him, thought that there was no doubt that the paralysis was due to central disorder, probably to a wasting process in the medulla oblongata. One case of this kind had of late been described by Penzolat. The prognosis seemed to be favourable in cases of functional paralysis; in all others, at least, very doubtful. With regard to the treatment, Dr. Semon thought that functional paralysis did not require other than constitutional treatment. Owing to the complete failure of all other remedies experienced here and abroad, in recent cases of purely neuropathic character, the direct application of electricity to the paralysed muscles might be tried, although all observers agreed that it did not prove itself as useful as in other paralyses. No percutaneous application should be instituted, inasmuch as the irritation of the healthy fibres of the vagus supplying the antagonists would lead simply to stronger contraction of those and still more marked narrowing of the glottis. In accordance with all other observers, Dr. Semon urgently recommended in all the more developed cases the early performance of tracheotomy. Even the small number of observations at present showed that, owing to the gradual poisoning of the blood by carbonic acid, the chances of recovery after the operation were the worse the longer it was postponed. If performed in time, it not only saved the patient's life, but also restored him to health with the only disagreeable modification that in all probability he had to wear his tube for ever. Dr. Semon concluded by returning thanks to Mr. Callender, Dr. Hughlings Jackson, Dr. Morell Mackenzie, and Dr. De Havilland Hall for their valuable assistance in making up his reports.

The PRESIDENT said that, having been permitted to read Dr. Semon's communication, he might say of it that it was one honestly worked out in the direction encouraged by the Clinical Society, showing how, by precise observation, facts of detail might be and should be carefully recorded. There were many points of interest in the paper; but he might perhaps select one of great importance, namely, the question as to the local or general nature of the affection. It was, of course, easiest to refer the truth to some one of the local causes named by the author; but it was at the same time evident that the general ataxic condition of the patient required attention. With reference to a central origin for the paralysis, it had been suggested that the affection, which, by the way, was bilateral, might be due to some change in the medulla, affecting the origin of the pneumogastrics; but, granting the origin of the nerves in the portion of the brain named, it seemed difficult so to differentiate as to justify the assumption that, whilst the nerves in their greater distribution retained their normal functions, a few of their fibres, supplied to the muscles affected, had lost all that which one recognised as nerve-force. This was but one point suggested for consideration, but, lying as it did at the root of the explanation of the cause of the malady, it seemed to him one of great interest for discussion.—Dr. DOUGLAS POWELL thought that one point of interest in Dr. Semon's case was the evidence it gave in favour of the view that, in some cases of mediastinal tumour, the dyspnoea arose from paralysis of the vocal cord rather than from spasm. Here was a case in which the dyspnoea was solely due to the paralysed cords being sucked together, by atmospheric pressure, during any strong inspiratory effort. He was rather surprised that, with such frequent paroxysms of dyspnoea, the lungs had not become congested and oedematous; and he could not but think that even a slight attack of catarrh might prove dangerous. He wished to know whether, in view of the very hazardous

present state of the patient, Dr. Semon did not contemplate the necessity of laryngotomy.—Dr. SEMON, in reply, said that he quite agreed with Dr. Powell that, theoretically, one would expect serious changes in the lungs in consequence of the gravely altered conditions of respiration. Practically, however, this did not appear to be the case. He had made two *post mortem* examinations in such cases; in one of them, it was true, chronic pneumonia was present, but this was without doubt due to primary pulmonary affection; in the other, there was only slight hyperæmia and uncommonly dark colour of the blood, the lungs being healthy in all other respects. In the case of the patient shown to-night, there was certainly no lung-disease. With regard to Dr. Powell's remarks on the treatment, Dr. Semon was very glad that they agreed so fully as to the necessity of tracheotomy being performed early in the case.

*Electrolytic Treatment of Epulis.*—Mr. NUNN read a paper on this subject, giving particulars of four cases, one of which had been under the care of Dr. McOscar of Argyll Street. A series of casts showed the progress made from time to time in the shrinking of the growth in that instance. Of the first case, that of a middle-aged lady, the following details were mentioned. 1. The number of sittings was large, about twenty. 2. The number of cells used was seldom more than six, often only three. 3. The tumour bled freely at first, on puncture with the electrodes. 4. The tendency to bleed diminished in a remarkable manner as the tumour decreased. 5. The pain caused by the electrolytic current was in proportion to the number of cells employed. 6. The pain was unbearable when the electrodes touched the periosteum of the jaw. 7. Pain ceased immediately on withdrawal of the needles. 8. As the tumour shrank, the expanded alveolus resumed its normal shape and size. 9. An injection of chloride of zinc into the tumour, at one of the sittings, produced such subsequent pain that the experiment of injection was not repeated. The patient was now wearing artificial teeth with comfort, and was free from all inconvenience. In the second case, casts were taken to show the appearance of the alveolar border after electrolytic treatment, compared with the result of removal by the ordinary operation. The patient had been operated on by the late Mr. De Morgan, in the Middlesex Hospital, for epulis of the lower jaw, and by Mr. Nunn for epulis of the upper jaw. In the latter instance, the patient was not incapacitated from attending to her duties even for a day, while the loss of normal tissue was considerably less. In Dr. McOscar's case, the diminution of the growth was followed by great improvement in the patient's general health, and by the disappearance of swelling and tenderness at the angle of the jaw and down the side of the neck. The fourth case was still under treatment. Mr. Nunn referred to a Clinical Lecture of Mr. Cæsar Hawkins, delivered at St. George's Hospital, for a description of the difficulties of the ordinary operation. As regarded the apparatus employed in the electrolytic treatment of tumours, "Leclanché" cells, with platinum electrodes, had been found most convenient, as gold itself was too soft, and steel electrodes were seldom sufficiently well gilded to escape oxidation at one pole. Mr. Nunn expressed his indebtedness to Dr. Julius Althaus for his first lesson in the electrolytic treatment of morbid growths.

Mr. MAUNDER said that the subject of Mr. Nunn's communication, electrolysis of tumours, was well worthy of consideration. Unfortunately, the process appeared to be both painful and very tedious; and he thought the choice of the method of operation, whether as above described or by the knife and bone forceps, must be left to the determination of the patient. His experience in the surgery of the jaws, somewhat extensive, had taught him that hemorrhage in operations for epulis need not be considered in the decision, supposing the tumour to be cut out, as it ought to be, and not cut into.—Mr. H. MARSH's experience of the treatment of nævi by electrolysis was disappointing; so that such method of treatment had now fallen out of use at the Children's Hospital.—Mr. PUGIN THORNTON had treated nasal polypi by electrolysis; but the method was extremely tedious.—Mr. GOLDING-BIRD had not tried electrolysis upon epulis, but on subcutaneous nævi he had been as unsuccessful as Mr. Marsh. Cutaneous nævi of small area he had destroyed, but thought that the mere laceration of the blood-vessels by the needles had very much to do with the subsequent disappearance of the growth. There were two ways of employing the electrolytic process: one in which "indifferent" electrodes, as platinum or gilt steel, were thrust into the tumour; another in which the positive electrode was of a metal, as zinc, that was itself altered by the electric current, and so a further electro-chemical change was introduced. In the former plan, the only electro-chemical action was that produced upon the salts in the tumour, bringing about an alteration in nutrition; in the latter, the chlorine from the decomposition of the chloride of sodium in the serum of the blood was attracted to the positive or zinc electrode, and chloride of zinc was formed. Thus was added to the electrolytic action proper that of a powerful caustic; and, used in this

way, it was scarcely, if at all, more painful than the simple passage of the electric current with "indifferent" electrodes. He recommended this method to Mr. Nunn as a more expeditious one for destroying epulis. He had employed it extensively, and with great success, in the destruction of scrofulous lymphatic glands.—Dr. ALTHAUS said he was surprised to hear that there had been so much disappointment experienced with regard to the effects of electrolysis in tumours. He had no personal experience concerning the electrolytic treatment of epulis, but in many other tumours the result had been most satisfactory, and not nearly so tedious as had been said. He thought that the mode of application must have had a good deal to do with the different results obtained, as the different action of the positive and negative pole was not yet generally understood. In nævus more particularly, he had had very good results where other surgical operations, such as the ligature, nitric acid, and vaccination, had failed. In naso-pharyngeal polypus, several continental surgeons, such as Professor von Bruns of Tübingen, had been very successful. In bronchocele, the ablest and boldest surgeons sometimes refused to operate; and he instanced a case in which the late Sir William Fergusson had sent a patient, who was in imminent danger of suffocation from pressure of the tumour on the pneumogastric nerve, home to die, without attempting any operation; this patient was subjected to electrolysis when nearly moribund; he was out of danger within a few days, and in a few months the tumour was entirely gone, and had not at present returned. In the presence of such results, to which a good many others could be added, he felt sure that electrolysis would always retain a footing in operative surgery.—Mr. GOLDING-BIRD appreciated the advantage of both poles being inserted into the growth; but thought that the caustic effect of the chloride of zinc produced at the positive pole should not be neglected.—Mr. H. MARSH had introduced both needles into the nævi treated by him.—Mr. NUNN, in reply, said that he had had large experience in the treatment of nævi by electrolysis, and had found great benefit result. The injection of chloride of zinc itself produced great pain in a case of epulis. The disease in this case could not have been eradicated with the knife without much trouble and possible loss of blood.

*Psoriasis treated by Chrysophanic Acid.*—The PRESIDENT said that Mr. Hutchinson had sent to the meeting a patient for the inspection of the members. He was the subject of psoriasis. The disease on one half of the body had been treated with chrysophanic acid ointment, and was cured; the other half had been treated with tar ointment, and that portion of the eruption still persisted.

*Hammer-Toes and Plantar Bunion.*—Mr. NUNN read a paper on these subjects. The first case reported was that of a stoutly built man, aged 39, who was admitted into the Middlesex Hospital with a suppurating bursa over the head of the metatarsal bones of the third and fourth toes. Accompanying this condition was a retraction of the phalanges on to the dorsum of the foot (extreme extension of the proximal, with flexion of the distal phalanges). There had been, some six years previously, a severe contusion of the foot, which had, however, disabled the patient only for one week. It was suggested that the retraction of the phalanges had existed prior to the receipt of the injury, although the suppurating of the bursa might have been directly caused by it. A cast of the foot was exhibited to show that, in persons who had the phalanges retracted in the manner described, the rolling action of the foot in walking, spoken of by the physiologists, must come to an untimely end, ceasing at the head of the metatarsal bones, instead of continuing, as it ought normally, to the tips of the toes. Thus undue pressure and friction fell on the heads of the metatarsal bones. The second case was that of a lady, who, after a severe gastro-enteric attack in 1872, became the subject of very marked lordosis in 1873, the spine having curved forwards to such a degree that the patient's height was lessened by four inches. She was seen by Mr. Nunn in 1874 on account of the condition of her feet. The whole of the right inferior extremity was found imperfectly nourished, and the four outer toes had become retracted on to the dorsum of the foot. Great inconvenience was experienced by the patient from the contact of the flexed toe-joint against the upper leather of her shoe. Mechanical support was provided for the spine; and shampooing, baths, and faradisation had been diligently persevered in with satisfactory result. Instead of being quite crippled, the patient could now take fairly long walks; but there remained, nevertheless, to some extent, the retraction of the toes. The question was: Of what nature was the retraction of the toes in such cases? Reference was made to the position of the fingers in cases where the interossei had been paralysed by the section of the ulnar nerve near the wrist, and to the views of M. Duchenne as to the function of the interossei muscles. The author expressed his opinion that, at least one factor in the deformity under consideration was a disturbance in the innervation, or of the nutrition of the interossei of the foot; and that the source of such mischief was frequently spinal—either from interfer-

ence with the function of the spinal cord by curvature of the vertebral column itself, or from some morbid condition of the cord, or of the nerves. The author submitted that the existence of the retraction of the phalanges, *i.e.*, the condition known as hammer-toes constituted a symptom which should direct the attention of the surgeon to the spine. The same might be said of valgus, or flat foot. Dr. Little, in his admirable contribution on Orthopaedic Surgery in the third volume of Holmes's *System of Surgery*, first edition, wrote at page 610: "A slight degree of flat foot is common in girls, especially of the upper and middle classes." It was precisely in the sex and in the classes specified by Dr. Little that spinal curvature was common; it was, therefore, suggested that the flat foot was the result of spinal disorder, and not simply a local weakness. The author indicated as examples of the faulty nutrition and innervation of single muscles, strabismus and writers' cramp; and he stated that faulty nutrition of single muscles of the leg very frequently took place, and that ordinary bunions of the great toe was due more to an atrophic state of the extensor longus pollicis than to any dislocating action exerted by a badly made shoe. As a directly practical suggestion, an inspection of the shoes of the patient should be made; and, in the event of it being found that the sole was unduly worn across the middle of the foot, the condition of the spine should be inquired into. The paper concluded by saying that, if the spinal curve were not the origin of the deformity of the limb, it would, if neglected, certainly exaggerate the mischief, and would give rise to symptoms that would be unintelligible; and that, consequently, treatment would fail from the want of a rational basis.

The PRESIDENT said that, as regarded the atrophy of muscles in talipes, however much one might operate and use mechanical appliances, the old position of parts was subsequently very apt to be resumed.—Mr. MAUNDER remarked that Mr. Nunn's paper was highly suggestive, but somewhat alarming; and he trusted that, in a very large majority of cases of hammer-toe, Mr. Nunn's pathology would prove to be incorrect, especially as he (Mr. Maunder) had operated upon four contracted toes in the persons of three relatives with the happiest results, dividing the flexor tendons. These children's aptitude for play was remarkable. If Mr. Nunn meant to imply, by speaking of the toes as extended, that the extensor tendons should be divided to remedy the deformity, Mr. Maunder was sure that such an operation would be a failure. The explanation of plantar bunion offered was certainly reasonable.—Mr. W. H. BENNETT thought one of the most interesting points in the paper was that concerning the condition of the nervous system, and of sensation in the affected limb. In some cases of suppurating bursæ, the sensation in the leg was nearly lost. In one instance, after amputation at the ankle, the patient subsequently returned with considerable anesthesia in the limb. But there was in that case no idea of disease of the spinal cord.—The PRESIDENT suggested that cases of "perforating ulcer of the foot", described by French authors, seemed to be somewhat similar in their conditions to these cases of suppurating bunion of Mr. Nunn.—Mr. G. BROWN had had a case in which bunions on each foot had suppurated and led to ulceration and necrosis. That patient had had syphilis, and eczema of each leg.—Mr. D. ROTH had treated such cases of "hammer-toes" with stockings with toes, like the fingers of gloves.—Mr. NUNN, in reply, said that he thought the "perforating ulcer of the foot" of French authors was more of the nature of elephantiasis. Tenotomy would probably be of much use in the case he had brought forward. The position of the toes was due to paralysis of the interossei, which were extensor muscles of the toes; therefore, the proper course of treatment would be to divide the flexor tendons. Did not that condition of hammer-toes which began at puberty indicate something amiss with the nervous system, either in the cord or the nerves?

#### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 6TH, 1878.

CHARLES WEST, M.D., F.R.C.P., President, in the Chair.

*New Form of Metrotome.*—Dr. GALABIN showed a modified form of Dr. Peaslee's instrument. The principle was the same as that applied in Civiale's urethrotome, and in that of Sir Henry Thompson. It was especially applicable for incision in cases of stenosis of the internal os, although it might be used for the external os. The advantage was that it divided both sides equally, to an exact and very moderate extent; while Simpson's or other similar metrotomes were apt either to cut too deeply, or, if the operator were timid, not deeply enough. It could also be introduced through a very small canal; while the single- or double-bladed metrotomes were usually made larger than the ordinary sound, and could not be passed in the cases which most required incision. In the modified instrument, the tube was made round instead of

flat, which much facilitated its introduction. A spring was also introduced within the instrument, which prevented the blade from sliding forward prematurely, and returned it after use.—Dr. AVELING had for many years used an instrument very similar to that shown by Dr. Galabin. As a rule, he preferred metrotomes which cut only in one direction.

*Fibro-Cystic Disease of Uterus.*—The report of Dr. GALABIN and Dr. HERMAN on the tumour shown by Dr. THOMAS CHAMBERS at the last meeting of the Society was read, together with Dr. Chambers's account of the subsequent history of the case and of the *post mortem* examination. Sections of the tumour under the microscope were also exhibited by Dr. Galabin. These showed its structure to be that of a fibro-myoma, having very numerous and wide interspaces between the bundles of fibres. The subsequent history of the case, as given by Dr. Chambers, told that the patient died twenty-six hours after the operation. At the necropsy, the bladder was found to be very much elongated, and appeared to have been drawn upwards, as if by the ascent of the tumour, so as to form a cone-shaped cavity, the cone being involved with the tumour so intimately as to escape recognition during the operation. The result was the ensnaring of a small piece of the cone or fundus in the ligature which embraced the whole stump. Although the bladder was not inflamed, it was but fair to suppose that the injury it sustained contributed greatly to the result.

*Tubes for Injecting the Uterus after Parturition.*—Dr. HAYES showed a new form of tube which he had devised for the injection of the uterus after labour or abortion with a solution of Condy's fluid, or other disinfectant, and also for the injection of hot water. The advantages of this tube were its non-flexibility, its increased length, enabling it to reach the fundus easily, and the number of perforations in its extremity, so that the fluid was discharged into the uterus in the form of a spray, which ensured the whole of the uterine cavity becoming bathed by the fluid.—Dr. ROGERS had a precisely similar tube made for him twenty years ago. It was constructed of the same metal, and was perforated in the same way.—Dr. CLEVELAND had never heard of the short tubes condemned by Dr. Hayes being used for injecting the uterus. They were only intended for washing out the vagina.—Dr. MURRAY thought that the tube for intra-uterine injection should have large apertures in preference to small ones, which were very liable to become clogged up. He had used for many years a vulcanite tube of the same length as that shown by Dr. Hayes. In accordance with the views he had expressed, it had large apertures.—Dr. FANCOURT BARNES exhibited some vulcanite tubes which had been devised by Dr. Robert Barnes for injection of the uterus with solution of perchloride of iron after abortion. They contained pieces of sponge soaked with the solution, which was made to ooze slowly out through eyelet-holes at the end of the tube by means of a piston. The alleged danger of forcing the fluid through the Fallopian tubes into the peritoneal cavity was thereby obviated.

*Unicorned Uterus.*—Dr. HERMAN exhibited a specimen of an unicorned uterus. The uterus lay close to the right pelvic wall. The right Fallopian tube and ligaments were short, but otherwise normal. The left ovary was high up on the left side near the internal abdominal ring. The left canal of Nuck was very large, and a thick fibrous band proceeded from the ovary down this canal. The end of this band presented an enlargement, which was more vascular than the rest. A thin but firm and strong fibrous cord, between two and three inches in length, united the ovary to the upper part of the rectum. On the surface of the pelvic peritoneum, a flat band of slightly diverging fibres could be seen running from the cervix uteri in the direction of the left ovary. Both ovaries showed signs of having discharged ova. The patient was unmarried, and aged forty-nine. It was stated by her sister that she had ceased to menstruate for three years, that the flow had always been scanty, and that she never complained of pain. She died from capillary bronchitis.

*On Traction by the Lower Jaw in Head-last Cases.*—Dr. MATTHEWS DUNCAN contributed a paper on the subject. He commenced by saying that by the traction referred to two objects were professed to be gained—flexion of the head and extraction. Attempts to secure these objects by the fingers applied to the fossæ caninæ were in vain, because the force in a right direction available by such procedure was of too small amount. Besides traction of the lower jaw, there were two other sources of power: first, pulling by the feet or otherwise through the spine; this was the paramount force: second, expression, which, by mere strength of the accoucheur's arm, might be estimated as from 30 to 40 lbs., or, using the weight of the accoucheur's body, might reach 100 lbs. The dangers attending spinal pulling and expression were very considerable. Those of the latter method were as yet but little known. Danger in head-last cases, where the base of the skull was in the brim of the pelvis, was not from compression of the cord,

but from asphyxia and from inhalation of solid and fluid matters into the lungs. Speedy delivery was often desirable, and lower jaw traction deserved consideration when there was obstruction requiring the use of force, and when the other forces were not sufficient. Injuries resulted in two of Dr. Duncan's four experiments with lower jaw traction; separation of the two halves of the bone in one case in which 58 lbs. were suspended on it, and laceration of the inside of the mouth with distortion in another. The force applied through the lower jaw, acting as it did chiefly through the maxillary joints, was favourably applied for producing extraction, but not for producing flexion, because of the nearness of the joint to the centre of the head's motion, the bitemporal diameter (in a contracted brim). The whole force so applicable might be more than 58 lbs., and might certainly all be used in cases of dead children, or children certainly doomed to death, or in cases where the head was left *in utero*. Further experience was required to show how much could be safely used in a living foetus. Lower jaw traction did not produce considerable flexion of the head. Flexional efforts were seldom required. The paramount dragging by the spine, as it acted in a case of contracted brim behind the centre of the head's motion, annulled or undid any slight flexion produced by the lower jaw traction. But spinal pulling could easily be made to produce flexion after the head's passage of the brim by giving it a proper direction; and at this time flexion was essential.—The PRESIDENT said that years ago he used to practise and to teach the drawing down of the head, by applying the fingers of one hand to the canine fossæ and pressing up the occiput with the other hand. But it was now learnt from Dr. Duncan that it was not possible to achieve much by this method, nor, indeed, did it appear from his paper that much more could be done by traction on the lower jaw.—Dr. FANCOURT BARNES stated, with regard to the application of the forceps to the aftercoming head, that he had practised this operation on the phantom repeatedly, and had found it remarkably easy. He had no experience of the operation on the living subject; but he thought that it had many advantages over traction on the body of the child, for there was no danger of ricking the neck or injuriously stretching the spinal cord.—The PRESIDENT said that it had always appeared to him one of the great disadvantages of the use of the phantom, that operations upon it seemed uncommonly easy, and he had always hesitated to draw conclusions from these operations to those on living women.—Dr. MATTHEWS DUNCAN said that he had particularly pointed out in his paper that the method of Smellie—that of traction with the fingers in the fossæ canine and simultaneous pressure upwards on the occiput—was an efficient and valuable method of delivery in head-last cases.—Dr. PLAYFAIR said that of late years, since becoming familiar with the writings of Goodell on the subject, he had been much impressed with the great advantage of the expression of the head from above in these cases. It seemed to him that it was of primary importance not to depend on one method alone; and the great advantage of expression was, that it could be performed in union with traction.—Dr. CLEVELAND said that it was pleasing to learn that one might justifiably use such a large amount of force as mentioned by Dr. Duncan without doing any maternal damage. There still, however, remained one want, and that was, a means of determining what muscular force one was putting forth. How, he would ask, was the operator to know that he was using a force not exceeding fifty pounds?—Dr. ROPER said that the conditions present in different cases of head-last delivery varied very much. There was a great difference between the cases in which the head was delayed above the brim and those in which it was only delayed in the cavity of the pelvis. He believed that where podalic version had been effected as an alternative to craniotomy, the life of the child was often lost from the head being delayed at the brim of the pelvis. If the head were fixed above the brim, there was not much scope for manipulation, as it was hardly possible to reach the jaw and the occiput, and we had therefore to rely on traction by the spine in the axis of the brim. It was the later movement of the head through the pelvis which required its rotation on its transverse axis. This distinction had hardly been pointed out in Dr. Duncan's paper.—Dr. BRAXTON HICKS felt that there was considerable difficulty in discussing Dr. Duncan's paper, for the author had not attempted to treat the whole question of the delivery of the aftercoming head. Had he done so, he would probably have advocated a combination of traction on the chin and neck and pushing up the occiput, together with pressure from above, a plan which he had adopted and taught many years. But the point dealt with by Dr. Duncan was quite different from this general question, and consisted in the determination of how much force might be safely used in a particular direction.—Dr. WYNN WILLIAMS thought it well to point out that a living muscle, as regarded its resistance to tension, was under very different conditions from a dead muscle. He did not believe that a living child could safely bear the same force that could be applied with impunity to a

dead child. The active resistance of a living muscle made it much more liable to injury than a dead muscle; and a drunken man, in falling from his horse, almost invariably escaped injury, the reason being that his muscles were paralysed. He believed that much injury was often done by undue traction being made to deliver the aftercoming head.—Dr. CLEMENT GUDSON said that he had been much struck during Dr. Duncan's experiments with the small amount of force necessary to deliver the aftercoming head of an unusually large child on a phantom pelvis, with a conjugate diameter of three inches; and the question occurred to him, whether the soft parts did not interfere with delivery very much more materially than was generally imagined. He could not agree with Dr. Duncan in regarding with disfavour the application of forceps in head-last deliveries. He had himself, in one case, failed to deliver by Smellie's method; but, on applying the forceps, he had succeeded in at once extracting the head without any difficulty whatever.—After remarks from Mr. POOLE of Sidcup and Mr. MASON, the PRESIDENT pointed out that it was much easier to apply the forceps to the aftercoming head when the patient was delivered in what he might call the continental position, where she lay on her back. Here it was possible to secure ample space for the use of the forceps by drawing the body of the child well forward towards the abdomen of the mother.—Dr. MURRAY agreed with the President as to position making some difference; but he had, nevertheless, applied the forceps in two cases with complete success, though the patient remained in the ordinary position; and he considered that the use of the forceps was indicated sooner rather than later in the delivery of the aftercoming head when difficulty arose.—Dr. JOHN WILLIAMS had several times applied the forceps to the aftercoming head with the greatest facility. In the last case of this kind which he had seen, he had found it impossible to deliver by any other means.—Mr. COCKELL urged the importance of sweeping the body of the child round towards the abdomen before applying the forceps.

*A Case of Protracted Labour in which the Use of the Forceps was typically indicated.*—This paper was communicated by Dr. GEORGE ROPER. The case referred to in it occurred in October last, in a woman aged 40, who had had thirteen previous labours at full term, all of them severe. On being called to the case by a midwife, Dr. Roper found that delivery had taken place naturally except for the use of ergot, which had been given seventeen hours after the rupture of the membranes, the os being fully dilated. The drug was speedily followed by very severe and frequent pains, and delivery ensued in two and a half hours. The child, a male, weighing 9½ lbs., was still-born, and its appearance indicated that it had very recently died in its birth. The head was of very large size, and the ossification of the cranial bones was so complete that the fontanelles and sutures were nearly obliterated. For the purpose of contrasting this head with one of normal size, casts had been prepared, a comparison of which showed that the measurements of the former exceeded those of the latter in all the usual diameters by half an inch to three-quarters of an inch. Another interesting point in the shape of this head was, that the vault of the cranium was twisted on the base, so that the measurement from the left mastoid process of the temporal bone to the postero-superior angle of the right parietal was much greater than a corresponding line drawn between the same points on the opposite sides of the head. This lateral obliquity was probably to be explained by the severe pressure the left side of the vertex had to sustain against the ramus of the left ischium and pubes in the rotation of the head; the corresponding area of the right side of the vertex being exposed to no obstacle, but having the expanse of the pubic arch before it became elongated. In his comment on this case, Dr. Roper observed that he felt strongly that whenever it was determined to use forceps, the operator should be able plainly to state the indication pointing to the necessity of its use. In the present case, there were, apart from the death of the child, many indications of necessity: (1) Accidental discharge of liquor amnii at the very beginning of labour; (2) A woman aged 40, whose many previous hard labours had culminated the uterine force; (3) Great fatness, especially of the abdominal walls, and a weakened state of the abdominal muscles; (4) A large and hardly ossified head to be felt during labour; (5) Three hours of slow progression in the second stage of labour in a woman who had had twelve living children. Dr. Roper thought it could be scarcely doubted that, if forceps had been used an hour before the ergot had been given, the mother would have been delivered with much less suffering and of a living child.—After some remarks from Dr. HEYWOOD SMITH, Dr. WILKINS called the attention of the Fellows to the cast of the normal child, as well illustrating what he might call the natural asymmetry of the fetal head. The cast before them was very well adapted for this purpose, as, the child being delivered by the feet, the head had not undergone much compression during delivery. The two halves of the head might be equal in bulk,

though he doubted whether this were so; but, in sixty per cent. of the cases, which he had examined, the right half of the head was in a plane a little in advance of the left half. This asymmetry affected not only the cranial bones proper, but also the arch of the palate. His own observations had convinced him that it was independent of any compression to which the head might have been exposed during delivery, for it was seen in children delivered by Cæsarean section. He thought the fact was important, as it might have some influence on the mode of presentation of the head during delivery.

The meeting then adjourned.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, MARCH 2ND, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Enteritis Fatal on Eleventh Day.*—Dr. J. W. MOORE showed the intestines of a man aged 21, single, whose illness dated from a surfeit on February 16th and 17th, followed by injudicious dosing with senna and castor-oil without medical advice. Severe pain in the lower part of the abdomen, and shivering, with nausea, vomiting, and diarrhoea, were the earlier symptoms. He came into hospital on the fifth day, when his evening temperature was 103 deg., and there were a few *tâches blanches* on the chest. The abdomen was tense, full, and tender on pressure. Violent pain, with bilious vomiting, ushered in obstruction of the bowels, and he sank into a state of profound collapse. After death, only localised peritonitis was found. The colon and last three feet or so of the ileum were quite collapsed and intensely hyperæmic. Above the commencement of the collapsed condition of the intestine, the ileum was ballooned to an extreme degree, and large quantities of feces were present in the ileum, jejunum, duodenum, and even the stomach. No strangulation or invagination of the gut was discovered. The condition seemed to be one of paralysis from inflammation. Peyer's patches were everywhere perfectly healthy. A perforation had occurred in the distended portion of the upper ileum, through a frayed portion of the mucous membrane, too late, however, to induce a general peritonitis.

*Report.*—Dr. R. J. HARVEY brought up a report on a specimen of "black quarter" in a calf, described by Dr. Lyons at the meeting of December 15th, 1877.

#### MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.

WEDNESDAY, FEBRUARY 6TH, 1878.

THOMAS FITZPATRICK, M.D., in the Chair.

*The Late Drs. Stokes and Churchill.*—Dr. H. KENNEDY moved, and Dr. MAC SWINEY seconded, the following resolution, which was unanimously adopted, "That at this, the first meeting of the Medical Society of the College of Physicians held since the lamented deaths of Dr. Stokes (a Vice-President of the Society) and of Dr. Churchill, the Society desire to express their sense of the irreparable loss occasioned by the removal of two such distinguished members of the profession—one the leader of Irish medicine, and the other amongst the foremost cultivators of obstetric science; and that the Honorary Secretary be requested to convey a message of condolence to the relatives of the deceased."

*Case of Obstructed Circulation.*—Dr. J. P. DOYLE brought forward the case of a woman aged 32, who was attacked five weeks after her confinement (of twins) by a feeling of oppression about the heart, and palpitation. Two days later, she appeared to be dying of asphyxia. Dr. Doyle described her state at this time as follows. She was sitting up in bed, gasping for breath, and spoke in a sighing, interrupted manner. The intellect was clear, the complexion livid, and the expression one of anxiety and fear; the surface of the body and extremities felt cold and clammy, and the forehead was covered with large drops of perspiration. Temperature in axilla, 97 deg.; the bowels, which were naturally regular, were costive; tongue clean; she had a slight, dry cough, with little expectoration. Pulse, scarcely perceptible, 140. The circumference of the thorax was thirty-one inches; on inspection, it presented a narrowed appearance transversely, which was due to an increased curvature of the ribs behind, and a slight prominence of the upper fourth of sternum. Resonance was slightly diminished on percussion anteriorly over both lungs. What appeared like a dry crackling was heard on auscultation anteriorly over both lungs, but was most intense over the right; otherwise, the air entered freely. The percussion-note posteriorly was normal, and the vesicular murmur clear and weak. The area of cardiac dulness was increased towards the right side, and

made the organ seem as if placed vertically. The cardiac beat was not visible, and the impulse was indistinctly felt towards the mesial line. The first cardiac sound was very weak, and the second was not audible. The jugular veins were distended, but did not appear to pulsate. The patient recovered after two similar paroxysms at periodic intervals of about ten days. Dr. Doyle, amongst other suggestions as to the probable cause of these peculiar and apparently periodic attacks, asked whether spasm of the arterioles of the pulmonary artery might not account for the symptoms. A thrombus of the right side of the heart or an embolus of the pulmonary artery would also be a plausible explanation of the paroxysms.—The CHAIRMAN thought that a recent paper by Dr. Fothergill on Simulated Diseases of the Heart (*Edinburgh Medical Journal*) bore on Dr. Doyle's case.—Dr. MAC SWINEY looked upon the affection as cardiac asthma.—Dr. HENRY KENNEDY would describe the patient as a nervous female of asthmatic tendency, with temporary dilatation of the right heart.—Dr. FINNY said he thought the whole *rationale* of the case pointed to a thrombus of the right auricle, followed by embolism of branches of the pulmonary artery. The puerperal state from which the patient was emerging, her weak and anæmic condition, and the occurrence of a "bad turn" on hearing some exciting intelligence—all supported this embolic theory.—Dr. DOYLE, in reply, said he must concede to Dr. Finny the merit of having given a very clear explanation of the phenomena observed.

The Society then adjourned.

## CORRESPONDENCE.

### CONSULTANTS' PROFESSIONAL ETIQUETTE.

SIR,—As an illustration of the causes of the misunderstanding that has arisen between consultants and general practitioners, I will relate two cases that have lately occurred in my practice, and, at the same time, make a few remarks on the method by which such misunderstandings could be avoided.

A gentleman who has been attended by me for some time, and who has cancer of the rectum, went without my knowledge to consult a celebrated physician, at the same time telling him that he was under my care, and that I had informed him he had a tumour of a serious nature in the rectum. The physician prescribed a simple mixture of salts, etc., without making any rectal examination (although my patient was passing blood *per rectum*, etc.), and did not in any way communicate with me, so that I only found it out by accident on my next visit.

Again, a lady that I have attended for years, and who is still under my care, went at the solicitation of her friends to consult an eminent oculist for an affection for which I was then treating her. This gentleman, although my patient told him she was under my care, did not communicate with me, but simply wrote a prescription for a different tonic from what she was then taking, and I only heard of it by my patient handing me the prescription.

I do not at any time object to a consultation, but I do complain greatly that consulting men in London should see patients, who are under the care of their regular medical attendant, and who tell them such is the case at the time of their visit, without in any way communicating with the medical man on the subject. Instead of doing so, they write a prescription, often a simple change of tonic or other medicine, and thereby give rise to a feeling of dissatisfaction with the former treatment, not unfrequently resulting in the loss of a good patient. Happily, this is not always the plan adopted; and I would recommend, as in accordance with true medical etiquette, that in all such cases the patient should be told, that no opinion would be given without first communicating with his medical man. This, of course, is always supposing the patient is to return to the care of the former attendant. I shall be glad to hear your opinion of this matter, and whether there are other members who have the same complaint to make.—Yours faithfully,

M.B. LOND. AND F.R.C.S.

### THE ANTISEPTIC TREATMENT.

SIR,—The antiseptic treatment is so generally adopted and is spreading so widely, that we think it almost time to ask, through the medium of your most influential JOURNAL, if we may not possibly be encouraging a great delusion. Whilst we are neutralising the septic action of the atmosphere on the wound, are we not losing sight that the patient is breathing this atmosphere, which the antiseptic treatment proclaims to be poisonous? Surely this "antiseptic treatment" is a retrograde movement, taking us back to the ages of specifics and to the dread of fresh air. Can carbolic acid possibly be a substitute for

oxygen, Nature's disinfectant and purifier? Would it not be more rational to apply an efficient antiseptic treatment to the hospitals and wards in which the septic atmosphere is generated, so that the general health of the patient may be supported and the wound healed under the influence of pure fresh air and light simple dressings? Apologising for occupying your space, I am, sir, yours faithfully,

CHARLES SHRIMPTON, M.D.

Whitehall, S.W., April 15th, 1878.

### TEACHING OF PHYSIOLOGY IN DUBLIN.

SIR,—I am quite unable to perceive that Professor Mapother has supplied any fact by his letter of the 8th instant which was not before you in mine of the 30th ult. Surely he cannot mean to imply that no course of operative surgery has been accepted since 1874. If this be his meaning, he is certainly greatly mistaken.

I shall not trouble you with any criticisms on his letter; it speaks for itself. He has shown what his idea of practical teaching is: and, as his influence on the Council of the College is very great, the difficulties I have to contend with will be all the more readily understood. I may, perhaps, be allowed to assure him that the introduction of a course of laboratory instruction will not do away with the illustration of lectures by specimens and experiments, any more in physiology than in chemistry.

As to Professor Mapother's last paragraph, I have only to say I do not wish to occupy your space or to trouble your readers with personalities. My object was to call attention to what I consider a great injustice to Irish students, and to such of their teachers as are anxious to keep pace with the ideas which everywhere else prevail.

In conclusion, I beg to thank you for the very material aid your remarks in the JOURNAL of the 6th instant have given my cause, by showing that what I am seeking is neither monstrous nor new, but only what is generally regarded as essential.—I am, sir, faithfully yours,

REUBEN J. HARVEY.

7, Upper Merrion Street, Dublin, April 15th, 1878.

## PUBLIC HEALTH

AND

### POOR-LAW MEDICAL SERVICES.

#### POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

THE annual general meeting of this Association will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, on Tuesday, May 7th, at 3 P.M., when several matters of interest to the members of the Poor-law Medical Service will be discussed. After the meeting, the members will dine together; tickets, 7s. 6d. each, exclusive of wine. As this association has conferred great benefits by its public work on the members of the Poor-law Medical Service, the Council trusts—we hope with good prospect of success—that a large number of the members will attend. Gentlemen who intend to dine are requested to send their names as early as possible to J. Wickham Barnes, Esq., Honorary Secretary, 3, Bolt Court, Fleet Street.

#### THE BROMYARD BOARD OF GUARDIANS AND THE MEDICAL OFFICERSHIP OF THE CRADLEY DISTRICT.

IN the JOURNAL of February 16th, we alluded to an appointment which was made in the Bromyard Union in violation of the orders and regulations of the Local Government Board, and a hope was expressed at the time that the department would withhold its sanction to it. Not only was this done, but the facts of the case were laid before the Local Government Board by Dr. Lush, M.P. for Salisbury, in a letter which he addressed to Mr. Slater-Booth on the subject. The action thus taken, it will be seen by the letter subjoined, has been attended with the best results.

"Local Government Board, Whitehall, S.W., April 5th, 1878.

"Sir,—I am directed by the Local Government Board to acknowledge the receipt of your letters of the 16th and 18th ultimo, respecting the proposed appointment of Mr. G. E. F. Etheridge as medical officer for the Cradley District of the Bromyard Union.

"In reply, I am directed to state that the board are unable to sanction the appointment of Mr. Etheridge as medical officer for the above-mentioned district, inasmuch as he already holds the offices of medical officer for the second district and the workhouse of the Bromyard Union, and also of medical officer for the Knightswick District of the

Martley Union. The board considers that the appointment as district medical officer of a medical practitioner whose residence is situated at a distance from the district when there are other duly qualified medical men willing to accept the office, and resident nearer to the district, is contrary to the principle of the general regulations relating to the office of medical officer.—I am, Sir, your obedient servant,

"HUGH OWEN, Junior Assistant Secretary.

"To H. N. Knott, Esq., Clerk to the Guardians of the Bromyard Union."

### PUBLIC HEALTH ADMINISTRATION.

A VERY good illustration of the average mode of administering sanitary laws by small local bodies is afforded by the recent proceedings of the Denbigh Town Council. The medical officer of health had resigned, and the mayor observed that he was "a very good man; a very good man indeed; his only fault was, that he reported too much and went into details". To mend this defect, it was arranged to appoint a successor whose salary should be cut down to £25 a year, on the understanding that he would not report too much, and that his chief duty would be to furnish extracts from the birth and death returns. It was explained that it was absolutely necessary to appoint somebody, and, on the whole, the plan adopted was considered to be the least likely to lead to troublesome questions. So long as the administration of public health is maintained on its present outlines, of which the inefficiency was from the very first pointed out to Mr. Stansfeld in preparing the original Public Health Bill by the most practical authorities on public health throughout the country, so long shall we continue to have an immense amount of money spent in trifling salaries and on little works, while comparatively small advance will be made in the prevention of disease and the saving of life.

## OBITUARY.

WALTER BARTON STOTT, M.R.C.S. Eng.

MR. WALTER BARTON STOTT died on April 8th, at the age of 75. He practised for many years in Manchester, and retired into private life in 1862. In his earlier days, he was Demonstrator of Anatomy at the school in Mount Street, conducted by the late Mr. Jordan, and afterwards in the Pine Street School. He had also the honour of being one of the founders in 1831 of the Children's Hospital in Manchester, in conjunction with the late Dr. Alexander.

## MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members on April 25th, 1878.

Bird, William Valentine, M.D. Aberdeen, L.R.C.P., Sydenham Hospital; Thomas Wemyss, M.B. London, St. Leonard's Hospital; Percy, M.D. Edinburgh, 6, Seymour Street; Gill, Stanley Augustine, Royal Lunatic Asylum, Liverpool; Sandby, Robert, M.D. Edinburgh, Birmingham; Savage, George Henry, M.D. London, L.R.C.P., Bethlem Hospital; Thorburn, John, M.D. Edinburgh, Manchester.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of Examiners, on April 25th; and, when eligible, will be admitted to the pass examination.

Messrs. William E. Winkell and Alexander Davidson, students of the London Hospital; William Sellers and Edward S. Jackson, of the Edinburgh School; Thomas P. Pemberton and Arthur L. Kingsland, of the Birmingham School; William Knott, of the Manchester School; John W. King, of St. Bartholomew's Hospital; Ignatius J. Rubin, of the Dublin School; Francis J. McDonnell, of the Charing Cross Hospital; and William M. Jennings, of the Newcastle School.

Twelve candidates were rejected.

The following gentlemen passed on April 26th.

Messrs. Edward A. Harbord, Alfred Lee, and William E. Alldridge, of the Birmingham School; Robert B. Knowles and James Thomson, of the Edinburgh School; Oswald G. D. Birtshaw, of the Bristol School; Robert Jones, of the Dublin School; James N. Richardson, of the Leeds School; William Layman, of the Manchester School; Frederick W. Martin, of the Liverpool and Charing Cross Hospitals; Edward G. Peck, of the Cambridge School; and John F. Mackenzie, of the Newcastle School.

Twelve candidates were rejected.

The following gentlemen passed on April 26th.

Messrs. Daniel E. Anderson, Sydney H. Henty, Edgar F. G. Morris, and James Norie, of University College; John C. R. Husband and David Harris, of the Leeds School; John J. Bewell and Leopold Burroughs, of Guy's Hospital; Charles Sanders and Howard H. Tooth, of St. Bartholomew's Hospital;

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### DO MEDICAL MEN PROMOTE INTemperance?

SIR,—The admirable spirit of Dr. Maclean's letter on the above in your JOURNAL of the 13th instant deserves the attention of the medical profession and the gratitude of every one interested in the great cause of temperance. As a very humble worker in this movement, I do sincerely pray that the question he has raised may lead to much common sense scientific Christian inquiry and action among medical men, leading them to expose the miserable fallacies by which our drinking habits have been so long bolstered up, and to discountenance "alcoholic prescription" except when "vitally necessary." And as to the vital necessity of using alcohol at all, the profession—so far as I am able to judge from their published opinions—represent a house divided against itself. But if it be allowed that it is vitally necessary to prescribe this dangerous article in certain cases, it must equally be allowed that in the past, at all events, such treatment has been far more common than necessary, and that the evil results are such as we resolutely declare them to be.

Now, sir, presuming that medical men allow the following facts, how can they hesitate on the course they should pursue in the "present distress"? There is not a shadow of doubt as to the fearful ravages which alcohol is making amongst us as a nation—drowning our morality, withering our physiology, blasting our happiness, damning our Christianity. Ten thousand times ten thousand proofs abound that alcohol is but a wasteful luxury or a dangerous drug. All, or nearly all, diseases and sickness can be successfully treated, and is so by an earnest section of the profession, without resorting to such a dangerous drug. Surely, sir, in the face of the first two undeniable facts—if we grant, for argument's sake, that the third is questionable—it behoves every medical man who is jealous for the honour of his profession, jealous for the bodily and spiritual welfare of his patients, and willing to do his duty in helping to remove the drink-curse which now afflicts our dear country, to at all events consider the possible evil results of any and every alcoholic stimulant which he may purpose to advise. If we are to accept the views of Dr. Alfred Carpenter on this most important question, as expressed by him in the *Church of England Temperance Chronicle* of this week, "medical men prescribe alcohol to a very great extent to humour their patients, and because from a pecuniary point of view they cannot afford to advise differently." If this be so, all I can reply is, so much the worse for the profession's honour and their patients' stomachs; so much the more must we, who do our best endeavours to promote the cause of temperance, unceasingly educate the public on this question, even though by such poor argument as was used "at a Western County, Church of England Temperance Society Meeting," to which Dr. Maclean specially refers.

If medical men will but conscientiously decide in every case, "Is alcohol vitally necessary here?" and prescribe accordingly, they will soon disarm us of arguments which, no doubt, sometimes are used with more zeal than discretion.—I am, etc.,  
Good Friday, 1878. TOM HALL, C.E.T.S., Ilfracombe.

THE following communications have been handed to the General Manager:—Dr. St. George, Lisburn; Messrs. MacLure and Macdonald, London; Messrs. Corby, Stacey, and Co., London; Dr. Lawrence Hamilton, London.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following were the questions on Anatomy and Physiology submitted to the candidates for the diploma of membership of the College of Surgeons on April 23rd, when they were required to answer at least four (including one of the first two) out of the six questions. 1. Mention the forces concerned in the venous circulation, and describe their action. 2. Give the minute anatomy of the nasal mucous membrane. 3. Describe the attachment of muscles to the tibia, and mention the nerve-supply of each. 4. Describe the anastomoses of the scapular arteries, and the dissection required to expose them. 5. Give the relations and distribution of the portio dura nerve outside the stylo-mastoid foramen. 6. The pharynx being opened from behind, describe the parts brought into view without further dissection.

#### MEDICAL WITNESSES.

SIR,—Having recently known of a case where a coroner received the evidence from a man who had no qualification, and who was not an assistant to any registered practitioner, and who had attended the case and was paid his fee, I wish to know if that coroner was acting legally in paying this quack, for he was nothing else, the fee? If not acting legally, would it be a service were I to lay the facts of the case before the Home Secretary?—I am, yours truly,  
CORNOR.

\*A coroner is bound by the Medical Witnesses' Act to summon as a witness and to take evidence only from a legally qualified medical practitioner, or one who is duly registered as such. In the case described by our correspondent the coroner acted illegally, not only in summoning an unregistered person, but in paying him the fee. The proper course for our correspondent to take is to lay the case before the magistrates who sit in quarter sessions. The fee which the coroner has thus illegally paid will be disallowed. This is the only mode in which he can be punished for his irregular conduct.

#### EAR-DISEASE AND LIFE-ASSURANCE.

SIR,—Having acceded to the request of the Bureau of the Section of Otolaryngology—President, Dr. Van Hock of Niemeu—of the International Congress of the Medical Sciences, to be held in September 1879, at Amsterdam, to act as reporter on the subject of "ear-disease with relation to life-assurance," I write to ask if you will be good enough to inform me if there be anything written on this subject other than the communications that have already appeared in the columns of the JOURNAL, and of which I am cognisant? Further will you allow me, through your columns, to ask those of my professional brethren who are advisers to assurance companies to inform me how they advise in respect to individuals who come before them as candidates for admission to the benefits of their respective offices, and who have a history (past or present) of an ear-disease, manifesting itself either by more or less of deafness alone, or by any ear-discharge, or by both together, or by the presence of old cicatrices over the mastoid; also, how they advise in respect to individuals who are totally deaf from inherited syphilis, and who may or may not be blind from the same cause. Replies to these queries sent to me direct will be regarded as a great favour; or, if you and your correspondents prefer it, I shall be glad to get them through the medium of your columns.—I am, yours very truly,  
JAS. PATTERSON CASSELLS.

2, Newton Terrace, Sauchiehall Street, Glasgow, April 22nd, 1878.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than Thursday, Twelve o'clock.

#### THE BRITISH MEDICAL JOURNAL.

SIR,—I wish to draw the attention of the members of our Association to a resolution unanimously passed at a recent meeting of the South Wales Branch at Carmarthen. It related to the publication of the JOURNAL. What I wish for, and every medical man to whom I have spoken upon the matter, is to have the leaves of the JOURNAL cut before it comes out of the printer's hands. It is the small worries in life that make it so uncomfortable, and this is one of them. Though it might appear too trivial almost to notice, yet its constant recurrence every week—the cutting of the pages—has so many times ruffled one's temper in the morning, that I have determined to do my best to rid myself of this trouble. I am told that possibly it will entail a small extra expense; if this be so, I shall be very pleased to pay for the boon. As the JOURNAL is the property of the members, surely we ought to have it published as the majority wish; hence I trust that other branches will take up this matter, and urge the Council to meet our views.—I am, sir, yours truly.

Morriston, April 1878.

E. RICE MORGAN.

\*The subject of Mr. Morgan's letter has been brought before the JOURNAL Committee, who have already had it under consideration, and who have endeavoured to make arrangements for the purpose in the new premises. The question is one of much difficulty and involving business details, which have been on several occasions carefully considered. One main difficulty arises out of the large issue of the JOURNAL, which amounts now to 1,500 copies a week, which have to be printed during Thursday night and rapidly issued on Friday morning.

DR. J. R. COTE writes to *New Remedies*: "Having accidentally discovered that tannin will deodorise indolism, I take pleasure in making known this fact; to you, and through you to the profession. I use it in equal parts, as an application to chancrels, and to old offensive ulcers."

#### CHRONIC ALCOHOLISM.

SIR,—Would any of your readers be good enough to state what they find most suitable in the tremors of chronic alcoholism, and also name any substitute for the constant craving for drink which exists? By doing so, they would oblige.  
April 16th, 1878. A CONSTANT READER.

\*As this is a very important question in practice and one of frequent occurrence, and as it is known that Dr. Lauder Brunton has given a great deal of attention to it, we have asked that physician to oblige us with his experience on the subject. He informs us that, according to his experience, "A Constant Reader" will find a combination of iron and nux vomica—say fifteen minims of the tincture of the perchloride and ten of tincture of nux vomica—one of the most efficacious remedies for the tremors of chronic alcoholism. If the stomach be deranged, as it very frequently is, the indigestion should be treated previously to the administration of iron, by giving ten grains of subnitrate or carbonate of bismuth with ten of magnesia, suspended with gum tragacanth. If there be any tendency to sleeplessness, or if the tremors should not rapidly disappear under the use of the iron and nux vomica alone, thirty or forty grains of bromide of potassium should be given at night. The chalybeate mixture already mentioned, either alone or with the addition of five or ten minims of tincture of capsicum, tends to alleviate the craving for drink. Another mixture recommended for this purpose consists of sulphate of iron, magnesia, and oil of cloves: a third consists of carbonate of ammonia in infusion of gentian, to be taken whenever the craving is felt. Should the craving come on at intervals of several weeks, with complete intermissions between, the case should be treated like one of epilepsy, by the administration of bromide of potassium.

THE fees named in Dr. J. Bennie's letter appear to be fair and proper charges.

#### PROFESSIONAL PUFFS.

WE are very sorry to see the notice of "most successful" operation of the removal of foreign bodies in the walls of the chest in the *Drogheda* which we published in the *Evening Journal*. We feel little doubt that such a notice must be as annoying to Dr. Adrien as it is distasteful to the profession. Editors of public journals should understand that such notices are distinctly injurious to the medical man whose name they couple with laudations of his skill, and medical men cannot be too careful to prevent injudicious friends from publishing worthless puffs of the kind. It is always obvious that a newspaper reporter cannot be a proper judge of surgical operations, and that any attempt to get such operations reported in the daily papers is an unfair and mischievous form of advertisement, which will always be discredited by the profession, with which it would greatly injure the professional reputation of any medical man to be supposed to have any connection.

SIR,—May I ask if the enclosed (leading notice in the *Edinburgh Chronicle*) is in accordance with professional obligations?—Yours,  
CHRISTIANE N.

P.S.—If the medical man referred to know nothing of the notice, he ought to have an opportunity of disclaiming it.

\*Many of our readers scarcely know the admirable work going on at the London Temperance Hospital, and fewer still the service which is being rendered by its skilful medical officers to the cause of temperance through the removal of the alcoholic treatment practised thereat. For instance, a man between fifty and sixty years of age only a month ago, by the operation of lithotomy, was relieved of a formidable calculus, measuring one inch in diameter, and which for years had rendered his life miserable. The operation was successfully performed by Dr. James Edmunds, and the patient is now so well that only the other day he walked two miles with ease. Other cases have been successfully treated. When operator and subject are thus both total abstainers, and the treatment always non-alcoholic, the success achieved deserves a conspicuous note in our columns.

DR. ROWSTON.—See BRITISH MEDICAL JOURNAL, September 23rd, 1877, page 368; and December 25th, 1875, page 225.

A CONSCIENTIOUS pharmacist, says the *Pharmaceutical Gazette*, receiving a prescription from a homeopathic physician in Vienna, for belladonna a tenth dilution, dispensed distilled water; but the medicine was sent back with a request to dilute it yet more, as it was still too powerful.

# NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

## GLANDERS IN THE HUMAN SUBJECT.

A DEATH from this disease took place at St. John's Hospital for Skin-Diseases on Good Friday. The man had complained for quite a month, previously of sickness and pains in the stomach, but these symptoms were possibly quite unconnected with the fatal disease. On March 25th and 26th, the patient was employed to drive a cart; immediately after which he absented himself from his work. On April 11th, he was seen by his employer, when he complained of being very unwell, and seemed to be labouring under a severe cold. On the Saturday following (the 13th), he entered at St. John's Hospital, but became rapidly worse; and when seen by Mr. Milton on the 15th, was evidently suffering from glanders in an advanced stage. The face was of an erysipelatous redness; a large portion of the right side of the nose was covered with a pulsataceous slough; the breathing was loud and brassy, and the appearance of the patient was like that of a man stupefied by some narcotic. The patient could scarcely stand, and complained of violent and constant pain in his head, saying he had not slept more than a quarter of an hour at a time for a fortnight. He was immediately ordered to bed, and taken into the hospital on Thursday, the 17th. He was supplied to an unlimited extent from the hospital with beef-tea, wine, and iced brandy, but vomiting and cramp came on the same evening; and though these seemed to improve after his admission, he died twenty hours afterwards, being quite sensible almost to the last minute. Towards the close, farcy-buds began to appear.

It has, so far, proved impossible to identify the animal from which the unfortunate man contracted the disease. The pony which he drove is in good health.

MR. J. B. EADE (Newcastle).—Paris Hospitals are open without fee to students; but those who wish to hold office as dressers or receive certificates must take an inscription at the Faculty, which costs a very small sum. Plenty of good pleasant lodgings will be found in the students' quarter, which is, indeed, now one of the most pleasant parts of Paris.

## MIDWIFERY ENGAGEMENTS.

SIR,—In reply to Dr. Burgess's letter, the matter appears to me to be very simple. If he wish an "engagement" to attend any case of midwifery, he should let the patient understand that his fee will be a certain sum, whether sent for or not; such fee to cover attendance for so many days, or to include so many after-visits; and that if the case be other than an ordinary one, the fee will be more (naming the sum). When a person calls to engage you to attend her in her confinement, I think myself the wisest plan is (amongst the guinea-fee class, at all events) simply to take a note of the time of expected confinement, as a matter of convenience to yourself, to let her understand that you will attend if in the way. If we wish to make the "engagement" binding on the patient, the latter has an equal right to make it binding upon us, and that might turn out very awkwardly for us at times.—Yours, etc.,

ALFRED SHEEN, M.D.

## RHAMNUS FRANGULA.

SIR,—A *profes* of Dr. Poulain's note on the *Rhamnus Frangula*, of which a *bon-ton* form, recently introduced by Mr. Baidon of Edinburgh, is likely to supplant, both in cheapness and efficacy, Grillon's Tamar Indien, allow me to add to its interest historically, if not etymologically. In Dr. William Turner's *Herbal* (1564, profusely illustrated, black letter), I find a short account of three kinds of *rhamnus*, from which the following is an interesting extract.

"Of these three kinds of *rhamnus*, when I was in Italy I sawe but one kinde, that is the thirde kinde which hath the round leaves, where as I sawe it, it was called *Christes thorn*, as though Christ had bene crowned with *rhamnus*. I never sawe it in Englande, and therefore I knowe no English name for it. But it may be called either *Christes thorn* or *buklar's thorne* (hence *Buckthorn*?) of the fashion of the fruyt or round rammes, of the broadnes of the leaves in comparison of the other two kinde, it groweth in the mounte Appennine a litle from Bononye . . . The leaves if they be laid to, are good for wild fires (*crispipelas*?) and greate hote inflammations, some holde that the bowes of it set at mennes dores, or windowes, do drive away sorcery, and enchantments that wyches and sorcerers do use against men."

What is "*ramnes*," and how linked with *ramus*, *ραμνος*, and *rhamnus*? The author describes the plant as a helgelush "with twiggies and roddes of 5 cubits high and full of prickles".—Yours, etc.,

C. ROTHWELL.

Bolton, April 16th, 1878.

## CONJOINT BOARDS.

SIR,—The letter of Dr. Gairdner on medical reform, in your issue of April 20th, merits attention. It affords proof of that which you have already pointed out—viz., the unwillingness of the Scotch corporations to yield to the long cherished desire for the establishment of conjoint boards. In favour of the continuance of the present system of examination in Scotland, Dr. Gairdner, speaking of the Royal College of Surgeons of Edinburgh, says "its diploma has from first to last been granted only after an education much more complete than that required by any single corporation in England". While this can scarcely be admitted, even of its diploma for membership, I would ask whether it is not a fact that the fellowship of that College is granted to men without any examination at all, and simply on the recommendation of two or more eminent surgeons? If this be so, how can Dr. Gairdner put forth so bold an assertion as that contained in his letter? In a country town well known to myself, and where only eight medical men practise, two of that number hold the Fellowship of the Edinburgh College of Surgeons, and that too, without having ever been subjected to an examination, writing a thesis, or even putting in an appearance at the College. This, sir, shows how misleading to the public are the qualifications given by the Scottish examining boards.

Much might be written about the title of Doctor obtainable in Scotland and Ireland after an examination in no respect more searching than that made at the London College of Physicians or the Apothecaries' Society, but which places its recipient on a scale of advantage in public estimation higher than that of either the L.R.C.P. or L.S.A. I must, however, refrain.

I lay all means let each member of the British Medical Association use whatever influence he possesses with the legislature to promote the compulsory establishment of joint boards for the three kingdoms.—I am, sir, yours faithfully,

April 20th, 1878.

M.R.C.S. Eng., L.S.A.

## RESIDENCES FOR INVALIDS.

In further reply to "Hygeia," we would remark that it is impossible within our space to enter into questions of drainage and water-supply in detail. The condition, especially of the former, varies in different portions and different houses of the same

general locality. In the immediate vicinity of London, salubrious spots are to be found, perhaps had, at Wimbledon, parts of Upper Norwood, at Highgate, and at Hampstead; also, a little further off, on the higher points near Surbiton. At a greater distance, we consider Sunninghill and Ascot to have one of the best climates near London, or in England, and think them superior to Windsor or Slough, the latter of which, and part of the former, lie rather low. They are not, perhaps, so cheerful or convenient for persons of moderate means as Windsor or Slough. Tunbridge Wells is a very healthy and cheerful town, very superior to its neighbour, Tunbridge, which lies low. In central England, Malvern is most highly to be recommended, and is far superior to any place of the kind we know.

## SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

SIR,—I am directed to inform you that, at the annual general meeting of the Society, held on April 24th, a vote of thanks was carried unanimously to the Editors of the Medical Journals, "for their kindness in forwarding in every way possible the objects of the Society".—I am, sir, your obedient servant,

April 26th, 1878.

J. B. BLACKETT, Secretary.

## MEDICAL DEGREES.

SIR,—I think Dr. Jacobs's letter respecting the title of "Doctor" in your issue of the 27th instant is wide of the mark. The real grievance of the English medical men is, that they have not the same facilities offered them for obtaining a degree in their native land as their Scotch and Irish brethren have, and this is certainly very hard; hence the majority of men educated in England prefer a licence from one of our recognised corporations to a degree from an university across the Border or Channel. And again, another great grievance we experience is that, being possessed of English licences, we are debarred from using the title of "Dr." (by etiquette), while our neighbour may so style himself, having obtained a Scotch or Irish L.R.C.P. This is most unjust to the profession, and also to the public generally. I maintain that the Duke of Richmond's Bill should either enact that all practitioners should be styled "Dr.", not "M.D.", or that none should be so styled except they hold the degree of M.D.

Before leaving this important subject, I would again point out the difficulties that lie in the way of a student who would graduate at an English University as compared with those of Scotland and Ireland, feeling sure that some radical reform will shortly be found necessary.—I am, sir, yours truly,

April 26th, 1878.

ENGLISH LICENTIATE.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fishers Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

## COMMUNICATIONS, LETTERS, etc., have been received from:—

Sir William Smart, Dresden; Mr. G. Callender, London; Dr. W. T. Gairdner, Glasgow; Dr. C. Theodore Williams, London; Mr. F. A. Southam, Manchester; Mr. Richard Barwell, London; Dr. J. T. Arlidge, Stoke-on-Trent; Dr. George Johnson, London; Dr. T. Cranston, Chichester; Mr. J. Blanchard, London; Mr. Balmano Squire, London; Messrs. *Effect of Chloral on Atropine.*

No.	Weight.	Dose of Chloral.	Dose of Atropia.	Result.
104	1 pound 9 ounces	8 grains	12 grains	Death in ten minutes
105	2 " 7 "	12 "	18 "	Recovery
106	1 " 9 "	10 "	12 "	Death in two hours
107	1 " 9 "	10 "	12 "	" five hours
108	1 " 11 "	6 "	12 "	" one hour and a half
109	1 " 10 $\frac{1}{2}$ "	3 "	12 "	" one hour

From this it would appear that chloral only somewhat delayed the fatal advent in atropine-poisoning, as seen in the last three experiments. No. 105 after a week got other eighteen grains of atropia without any chloral, and again recovered.

It was next thought desirable to test the effect of strychnia upon aconite-poisoning.

*Effects of Fatal Doses of Strychnine upon Fatal Doses of Aconitine.*

No.	Weight.	Dose of Aconitine.	Interval.	Dose of Strychnia.	Result.
110	3 pounds	1-300th of a grain	Twenty minutes	1-100th of a grain	Death
111	"	1-120th "	"	Unknown	"

In the first of these two experiments, after a fatal dose of aconitine, with an interval of twenty minutes, the minimum fatal dose of strychnia (according to Dr. Bennett) was injected. The aconitine symptoms were much relieved; but the rabbit died in a strychnia-fit. To the second an unknown amount of strychnia was administered, as a quantity escaped through a leak in the syringe. No influence, or very little, was exercised over the course of aconitine-poisoning.

It has not been possible to carry out a complete series of experiments on the antagonism of strychnia and aconitine in the rabbit; but the subject appears worth pursuing, as the following experiments would indicate.

No.	Weight.	Dose of Aconitine.	Dose of Strychnia.	Result.
112	2 pounds 11 ounces	1-300th of a grain	1-150th of a grain	Death in 15 minutes
113	2 " 9 "	1-300th "	1-50th "	Recovery
114	5 " 2 "	1-200th "	1-50th "	"
115	2 " 0 "	1-400th "	1-50th "	Death in 30 minutes

The deaths were both due to strychnia. No. 113 had a convulsion twenty minutes after the injection of the strychnia, but recovered without any signs of aconite-poisoning. No. 114 had no severe symptom of any kind. No rabbit would survive 1-200th of a grain of aconitine given alone.

These experiments, so far as they go, are at least suggestive. They were abruptly brought to a close by the passing of the Vivisection Act.

## SUMMARY.

1. The minimum lethal dose of Morson's aconitine for a guinea-pig of 1 $\frac{1}{2}$  lbs. weight is 1-1200th of a grain; for a rabbit of 1 $\frac{1}{2}$  lbs. weight, 1-400th of a grain; for a 3 lb. rabbit, 1-300th of a grain; the difference being due, probably, rather to age than to size. The younger rabbit took a comparatively larger dose.
2. The minimum lethal dose of digitaline (Smith's) is nearly one grain to the pound weight in the rabbit.
3. The simultaneous administration of digitaline and aconitine affords no protection.
4. If digitalis be given in sufficient dose and a sufficient time (from five to nine hours) before a lethal dose of aconitine is administered, a distinct protection is afforded.
5. When the digitaline is given at a less interval than five hours, the toxic power of aconitine is intensified.
6. Small doses of atropine, given before lethal doses of aconitine, exercise a decided protective influence.
7. Small doses of aconitine do not appear to exercise any influence over lethal doses of atropine.
8. Atropine in four-grain doses effectually antagonises lethal doses of aconitine, up to sixteen minutes after the administration of the latter.
9. Atropine exercises no like influence over lethal doses of chloral.
10. Strychnia exercises a potent influence over lethal doses of aconitine; but the experiments are too few to warrant very decided conclusions.

# VIII.—REPORT ON THE PHYSIOLOGICAL ACTION OF THE CHINOLINE AND PYRIDINE SERIES OF COMPOUNDS.

By JOHN G. MCKENDRICK, M.D., F.R.S.E.,

Professor of the Institutes of Medicine in the University of Glasgow; etc.

It was first shown by Gerhardt\* that when either quinine, cinchonine, or strychnine is distilled with caustic potash, each of these bases yields two homologous series of bases, named the pyridine and chinoline series. It has also been shown by Anderson† and Greville Williams‡ that bases isomeric with these are obtained by the destructive distillation of coal or from Dippel's oil. Greville Williams has also pointed out that chinoline obtained from coal-tar differs in some respects from that got from cinchonine.

It became a matter of physiological interest to ascertain (1) the action on the animal body of the various members of the series; (2) whether there was any difference in this respect between the members of the series obtained from cinchonine and those got from tar; (3) whether, and if so how, both as regards extent and character, the physiological action of these bases differed from that of the original alkaloidal bodies; (4) whether the action of the methyl and ethyl compounds of the substances was different from that of the substances themselves; (5) whether any facts could be ascertained generally which would throw light on the interesting problem of the relation between the chemical constitution of active substances and their physiological action.

## I.—HISTORY OF THE RESEARCH.

This investigation has been carried on at intervals during the past four years. In the first instance, I had the able co-operation of Professor James Dewar, now of Cambridge; and the results of our work were communicated to the Royal Society in 1875.§ By Professor Dewar's removal to Cambridge, the investigation was arrested for a time. Soon after my own removal to Glasgow, I obtained the valuable aid of Dr. W. Ramsay, Tutorial Assistant of Chemistry in the University of Glasgow, whose writings on the chemistry of picoline and its derivatives are well known. In such a research as the present, the co-operation of the chemist with the physiologist is indispensable; and I consider myself as having been singularly fortunate in having associated with me such chemists as Professor Dewar and Dr. Ramsay, both of whom have paid great attention to the chemistry of the compounds under consideration.

## II.—CHEMICAL RELATIONS OF THE CHINOLINE AND PYRIDINE SERIES OF BASES.

*a. Homologues of Chinoline.*—Without entering into details regarding the theoretical chemical constitution of these substances, it is sufficient to state here that when cinchonine or quinine is distilled with potassium hydrate, various bases may be obtained, at different boiling-points. Greville Williams showed, however, that no amount of fractional distillation will furnish chemically pure members of this series. Thus, with the exception of chinoline itself, the fluids we used in this research were really mixtures of bases obtained at various boiling-points. The laborious method of isolating by fractional crystallisation was not employed. These bases are:

Name.	Empirical Formula.	Boiling Point.
Chinoline	$C_9H_7N$	...
Lepidine	$C_{10}H_9N$	...
Dispoline	$C_{11}H_{11}N$	200 to 280 deg. Cent.
Tetrahioline	$C_{12}H_{13}N$	280 to 300 deg. Cent.
Pentahioline	$C_{13}H_{15}N$	Above 300 Cent. These can only be separated by fractional crystallisation of their platinum salts.
Isoline...	$C_{14}H_{17}N$	
Etidine	$C_{15}H_{19}N$	
Validine	$C_{16}H_{21}N$	

It will be observed that we have here a homologous series of compounds passing from the lower to the higher by successive increments of  $CH_2$ . A similar series of bodies may be obtained from heavy coal-tar oil. All of these bases unite with acids forming salts.

*b. Homologues of Pyridine.*—Pyridine is a substance discovered by Anderson|| in an investigation of bone-oil. Williams¶ found it in the distillation of bituminous shale, and among the alkaloids produced by the destructive distillation of cinchonine. These bases are separable by fractional distillation. They are:

Name.	Empirical Formula.	Boiling Point.
Pyridine	$C_5H_5N$	115 deg. Cent.
Picoline	$C_6H_7N$	134 deg. "
Lotidine	$C_7H_9N$	154 deg. "

Rubidine ... ..	$C_{11} H_{17} N$ ... ..	230 deg. "
Viridine ... ..	$C_{12} H_{19} N$ ... ..	251 deg. "

c. *Addition-Derivatives of Chinoline.*\*—Greville Williams† first succeeded in obtaining compounds, which he termed the hydrodates of methyl-chinoline, ethyl-chinoline, and amyl-chinoline. They are prepared by heating in a sealed tube chinoline with iodide of methyl, iodide of ethyl, or iodide of amyl, and they are represented by the following formulæ:

*Chinoline,  $C_9 H_7 N$ .*

Methyl-chinoline ... ..	$C_{10} H_{10} N$ , or $C_9 H_7 N \cdot CH_3$
Ethyl-chinoline ... ..	$C_{11} H_{12} N$ , or $C_9 H_7 N \cdot C_2 H_5$
Amyl-chinoline ... ..	$C_{14} H_{18} N$ , or $C_9 H_7 N \cdot C_5 H_{11}$

It will be observed that the molecular weight of these addition-compounds is greater than that of chinoline itself. The hydriodides and sulphates were the salts always employed in this research. The substitution-derivatives of the other members of the chinoline series have not been investigated; but it is important to observe that their properties are tolerably well known to chemists.

d. *Addition-Derivatives of Pyridine Series.*—Similar addition-compounds belong to the pyridine series. Of these, the methyl-iodide of pyridine was the only one examined in this inquiry. The addition-derivatives of picoline, one of the best known members of the series since the researches of Anderson, are as follows:

*Picoline,  $C_6 H_7 N$ .*

Methyl-picoline ... ..	$C_7 H_{10} N$ , or $C_6 H_7 N \cdot CH_3$
Ethyl-picoline ... ..	$C_8 H_{12} N$ , or $C_6 H_7 N \cdot C_2 H_5$
Amyl-picoline ... ..	$C_{11} H_{15} N$ , or $C_6 H_7 N \cdot C_5 H_{11}$
Allyl-bicoline ... ..	$C_9 H_{12} N$ , or $C_6 H_7 N \cdot C_3 H_5$

The hydriodide and sulphate were the salts employed.

e. *Polymeric Bases of Pyridine Series.*—By the action of sodium on pyridine, Anderson† succeeded in obtaining dipyridine, a base polymeric with pyridine and represented by the formula  $C_{10} H_{10} N_2$ , that is, twice the number of atoms in pyridine,  $C_5 H_5 N$ . In a similar manner, di- and even tri-picoline (?) may be obtained, having the formula  $C_{12} H_{14} N_2$  and  $C_{18} H_{21} N_3$ . By heating these compounds with iodide of methyl or ethyl in sealed tubes, dipyridine methyl- or ethyl-iodide and dipicoline methyl- or ethyl-iodide may be produced, thus remarkably increasing the molecular weight. Thus:

Pyridine ... ..	$C_5 H_5 N$	Picoline ... ..	$C_6 H_7 N$
Dipyridine ... ..	$C_{10} H_{10} N_2$	Dipicoline ... ..	$C_{12} H_{14} N_2$
Dipyridine ethyl-iodide ... ..	...	...	$C_{12} H_{15} N_2 I$ , or $C_{10} H_{10} N_2 \cdot C_2 H_5 I$
Dipicoline ethyl-iodide ... ..	...	...	$C_{14} H_{19} N_2 I$ , or $C_{12} H_{14} N_2 \cdot C_2 H_5 I$

f. *Dicarboxypyridenic Acid.*—In a research on the pyridine series of bases, Dewar‡ discovered an acid to which he gave the above name. It is represented by  $C_7 H_5 N_5 O_4$ . Dr. Ramsay prepared a quantity for the purposes of this research, and the following salts were examined:

Dicarboxypyridenate of ammonia ... ..	$(NH_4)_2 C_7 H_5 N_5 O_4$
Dicarboxypyridenate of soda ... ..	$Na_2 C_7 H_5 N_5 O_4$
Dicarboxypyridenic methyl-ether ... ..	$(CH_3)_2 C_7 H_5 N_5 O_4$

Dewar§ has recently discovered that the members of the chinoline series yield on oxidation a similar acid, to which he has given the name of leucolinic acid. The physiological properties of this substance have not yet been examined.

The formulæ of these compounds, as compared with various alkaloids, will be seen at a glance in the following table:

Name.	Empirical Formula.	Alkaloid.	Empirical Formula.
Pyridine ... ..	$C_5 H_5 N$	Curarine ... ..	$C_{10} H_{13} N$
Picoline ... ..	$C_6 H_7 N$	Conine ... ..	$C_8 H_{12} N$
Lutidine ... ..	$C_7 H_9 N$	Caffeine and theine ... ..	$C_8 H_{10} N_4 O_2$
Collidine ... ..	$C_8 H_{11} N$	Nicotine ... ..	$C_{10} H_{14} N_2$
Parvoline, etc. ... ..	$C_9 H_{13} N$	Santonine ... ..	$C_{15} H_{18} O_5$
Polymeric Pyridine Bases.	$C_{10} H_{10} N_2$	Physostigmine ... ..	$C_{15} H_{21} N_8 O_2$
Dipicoline ... ..	$C_{12} H_{14} N_2$	Morphine ... ..	$C_{17} H_{19} NO_3$
Tripicoline ... ..	$C_{18} H_{21} N_3$	Atropine ... ..	$C_{17} H_{23} NO_3$
Methyl picoline ... ..	$C_7 H_{10} N$	Codeine ... ..	$C_{18} H_{21} NO_3$
Ethyl picoline ... ..	$C_8 H_{12} N$	Thebaine ... ..	$C_{19} H_{21} NO_3$
Amyl picoline ... ..	$C_{11} H_{18} N$	Bebeerine ... ..	$C_{19} H_{21} NO_3$
Allyl picoline ... ..	$C_9 H_{12} N$	Quinine ... ..	$C_{20} H_{24} N_2 O_2$
Dipyridine methyl ... ..	$C_{11} H_{13} N_2$	Cinchonine ... ..	$C_{20} H_{24} N_2 O_2$
Dipyridine ethyl ... ..	$C_{12} H_{15} N_2$	Narceine ... ..	$C_{23} H_{29} NO_3$
Dipicoline ethyl ... ..	$C_{14} H_{19} N_2$	Brucine ... ..	$C_{23} H_{26} N_2 O_4$

\* It has been thought advisable to alter the name "substitution-derivatives" to "addition-derivatives", for it is evident that the hydrogen of the base is not replaced by methyl, ethyl, etc.—as, for instance,  $C_5 H_4 (CH_3) N$ : and such compounds are really analogous to true salts, such as the hydrochloride, hydriodide, etc. Compare  $C_5 H_5 N \cdot HI$ , with  $C_5 H_5 N \cdot CH_3 I$  and with  $C_5 H_5 N \cdot C_2 H_5 I$ .

### III.—METHOD OF THE RESEARCH.

The substance first examined was chinoline obtained from cinchonine. It was employed both as sulphate and hydrochloride, dissolved in water, and introduced by subcutaneous injection into the animal. The strength of the solution employed in this and in all other instances was one part of the base to twenty parts of water. Its physiological action was tested on frogs, mice, rabbits, guinea-pigs, cats, dogs, and man; but, as the effects were found to be similar in all of these instances, the majority of the observations were made on rabbits. After having noted the effects of chinoline, we next studied, by the same method, the action of hydrochlorides of the bases distilling off at higher temperatures, including such bases as lepidine, dispoline, tetrahiroline, etc. We then examined the pyridine series, beginning with pyridine itself, and passing upwards to bases obtained at still higher boiling-points, such as picoline, lutidine, etc. The investigation was directed to the action of condensed bases, such as dipyridine, dipicoline, etc.; and the effects of these substances were compared with those produced by the members of the chinoline series and among themselves. We then proceeded to examine the action of the addition-derivatives, and of dicarbopyridenic acid. So far as we could observe, there was no difference as regards physiological action between bases obtained from cinchonine and others got from tar.

### IV.—PHYSIOLOGICAL EFFECTS OF HYDROCHLORIDE OF CHINOLINE ( $C_9 H_7 N \cdot H Cl$ ).

The administration, by subcutaneous injection, of one grain and a quarter for every pound of weight into a healthy rabbit produced the following effects. In four or five minutes, the animal appeared to become drowsy, was unwilling to move; but, when pushed, locomotion was not affected. Both the pulsations of the heart and the respiratory movements were slightly increased in frequency at this stage. The drowsiness increased, and in a few minutes more the animal sank on its abdomen and remained motionless, with the eyes widely opened. It was now gently turned over on its back or side, and it remained in that unnatural position. Still later, there was complete anæsthesia. At no period was there any hyperæsthesia. Reflex functions were also in abeyance so far that they could not be excited by pinching or pricking, but irritation by a faradic current caused feeble movements. The animal appeared to be unconscious of loud sounds. The pupil was normal as regards size, and it contracted readily when exposed to a strong light. The reflex movements of the eyelid were not lost until the animal was in a state of deep stupor from an overdose. The respirations were now much fewer in number, and of less depth than normal. The heart still acted vigorously, but the pulsations were decreased in number by about one-sixth. After remaining motionless in that condition for a period of three or perhaps four hours, the rabbit slowly recovered, raised its head from the table, began to move about, and frequently ate food placed before it. It recovered completely from the dose above indicated, without any bad symptom supervening. A dose of two grains or two grains and a half per pound weight was usually lethal. If, at the end of three hours, the animal showed no indications towards recovery, it apparently sank in a state of profound insensibility, the heart-pulsations became feebler, and the respirations more and more shallow, until they were barely perceptible. Death ensued without convulsions. The temperature of the body fell six to eight degrees below the normal. An examination of the body, made immediately after death, showed the following appearances: (1) The vessels on the surface of the brain were somewhat congested; the substance of the brain itself did not exhibit any increase of vascularity; (2) the lungs were congested, more especially along the borders; (3) the heart was in a state of diastole and full of dark-coloured blood; (4) the veins in the mesentery and the larger vessels on the intestine were much congested; (5) the liver showed numerous minute ring-like congestions, indicating congestion of the portal system; (6) the kidneys and other abdominal and pelvic viscera were normal in appearance; and (7) the urine in the bladder contained no albumen or sugar.

From these symptoms and *post mortem* appearances, and from special methods of experiment, we draw the following conclusions regarding the action of hydrochloride of chinoline.

1. *Action on the Nervous System.*—The action is chiefly, if not altogether, on the nerve-centres, and not on the nerves or on their peripheral terminations. When the sciatic nerve is irritated by very feeble faradic currents, it manifests no diminution of sensibility, and the muscles supplied by the nerve contract with apparently their normal energy. The nerves of a frog killed by hydrochloride of chinoline show all the properties of nerves obtained from a non-poisoned animal. The sympathetic system of nerves is not usually affected to any appreciable extent, as evidenced by the normal condition of the pupil, the absence of dilatation of the vessels in the ear (consequent on paralysis of the vaso-motor system), and by the fact that, in an animal deeply under the influence of chinoline, the phenomena following section and irritation of the sympathetic in the neck of a rabbit take place to the same extent and in the same order as in a non-poisoned animal. In several instances we have observed dilatation of the vessels of the ear and slight contraction of the pupil; but these, from their rare occurrence, appear to be exceptional. No change was observed in the action of the pneumogastric nerve, so far as could be ascertained by the effect on the heart produced by faradic irritation of that nerve. We have observed no symptoms leading us to suspect irritation or paralysis of the centres in the cerebellum, or in the ganglia at the base of the brain; but in lethal doses the respiratory centres in the medulla oblongata become gradually affected, as shown by the diminution of the respiratory movements both in force and in frequency. The motor columns of the spinal cord do not lose their power of conduction from

the encephalon to various parts of the body, because, on irritating with a weak faradic current the end of the cord in a rabbit decapitated while deeply under the influence of the substance, powerful convulsive movements ensued. The reflex activity of the cord is much weakened, inasmuch as it cannot be excited by pinching or pricking; but it is not entirely lost, because it may be excited by faradic stimulation; and it has been observed in several experiments that strychnine, subcutaneously injected into a rabbit prostrate with hydrochlorate of chinoline, is followed by its usual physiological effects. It appears, therefore, that the substance acts chiefly on the sensory and motor centres in the cerebral hemispheres, weakening or removing all consciousness of external impressions and also all voluntary acts.

2. *Action on the Respiratory and Circulatory Systems.*—In the first instance, the action of the heart and the respiratory movements are increased, but afterwards they are much diminished, and death appears to be the result of these processes becoming weaker and weaker, until they cease altogether. The increased action observed at first is probably due to the excitement of the animal consequent on the injection of fluid beneath the skin. So soon as the substance acts through the blood on the nerve-centres, the action of both systems is weakened. We regard this weakening as due to an action on an encephalic centre, for the two following reasons: first, because irritation of the sympathetic and pneumogastric nerves in the neck of a rabbit completely under the influence of hydrochloride of chinoline produces acceleration and retardation of the heart's action respectively, as occurs in a healthy animal; and secondly, when the heart of a frog was treated according to Coats's method, with serum containing three per cent. of chinoline, no effect was observed. These experiments seem to indicate clearly that the substance acts on the encephalic centres, and through them on the heart and respiratory organs. The action of the heart finally ceases, probably by its textures being supplied with only venous blood.

3. *Action in lowering the Temperature of the Body.*—It was found, in three instances in which minute differences of temperature were observed at intervals of one minute, during a period of one hour before and one hour after the subcutaneous injection of hydrochloride of chinoline, that the substance produced a gradual and uniform fall of temperature to the extent of from six to eight degrees below the normal. In all of these instances the animal recovered from the effects, and, during recovery, the temperature slowly rose to its normal limit. This action we regard as of considerable importance. It is probably to be explained by interference with nutritional changes between the blood and the tissues, and also by the diminution, both in frequency and depth, of the respiratory movements.

4. *Action on the Dog.*—In 1875, three experiments were made on dogs. The effects were precisely similar to those already described, with the exception that nausea and vomiting occurred soon after the introduction of the substance beneath the skin, and that there was considerable cerebral excitement before the occurrence of stupor.

5. *Action in the Monkey.*—Two experiments were made on monkeys, one in 1875 and the other in 1876. The effects were the same as in the dog. One animal (a small macaque), used in 1875, died, after a dose of eight grains, in profound coma lasting nearly seven hours, although artificial respiration was kept up during a considerable portion of the time. The other, used in 1876, was a stronger animal, and recovered from a comatose condition lasting ten hours, after a dose of ten grains.

6. *Action in Man.*—The reporter on two occasions swallowed twelve grains of the substance, but the nausea was such as to forbid any further prosecution of the experiment. The only other symptom noticed was slight drowsiness.

7. *Remarks.*—If we compare the effects of chinoline on the rabbit with those on the dog, monkey, and on man, the chief fact to be noticed is the occurrence of nausea and of vomiting in the latter. This shuts out the hope at one time entertained that the substance might be employed to produce artificial stupor lasting for several hours continuously, unless, perhaps, the nauseating effect might be counteracted by combination with other substances. For physiological purposes, however, in experiments on frogs, birds, rats, and rabbits, it is very serviceable, inasmuch as it is possible to maintain this state of stupor and anæsthesia for several hours without the employment of artificial respiration. It was also observed that chinoline caused cerebral excitement in the first instance in the cat, dog, and monkey, whereas in the rabbit there is no excitement at any period.

#### V.—ACTION OF HYDROCHLORIDES OF THE HIGHER BASES OF THE CHINOLINE SERIES.

1. *Bases obtained by Distillation between 200° and 280° C. Lepidine, etc.,  $C_{10}H_9N$ .*—These bases produced the same general action as chinoline, with the exceptions (1) that the dose required to produce a state of complete stupor was somewhat smaller than in the case of chinoline; and (2) that, after a state of stupor had been produced, the animal was less likely to recover, while it was observed that frequently before death there were jactitations of one or other of the limbs, and convulsive twitchings about the mouth.

2. *Bases obtained by Distillation between 280° and 300° C. Dispoline, etc.,  $C_{11}H_{11}N$ .*—It was now observed that the symptoms following subcutaneous injection were considerably different from those of chinoline. One grain for each pound weight of the rabbit produced, in about five minutes, apparent uneasiness, side to side movements of the head, with a tendency occasionally to move backwards. This condition continued for three or four minutes, when the animal lay flat on its abdomen with its legs outspread. It was not in a state of complete unconsciousness. There was no anæsthesia. In several instances, there were convulsive twitchings of the limbs, grinding of the teeth, and a slight tendency to opisthotonos. The lethal dose was smaller than in the case of chinoline. The effects were a longer time in appearing, and they had more of a spinal than of a cerebral character.

3. *Bases obtained by Distillation above 300° C. Tetrahiroline, etc.,  $C_{12}H_{13}N$ .*—These were found to be still more active. A dose of three-quarters of a grain per pound weight produced, in eight or ten minutes after it had been subcutaneously injected, violent convulsions, and was almost invariably fatal. During the first five minutes after the introduction of the poison, no marked symptoms were noticed. At the end of this time, the animal became uneasy, ran forwards in an excited manner, and then fell over on its side. The convulsions which ensued were similar to those produced by the action of large doses of quinine or cinchonine. They did not resemble the tetanic spasms produced by strychnia, as they were not excited by peripheral irritations; but they had an epileptiform character, consisting of irregular jactitations of the limbs, crunching of the teeth, movements of the eyeballs, pawing movements of the fore limbs, etc. The animal seemed to be semiconscious throughout. It was still susceptible to pain.

4. *General Results as to Physiological Action of Chinoline Series.*—A consideration of the effects just described indicates

that, as we ascend from the lower to the higher members of the chinoline series of bases, the physiological action becomes modified as follows.

1. The action on the sensory centres of the encephalon becomes less marked, until, in the highest group, there is no unconsciousness, but only slight stupor.
2. The actions of the motor centres of the encephalon and spinal cord are not affected in the lowest group, but become gradually more and more involved as we proceed upwards, until, in the highest group, we have substances producing powerful convulsions.
3. The lethal dose is smaller for the higher than for the lower members of the series.

#### VI.—ACTION OF HYDROCHLORIDES OF THE BASES IN THE PYRIDINE SERIES.

The physiological action of the bases of the pyridine series was next examined in the following order.

1. *Pyridine*,  $C_5H_5N$ .—The hydrochloride of this base produced no effects, even in doses of six grains per pound weight, other than slight excitement and acceleration of the pulse and of the respiratory movements. The animal, judging from its gait and demeanour, appeared to be in a state analogous to intoxication. It recovered without any bad effects.
2. *Picoline*,  $C_6H_7N$ .—The substance was employed both in the form of the base dissolved in water and as a hydrochloride. The salt was found to be more active physiologically than the base, but the kind of action was the same. The general effect was to produce, with a dose of three grains per pound weight, in the first place, general excitement and a full bounding pulse. This state was followed by a drowsy condition, which did not pass, with even a dose of six grains per pound weight, into complete stupor. The rabbit could always be readily aroused. While in the drowsy condition, the pulse fell in frequency and volume, and the respirations became feebler. The results we have obtained differ somewhat from those described by Vohl and Eulenber<sup>\*</sup> in a paper on the Physiological Action of Tobacco when used as a Narcotic, with especial reference to the Constituents of Tobacco-Smoke, of which picoline is one. The only explanation we can offer is that these gentlemen must have experimented with impure specimens of picoline.
3. *Lutidine*,  $C_7H_9N$ .—The effects were similar to those produced by picoline, only more marked. A dose of three grains per pound weight produced deep stupor, from which the animal could not be aroused. It remained in this condition for a period of from two to three hours. The pulsations of the heart were much reduced in volume, but only slightly in frequency; but it was clearly observable that the respirations were much less deep than in the natural condition, and they were reduced in frequency by about one-third. In a case of death from a lethal dose of four grains per pound, there was venous congestion in all parts of the body, but the heart was still feebly pulsating. It was observed that the blood had a peculiar dark chocolate-brown appearance. Examined with the spectroscope, it showed the two bands of oxyhæmoglobin.
4. *Collidine*,  $C_8H_{11}N$ .—Collidine was still more active in its effects. With a dose of a grain and a half per pound weight, the animal rapidly sank into a state of profound stupor, from which it could not be aroused. Anaesthesia was complete. The pulsations of the heart and the respirations became more and more feeble, until death ensued in about twenty minutes after the dose, apparently in consequence of failure of respiration. There were no twitchings or convulsions. The subcutaneous injection into a rabbit of one-eightieth of a grain of strychnine was followed by the usual physiological effects of that substance.
5. *The Higher Pyridine Bases obtained by Distillation above 200° C., such as Parvoline*,  $C_9H_{13}N$ , etc.—These were found to be still more active; but the effects were of the same nature as those just described. The lethal dose was found to be about three-quarters of a grain per pound weight. In two or three minutes, the animal sank on its abdomen; when pushed, could move with difficulty; respirations were rapid and irregular. It then lay on its side, and in four or five minutes died, apparently in an asphyxiated condition. There were no convulsive spasms or twitchings. This substance was lethal in much smaller doses than the lower bases of the chinoline series.
6. *General Results as to Physiological Action of the Pyridine Series.*—The pyridine series of compounds thus showed a gradual increase in activity of physiological action. The lowest of the series produced merely excitement from irritation of the encephalic nervous centres, while the highest produced paralysis of these nervous centres. There was no irritation of the spinal cord causing increased reflex activity. Death ensued from gradual failure of the respiratory movements, leading to asphyxia. The action of the higher pyridines was thus somewhat analogous to the lowest of the chinoline series, with this exception, that the pyridine compounds tended to cause death by asphyxia. It is to be noted also that the higher bases of the pyridine series were lethal in somewhat less than one-half of the dose required to destroy life by the lower members of the chinoline series.

#### VII.—ACTION OF HYDROCHLORATES OF THE CONDENSED OR POLYMERIC BASES OF THE PYRIDINE SERIES.

Considering the close analogy in chemical composition between the polymeric bases of pyridine and certain natural bases, such as nicotine, it became of importance to examine the physiological action of these bases, which were prepared, according to Anderson's method, by the action of sodium on pyridine, picoline, etc. The following were the effects observed after the subcutaneous injection of one grain of the hydriodide of dipicoline per pound weight into a rabbit. The animal remained quiet for a period varying from four to eight minutes, when it suddenly appeared uneasy, ran forwards as on tiptoe, with the back arched, and, falling on its side, became violently convulsed. The convulsions continued, almost without intermission, for three or four minutes, when death ensued. So far as could be observed, consciousness was not lost until immediately before death. The character of the convulsions resembled that of those produced by cinchonine or quinine, except that the tendency to backward movements, with the fore-legs extended, was not so marked; they also resembled those produced by salts of the higher members of the chinoline series, but they were more severe than in the latter. The hydrochlorides of two condensed bases of this kind were employed in the first instance—the first made from pyridine, and the other from picoline. The formulæ for these are: hydrochloride of dipyridine,  $C_{10}H_{11}N_2 \cdot 2HCl$ ; and hydrochloride of dipicoline,  $C_{12}H_{13}N_2 \cdot 2HCl$ . The latter was found to be the more active of the two, but the actions were identical in character. The hydriodides were also used, and were found to be more active than the hydrochlorides.

<sup>\*</sup> Vohl and Eulenber, *Ar. für die Pharm.* [2], vol. cxlvii, pp. 130-166.

## VIII.—ACTION OF THE ADDITION-DERIVATIVES OF CHINOLINE.

These were—

Methyl-chinoline ...	...	...	...	...	...	$C_9H_7N \cdot CH_3$ or $C_{10}H_8N$
Ethyl-chinoline ...	...	...	...	...	...	$C_9H_7N \cdot C_2H_5$ or $C_{11}H_{10}N$
Amyl chinoline ...	...	...	...	...	...	$C_9H_7N \cdot C_5H_{11}$ or $C_{14}H_{18}N$

The iodides and sulphates of these substitution-bases were employed, and it was found that the iodides were slightly more active than the sulphates. The general action of methyl-chinoline resembled that of chinoline, but there was a distinct tendency to spasm, in this respect somewhat resembling the action of the higher members of the chinoline series. This was still more noticeable with ethyl-chinoline, and reached its maximum with amyl-chinoline, where, of course, the molecular weight was still greater. The characteristic action of chinoline was, however, always manifest. There was thus a contrast with the action of the higher bases of chinoline series, which do not produce complete unconsciousness. The substitution-derivatives of chinoline do produce unconsciousness, but along with it there are twitchings, muscular tremors, and even opisthotonos, indicating irritation of motor centres. Thus, although in the chinoline series, lepidine, dispoline, and isoline have the same empirical formula as methyl-, ethyl-, and amyl-chinoline, they have a different kind of physiological action.

## IX.—ACTION OF THE ADDITION-DERIVATIVES OF PYRIDINE.

Pyridine itself produces only slight excitement, and, except in very large doses, it is not lethal. Methyl-pyridine,  $C_5H_5N \cdot CH_3$ , or  $C_6H_7N$ , was found to have effects somewhat resembling those of picoline, but less marked. Three grains of pyridine-methyl-iodide given to a rabbit of two pounds weight caused nervous and vascular excitement succeeded by drowsiness. Comparative experiments were also made with the hydro-chloride of dipyridine,  $C_{10}H_{10}N_2 \cdot 2HCl$ , with the methyl-chloride of dipyridine  $C_{10}H_{10}N_2 \cdot 2CH_3Cl$ , and the latter was found to be the much more active of the two. Thus, a dose of one grain per pound weight of the hydro-chloride of dipyridine caused prostration, rapid breathing, partial paralysis of the fore-limbs, hyperæsthesia, and slight twitchings; whereas the same dose of the methyl-chloride of dipyridine was followed by severe convulsions three minutes after the dose was administered, and the animal died in five minutes. Ethyl-dipyridine was not examined.

## X.—ACTION OF THE ADDITION-DERIVATIVES OF PICOLINE.

The iodides of methyl-, ethyl-, amyl-, and allyl-picoline were prepared by Dr. Ramsay, and their physiological action was examined, with the following general results. 1. In all the action was much the same as that of a large dose of picoline, with the exception that there were tremors and a tendency to convulsions, and there was less stupor; in fact, it bore a resemblance to the action of dipicoline. Thus, the modification of physiological action was somewhat similar to what was observed with the analogous substitution-compounds of the chinoline series. 2. In ascending from the lower to the higher compounds, it was noticed that a smaller and smaller dose was required to produce marked symptoms. For example, a dose of one grain per pound weight of the methyl-iodide of picoline produced tremors, slight twitchings, and prostration, but the animal recovered; whereas the same dose of the allyl-iodide of picoline, after producing symptoms of a similar kind, but more severe, invariably killed the animal. The corresponding bromine-compounds were also examined, but their action differed in no respect from that of the iodine-compounds just described.

On three occasions, the following comparative experiment was made, the results of which may be clearly shown in a tabular form. Five rabbits were taken, of as nearly as possible two pounds weight:

Name of Substance.	Formula.	Dose in Grains.	Result.
A. Hydriodide of picoline	$C_6H_7N \cdot HI$	6	Excitement; stupor; prostration; recovery.
B. Hydriodide of dipicoline	$C_{12}H_{14}N \cdot 2HI$	2	Excitement; difficulty of respirations; twitchings; convulsions; death.
C. Methyl-iodide of picoline	$C_6H_7N \cdot CH_3I$	2½	Excitement; stupor; twitchings; recovery.
D. Ethyl-iodide of picoline	$C_6H_7N \cdot C_2H_5I$	1½	Excitement; twitchings; convulsions; death.
E. Allyl-iodide of picoline	$C_6H_7N \cdot C_3H_5I$	1	Excitement; twitchings; rapid occurrence of difficulty of breathing; Convulsions; death.

Death in all of these instances, except in A and C, was apparently the result of asphyxia from interference with respiratory centres, but the asphyxiated condition was most marked in the cases of ethyl- and allyl-picoline. Methyl-picoline resembled picoline in its action, except that twitchings and muscular tremors made their appearance. Doses of iodine and bromine, as iodide and bromide of potassium, and containing a quantity of iodine and bromine proportionate to that given along with the methyl-, ethyl-, and allyl-picoline, were subcutaneously injected without any noticeable effect. The potency of the addition-derivatives was, therefore, evidently due to the compound itself.

One cannot help being surprised at the activity of such a substance as picoline when introduced into the blood. Dr. Ramsay (*ut supra*) says: "I give an account of some attempts made to decompose picoline, all of which, with one exception, led to negative results. Picoline is not decomposed by potash in any form. Its vapour may be passed over fused caustic potash, or it may be boiled for a month with alcoholic potash, or it may be heated for some days to  $350^\circ$  with alcoholic potash, without undergoing the slightest decomposition. . . . It is not decomposed by a cherry-red heat, even in presence of lead peroxide or of lime. It may be distilled through a red-hot gun-barrel ten or twelve times without any deposition of carbon, and the picoline which distils over has not even a yellow colour. It is not attacked at the temperature of boiling sulphuric acid, nor by a mixture of strong nitric acid and sulphuric acid." He then shows that when picoline nitrate is heated to about  $200^\circ$ , a violent decomposition ensues. And yet, when a small quantity of a salt of picoline, or a salt of its substitution-derivatives, is introduced into the blood of a living animal, it will manifest its presence by unequivocal symptoms in the course of a few minutes. We are still ignorant of the physiological *modus operandi* of these substances.

XI.—ACTION OF DICARBOPYRIDENIC ACID,  $C_7H_5NO_4$ .

The action of the salts formed by this acid in union with sodium, ammonium, and methyl was examined, and they were all found to have an intense physiological effect, unlike that of any of the other compounds which have formed the subject of the present inquiry. The least active was the sodium-salt, and the most active was the compound with methyl—the

ammonium-salt occupying an intermediate position. The methyl-ether has a peculiar "mousy" odour, reminding one of conine. The general phenomena were as follow. When half a grain of the dicarbopyridenate of ammonium, in fifteen drops of water, was introduced under the skin of a rabbit of two pounds weight, the animal at once became violently agitated. It ran backwards and forwards on the table screaming loudly. Tremors of the whole body followed; the head drooped on the table; the fore-paws were at first weak, and then performed jerking movements, which rapidly terminated in strong tonic spasms of the anterior limbs alone; these spasms passed off, and the animal was quiet for a few moments and in a natural condition; during this period of quiet, the blood-vessels of the ears and the pupil rapidly dilated and contracted; the respirations were quick and shallow; another violent convulsion of a general character came on, and death occurred within four minutes of the administration of the dose. So far as could be observed, the animal was not unconscious. The character of the convulsions it is very difficult to describe. They somewhat resembled those of strychnine; but, as I have said, they were at first local, affecting only the fore-limbs. It was evident that reflex excitability was increased, as in several instances touching the animal caused a convulsive seizure. The action of the salt was thus unlike that of any of the chinoline and pyridine compounds, in none of which has any increase of reflex excitability been observed. We propose still further investigating the action of dicarbopyridenic acid, and also the action of leucolinic acid, the analogous acid of the chinoline series. It is sufficient, in the meantime, to note the sudden, rapid, violent, and fatal action of this substance on rabbits.

## XII.—GENERAL CONCLUSIONS.

1. There is a marked gradation in the extent of physiological action of the members of the pyridine series of bases, but it remains of the same kind. The lethal dose, however, becomes reduced as we rise from the lower to the higher.
  2. The higher members of the pyridine series resemble, in physiological action, the lower members of the chinoline series, except (1) that the former are more liable to cause death by asphyxia, and (2) that the lethal dose of the pyridines is less than one-half that of the chinolines.
  3. In proceeding from the lower to the higher members of the chinoline series, the physiological action changes in character, inasmuch as the lower members appear to act chiefly on the sensory centres of the encephalon and the reflex centres of the spinal cord, destroying the power of voluntary or reflex movement; while the higher act less on these centres, and chiefly on the motor centres, first as irritants, causing violent convulsions, and afterwards producing complete paralysis. At the same time, while the reflex activity of the centres in the spinal cord appears to be so far inactive as not to be excited by pinching or pricking, it may be readily roused to action by strychnine. These conclusions apply specially to rabbits; in animals of higher cerebral development, such as dogs, monkeys, and man, nausea and vomiting are produced in addition.
  4. On comparing the action of such bases as  $C_9H_7N$  (chinoline) with  $C_9H_{13}N$  (parvoline), or  $C_8H_{11}N$  (collidine) with  $C_8H_{15}N$  (conia from hemlock), or  $C_{10}H_{10}N_2$  (dipyridine) with  $C_{10}H_{14}N_2$  (nicotine from tobacco), it is to be observed that, apart from differences in chemical structure, the physiological activity of the substance is greater in those bases containing the larger amount of hydrogen.
  5. Those artificial bases which approximately approach the percentage composition of natural bases are much weaker physiologically, so far as can be estimated by amount of dose, than the natural bases; but the kind of action is the same in both cases.
  6. When the bases of the pyridine series are doubled by condensation, producing polymeric compounds such as dipyridine, dipicoline, etc., they not only become more active physiologically, but the action differs in kind from that of the simple bases, and resembles the action of natural bases or alkaloids having an approximately similar chemical composition.
  7. All the substances examined in this research are remarkable for not possessing any specific paralytic action on the heart likely to cause syncope; but they destroy life, in lethal doses, either by exhaustive convulsions or by gradual paralysis of the centres of respiration, thus causing asphyxia.
  8. There is no immediate action on the sympathetic system of nerves, although there is probably a secondary action, because after large doses the vaso-motor centre, in common with other centres, becomes involved.
  9. There is no appreciable difference between the physiological action of the bases obtained from cinchona and those derived from tar.
  10. The union of methyl, ethyl, amyl, and allyl with chinoline did not entirely change its characteristic mode of action, but their presence caused, along with stupor, a tendency to spasm and convulsion. Also, in the case of the pyridine and picoline addition-compounds, increase in molecular complexity and weight, while it does not entirely change the mode of action of the simpler compound, is always attended by a tendency to spasm and convulsion, probably arising from irritation of cerebral motor centres.
  11. The nature of the acid with which these compounds were combined did not appear materially to affect the physiological action, which apparently depended on the nature of the base. As a rule, bromides and iodides were more potent than chlorides or sulphates. No difference of effect could be observed between the iodine and bromine compounds of the addition-derivatives.
  12. Dicarbopyridenic acid ( $C_7H_4NO_2$ ), the only substance containing oxygen we have examined, is remarkable for rapidity and potency of physiological action; it also acts rapidly on the vaso-motor centres. In containing oxygen, it has a nearer resemblance in percentage composition to several alkaloids than any of the chinoline or pyridine compounds.
  13. Substances having the same percentage chemical composition, but a different chemical structure, may have different physiological effects. Contrast lepidine with methyl-chinoline, dispoline with ethyl-chinoline, isoline with amyl-chinoline, and quinine with cinchonine.
  14. Substances which have an action on the cerebral portion of the nervous system will act on animals differently, according to the degree of their cerebral development. Thus, chinoline causes in the dog, cat, and monkey, excitement and nausea and vomiting antecedent to stupor and anaesthesia; while in the rabbit none of these phenomena occur.
- It is understood that several of these conclusions are merely tentative, and may require to be modified on further investigation.

## CLINICAL LECTURE ON MYXŒDEMA.

BY WILLIAM ORD, M.D., F.R.C.P.,  
Physician to and Lecturer on Medicine at St. Thomas's Hospital.

GENTLEMEN,—By the kindness of two of my colleagues, Dr. Harley and Dr. Greenfield, I am able to show you two excellent specimens of the condition which I have ventured to call myxœdema. The two cases were severally recognised in the out-patient department by my colleagues, and were sent to Alice Ward for observation.

Your attention may first be directed to the general appearance. Both patients are adult women; both have swollen features and hands; in both the skin over the whole body is swollen and singularly dry and harsh to the touch, having very much the condition produced by washing in strong alkaline solutions. On the face the skin is semi-transparent, the eyelids and lips showing this particularly well. But neither on the face nor on the limbs does the skin pit on pressure. The hanging folds of the eyelids do not even yield to a firm pinch. In both women you will notice an even and persistent blush on the cheek, terminating by a sharp border at the lower border of the orbit, and standing in singular contrast with the bloodless eyelids which surround the eyes with two white circular areas. The hands in both are much swollen. But, on comparing the cases, you will see that, in one, having a yellowish tint of skin, and who is much weaker than the other, the hands are much more swollen, the fingers shapeless, and the skin like dry leather. This patient, I may observe, shows the appearances described by Sir William Gull, in his account of a "cretinoid condition supervening in women in adult life"; and you will agree that the term "spade-like", used by Sir William Gull, is well applied to the hands before you.

Both patients have a placid expression, to which the thick expressionless lips much contribute. In fact, face and hands are both wanting in the expression which comes of active answering of sensations to impressions from without. When the patients speak, you will be struck by the slowness of their articulation and the monotony of the voice. Both speak nasally, with frequent interruption by the act of swallowing, and with little explosive sounds produced in the posterior nares, in these respects resembling persons suffering from tonsillitis. And, if you look into the mouth and throat, you will see that the soft palate, tongue, and cheeks are all swollen and œdematous. Besides speaking slowly, the patients will tell you that they can act only slowly; that all action requires a considerable initial effort, and is carried on slowly; so that they take twice as long, or even more, than formerly in completing the ordinary actions of life; for example, in dressing. They both walk in a tottering way, with a tremulous balancing at each step, as though the flexor and extensor muscles could not act in perfect harmony, and as if pendulum-like vibrations were set going by the efforts at adjustment. Both are subject to sudden falls when walking, caused, as an analysis of the accidents shows, by such a want of harmony going to an extreme, the flexors ceasing to act before the extensors have begun, and letting the body fall between the two. Although the co-ordination here is bad in respect of time-adjustment, there is no paralysis; and, although there is want of tone, there is no wasting of the muscles. In fact, both patients are well nourished. And, although the mental actions are slow, they are well performed. The patients can write well, have fairly good memories, and are painfully aware of their slowness. Sensation is everywhere perfect, but response always slow. In both, the urine is of average quantity, varying between two and three pints daily; is of average specific gravity, and contains no albumen or sugar. In both, the viscera generally give healthy indications, with the exception that the arteries are somewhat tense and hard, and that the second sound of the heart is in both accentuated over the aortic valves. The temperature in both is below the average by about a degree of Fahrenheit's scale. Both are married and have borne children. The condition which you are investigating was not observed in either till after the age of 20. Here is a photograph of one at the age of 16, showing a very different appearance. No portrait of the other exists. Both have been suffering from the swelling for between three and four years.

These two cases agree in all respects with the cases upon which I have founded the new term "myxœdema" and with the cases described by Sir William Gull as "cretinoid". The term "myxœdema" is used as an expression of the physical condition which I believe to be the true cause of the symptoms, and denotes the basis of the appearances to which the term "cretinoid" is perfectly fitted.

At first glance, the patients have the look of persons suffering from acute Bright's disease. For a long time, such cases were classed in my mind as rather singular cases of dropsy without albuminuria; and the occurrence of general anasarca without albuminuria is noted in treatises on diseases of the kidneys. But there are many circumstances which help to show that the cases before you, and others like them, are not primarily dependent upon renal disease, being, on the other hand, dependent upon states of the skin.

1. In these and other cases, there has existed, besides the doughy not-pitting œdema, a marked dryness and harshness of the skin. The chest of these patients is as rough as emery-paper, and as dry. There is no secretion of fat or moisture. There is perfect sensation, but slow recognition of impulses.

2. The movements of the limbs are slow, and there is a tottering, due to want of perfect harmony in the co-ordination of muscular actions as regards any moment of time.

3. The speech is slow in beginning, the articulation slow to painfulness, and the voice "leathery" in its intonation.

4. The thoughts are slow; the movements of the will slow; the momentum of thought considerable; the mental processes are ultimately well performed.

All these are symptoms such as would result from conditions interfering with the ready reception of peripheral impressions. Now, in one case, I had last year the opportunity of making full examination of the tissues after death, in addition to a partial examination during life. And the most important point noticed was a general tumefaction of the connective tissue in all parts of the body; the fibrille being particularly well defined, owing to the infiltration between them of a gelatinous substance; their number being greatly increased, and the nuclei of the tissue more abundant than usual. This infiltration appeared to me to be an overgrowth of the natural mucin-yielding cementing structure, and the resulting textures reminded me strongly of certain embryonic textures, in particular of that of the umbilical cord. As a test of this, I submitted parts myself, and afterwards asked Dr. Charles to submit skin on a large scale, to chemical examination. The result was that, while, in ordinary skin and connective tissue, and in the skin of anasarca patients, there was a barely weighable proportion of mucin, the skin of the myxœdematous case yielded several hundred times as much—this very weighable quantity here exhibited.

In the skin, this sort of material was found forming a pad round and in the touch-corpuscles. Now, suppose every nerve-end of the periphery thus padded, and bear in mind, at the same time, the effect produced by lightly padding the external auditory meatus with cotton-wool. You lose volume, at all events, in respect of impressions, and lose also acuteness, and acquire slowness in the reception of them. Consider what this means when the periphery is largely or entirely involved: how, first, the relation of the body to impressions from without must be changed. Remember what an effect upon the central nervous system a widely extended surface-lesion of the most superficial kind may produce: the fatal effect of a scald:—similarly of surface-impressions, the bracing influence of dry keen atmosphere; the depressing influence of a damp close one; the various effects of baths. In close observation of the sick, you will always see that a persistent failure of the action of the skin is attended with nerve-symptoms having the character of depression. These are often supposed to be due to retention of poisons which ought to be eliminated by the skin. There is better reason, however, to attribute them to the alteration of peripheral nerves, of which the want of action is a result. I have seen more than one case in which torpor and a slow perception were associated with a permanent dryness and harshness of skin, where, on the use of a hot-air bath or other means of inducing perspiration, the symptoms passed away at once, to return at once on the passing off of the perspiration. The want of action in these cases may be due either to compression of glands or to failure of the reflex actions upon which secretion depends. The microscope shows the glands to be greatly attenuated and encroached upon; but disease may well account for this. We may compare the effects of varnishing the skin in animals. Valentin and Edenhuizen have shown that the coating of the skin of rabbits with impermeable varnish is followed by rapid loss of temperature, by remarkable slowness of respiration and by speedy death, the fatal effect following when no more than one-sixth of the entire surface is thus treated. And, though Senator has treated men similarly without producing the same effects, the analogy holds good for our purpose.

If a temporary failure of normal peripheral stimulation be sufficient to produce torpor, the long-continued influence of even a slight failure may be expected to be followed by an increasing torpor of the centres, just as a paralysed limb wastes for want of exercise. And so one would expect the slowness in voluntary movements and the slowness in thought to follow the first sense of mere heaviness or sluggishness. In more advanced cases than these before you, the increase of lethargy becomes most distressing. The day is spent in overtaking the duties which ought to have been over in the first hour of it. The muscular errors become so marked that frequent falls occur. One lady under my observation broke both ligamenta patellæ in succession, owing to the wide separation of the action of flexors and extensors, the latter contracting, during a fall produced by this want of punctuality, just in time to cause the fracture. The same patient habitually walked in a singular tottering way, quivering from head to foot as each step was taken. Her head hung on her chest, in consequence of the incapacity of the will to maintain muscular action, and the thick blubber lips, swollen eyelids, and dribbling saliva completed a very cretin-like picture indeed.

In relation to muscular movements, any padding of muscular nerves would be likely to cause slowness of transmission of impressions of contractions, and so make the first step in the failure of co-ordination.

The two cases which I have followed to a fatal termination, the one after eight years, the other after five years of observation, both ended by way of renal disease. In one, a *post mortem* examination was made, as already noted. The kidneys here shared the condition of the skin. There was enormous interstitial growth of connective tissue of this soft gelatinous kind by which the secretory tissue was compressed and the early stage of granular kidney in part imitated. The same invasion had occurred in other organs, notably in the liver and heart; but I could not satisfy myself of the existence of the same or any parallel condition in the central organs of the nervous system. Specimens of skin from various parts, of kidneys, liver, heart, brain, and cord, are here under the microscope.

Reviewing the cases which have been under my notice, I may state that all were women of adult age; some married, some not. Of the married, some had children even after the dropsical condition had been well developed; there was not any known taint of syphilis in any, nor any general history of excess in food or stimulants. All shared the state of skin and the characteristic face, the absence of albuminuria, the slowness of perception, thought, and action, particularly of speech. In all the affection was general and progressive. There are a few maladies from which it may be necessary to distinguish this:

1. *From Bright's Disease.*—The variety of states included under this head is very great, and it is true that the fatal termination in the two cases followed to an end was by uræmia. But, unless the definition of Bright's disease is very much extended, it is hard to include under it cases in which, with a mucin-yielding gelatinous dropsy, a complete absence of albuminuria is observed during many years; to say nothing of the nervous symptoms so definite in their character.

2. *From Sclerema and Allied Conditions.*—In these, the skin is hard instead of soft; the affection is a local one; there is a tendency to healing at one point and extension to another: three points which completely separate the two affections.

3. *Cretinism.*—In relation to this, I now cite a point to which I have not previously directed your attention. Examining the throat and neck of both cases, you will find little or no trace of a thyroid body and a decided resilient fulness on both sides of the neck above the clavicles. These are conditions that have been noted in two cases of idiocy by Mr. Curling, and in a series of cases of cretinoid idiocy by Dr. Fagge. In Mr. Curling's cases, there was complete absence of the thyroid, and the supraclavicular masses were composed of fat—of adipose tissue.

In the fatal case examined by me, the thyroid was reduced to about a fourth of its natural size, and, being flattened against the larynx, was hardly felt during life. Its normal structure was almost entirely wanting, being replaced by myxœdematous infiltration. The absence of a thyroid gland in cases of cretinoid idiocy is certainly curious, goitre being very abundant in regions where cretinism is endemic. But, in these regions, the concurrence of goitre with cretinism is not the rule, only about one-third of the crétins having goitre. In fact, Dr. Fagge argues that goitre is a protection against cretinism, and supports his argument by citing these cretinoid cases in which the thyroid is deficient.

In comparing these cases with cases of cretinism, it must be observed that many crétins are oedematous, often from birth; and that cretinism is a condition which gradually develops after birth. In many cases, it is difficult to decide whether a child born under suspicious circumstances is going to be a crétin, and children born apparently healthy

do not become crétins after four or five years of age. Now, as the appearance of a decided crétin is absolutely characteristic, it follows that the change is a gradual and acquired one. Supposing a child to be born with a myxœdema, cutting it off from the first day of life from the external influences by which the education of its senses and sentient nerves should be effected, it is also cut off from the stimulations by which the central nervous system is kept in exercise and made to nourish itself. In proportion as the padding of nerves is effective, the child is reduced to the condition of a tunicate animal; reverts, in fact, to the condition of its far distant ancestor, and remains a bag of viscera with ill-developed brain, with misshapen limbs and unformed skull;—in the complete outcome of cretinism an organic being certainly, but not a human being.

The *post mortem* examinations of crétins demonstrate the existence of great imperfection in the development of the brain, and correlated imperfection in the development of the skull, particularly of the base of the skull; the growth and shaping of the bones being dependent on, and proportional to, the growth and shaping of the contained organs. The skin of crétins is hard, thick, and leathery; their movements are slow, their gait tottering, and their limbs small and feeble. These are all things which would agree with an hypothesis that cretinism began as a simple general myxœdema; and I hope some day or other to investigate this subject further in the regions where cretinism is endemic.

The sketch now put before you will be enough, in conjunction with the cases upon which the remarks are founded, to prove to you, first, that there exists a substantive affection in which a gelatinous dropsy without albuminuria is associated with a cession of the normal cutaneous secretion and with certain well marked nerve-symptoms of a bradæsthetic kind; second, that the various symptoms may be explained by the existence of the gelatinous dropsy; third, that this gelatinous dropsy consists in an excessive formation of the elements of connective tissue, particularly of the mucin-yielding or cementing element; the state here acquired resembling an embryonic state to which it may be a reversion or degeneration. This idea of reversion or degeneration is indeed, I am inclined to think, the ultimate explanation of the whole process.

If you have followed me carefully in the short analytical exposition of the relation between central nervous system and periphery, you will have had your attention drawn to the fact that the centre is very dependent on the periphery, particularly as respects its nutrition, which is determined by the due exercise of its function of reception and response. We are accustomed to see the centre in the position of control. We must also be accustomed to see the periphery in control, conditioning by regularly ordered stimulation the very existence of central power. To this influence of the periphery you will learn, as your experience grows, to give an increasing attention; and, if no other lesson be learned to-day, this one at least is of great practical value.

## OBSTETRIC MEMORANDA.

### CASE OF COMPLETE INVERSION OF THE UTERUS SUCCESSFULLY REDUCED.

THE case, to which I was called, occurred in the practice of a friend. Mrs. T. was confined of her ninth child on March 11th, 1878. The labour was not a rapid one, but normal in every respect to the completion of the second stage. No unusual traction was made on the cord, I am assured, when suddenly the placenta, which was adherent to the uterus, was expelled, together with the inverted uterus, beyond the vagina. The adherent placenta was at once separated, and the uterus returned into the vagina. Seeing the gravity of the case, and wishing to share the responsibility with another, my friend sent to ask my assistance. I found the inverted uterus lying in the vagina, with its spongy-like surface, from which there was considerable oozing of blood. On a first attempt at reduction, the uterus proved unyielding. I then grasped the tumour at its superior extremity, gently compressing it, when it relaxed a little. A steady upward pressure on the fundus with the back of the hand and knuckles in a few moments effected reduction, the organ suddenly leaving the hand, as Churchill describes it, "like a bottle of India-rubber when turned inside out". On placing the hand on the abdomen, the restored uterus could now be felt in its natural position above the pubes, and well contracted. The comparative facility by which reduction took place was no doubt owing to the immediate diagnosis and prompt treatment of the case, not more than half an hour elapsing between the inversion and the replacement. The patient had no untoward symptoms, and made a good recovery.

G. M. BRUMWELL, M.D., Mossley.

# REMARKS ON THE TREATMENT OF WOUNDS.

By GEORGE W. CALLENDER, F.R.S.,  
Surgeon to St. Bartholomew's Hospital.

IN a recent number of the *Nineteenth Century*, Professor Tyndall has stated that the system of wound-treatment which I employ and that of Mr. Lister are practically the same.

From time to time, I have stated the results obtained with the cases under my own observation; and as these results continue their satisfactory character, it is unnecessary to refer to them further. It may, however, be of interest if it be mentioned that, tabulating the cases treated in the two wards which are under my care (one for male, and the other for female patients), there have been under treatment during the last eight years 2,070 cases, with 68 deaths; showing a mortality of about 34 per 1,000, or of 3.4 per 100.

Amongst these cases are included the chief operations which have been, of necessity, performed. I say, of necessity, because I trust that each year we are learning how better to avoid the need for having recourse to many an operation by closer attention to details of treatment, more especially in the case of severe lacerated and other wounds. Not that the total number of operations is thus materially affected, for, with improved methods for the treatment of wounds, operations are now indicated which, until recently, were rarely if ever practised.

The death-list is largely made up of patients dying from burns, from diabetes, albuminuria, phthisis, caries of the spine, spina bifida, hernia, and such various troubles as, unfortunately, are still prominent in such a list.

Granting, with Professor Tyndall, that the method we adopt is akin practically to that used elsewhere, I wish more particularly to point out, as I have before stated more than once, that it is essentially one of extreme simplicity, one which can be effectually carried out by any surgeon under any circumstances without any difficulty.

In illustration, the case of a patient aged 16 may be referred to. For the treatment of a severe case of genu valgum, I opened the knee-joint, and with a saw separated the internal condyle of the femur from the shaft of the bone. The condyle being displaced upwards, the limb was easily brought into the straight position, and in that position was secured by a long splint (Dr. Ogston's operation). The wound, which admitted at one and the same time the long knife used for penetrating and dividing the soft parts and a stout saw, had a depth of about three inches and, where the skin was divided, a length of about one inch. No carbolic or other spray was used at the time of the operation or at any time subsequently. The wound was covered with a doubly folded piece of lint soaked in carbolised oil (1 in 12); over this was placed a larger piece of lint, likewise soaked in the oil; and over all a yet larger surface was covered with some ordinary gutta-percha tissue. The dressings were examined daily, the gutta-percha tissue being lifted and the outer layer of lint being changed, the gutta-percha being then replaced. The inner layer of lint was left undisturbed on the wound for three or four days, being each day refreshed with carbolised oil (poured upon it or painted over it with a camel-hair brush). Whenever this layer of lint was changed, the wound was freely exposed to the air. The patient got well without any constitutional disturbance, and the parts healed in the ordinary course. Treated in a similar manner, there are at this time under observation in one of my wards a severe compound fracture of the femur into the knee-joint, and two cases of compound fracture of the leg; in one of the latter, it was not necessary to disturb the inner layer of lint for nine days after its first application.

Of course, these are but casual illustrations, from many similar cases, to show how a very simple plan suffices to ensure that condition of cleanliness which is essential to the sure and rapid healing of severe wounds, or wounds practised upon parts which it was formerly considered hazardous to involve in operations. With this cleanliness must go "rest", and with this will be ensured "ease"; and when deep wounds, or wounds the surfaces of which are not easily and closely adapted, are concerned, thorough drainage is of prime importance.

I do not like to write of "antiseptic" treatment, because I regard the treatment of wounds as a matter of strict adherence to the established rules of surgery, and I consider it undesirable to prefix a term

which may seem to specialise the method of wound-management. But the results claimed for antiseptic surgery can be ensured by the plan which we have now used for many years, and of which I venture to write as being as simple as it is efficacious.

I believe, with the exercise of care and by close attention on the part of the surgeon, that different methods of treatment will yield good results. As to the plan employed in my wards in relation to the proposition that germs are causative in producing bad results in the case of operation and other wounds (but without committing myself to this view of their influence), let me add that, whilst other methods aim, amongst other things, at the entire exclusion of such germs from wounds, I shall rest content to allow their ingress, feeling quite sure that after such entry they are absolutely prevented from doing any harm by the treatment we adopt.

Being not infrequently asked for information respecting the general results of amputation operations at St. Bartholomew's Hospital, I take this opportunity for adding tables compiled from the statistical reports of the hospital, showing all the amputations performed during the undermentioned periods in continuation of the cases previously tabulated from 1853 to 1863, both years included (*Medico-Chirurgical Transactions*, 1864).

## SCARLATINOID ERUPTION IN THE AGUE OF YOUNG CHILDREN.

I AM much obliged to Dr. Handfield Jones for pointing out that he had already noted the occurrence of cutaneous hyperæmia and red eruption in the malarial affections of young children, and regret that I had not been cognisant of this when I published my paper on this subject a fortnight ago. It is satisfactory to find that my experience corroborates his previous observations. The chief difference is, that in the first of my cases the rash appears to have been brighter and more like that of scarlatina, and the malarial fever a genuine tertian ague, instead of the less regular intermittent described by Dr. Handfield Jones. I can further confirm his statement, that cases of malarial disease arise in London. I have seen several instances in children who have never been away from the city.

W. B. CHADLE, M.D., F.R.C.P.

## OBSERVATIONS

ON THE

SUCCESSFUL REMOVAL OF A SOLID UTERINE  
FIBROMA WEIGHING SEVENTY POUNDS.By T. SPENCER WELLS, F.R.C.S.,  
Consulting Surgeon to the Samaritan Hospital.

ON February 4th, 1878, in consultation with Mr. Symonds of Oxford, I saw a single lady, thirty-six years of age. Her abdomen was enormously enlarged by a solid tumour, which extended upwards behind the lower ribs on both sides, pressing them outwards, and passed downwards into the pelvis, filling up the hollow of the sacrum, and causing prolapse of the posterior wall of the vagina. This sketch, al-

though made of another patient, gives an excellent idea of the appearance of the lady, except that it hardly shows how much the tumour encroached on the thorax, and there was considerable cedema of the feet and legs, which was said to disappear for a time after the cessation of each monthly period.

The cervix uteri could not be reached, and it was impossible to ascertain where the uterus was situated. The catamenia were regular in time and normal in quantity. Mr. Symonds had advised removal of the tumour in 1876, when it was much smaller; but the patient and her friends steadily objected. The first symptom of illness was in 1868, when backache became troublesome; and, early in 1869, Mr. Barker of Wisbech found a small hard swelling in the left side of the abdomen. This gradually enlarged; and Mr. Barker informs me that in June 1871, "in consultation with Dr. Protheroe Smith, the question of removing the tumour was canvassed, and it was then decided by us that, taking into account the low vital power of the patient and the fact that several forms of struma had shown themselves in several members of the family, it was decided that operative measures were not justifiable". After this consultation, increase went on, at first slowly, but much more rapidly during the year 1877.

As the tumour was quite solid, not fluctuating anywhere, and as the uterus could not be found, I expressed my opinion to Mr. Symonds that an accurate diagnosis was impossible; that I thought the tumour more likely to be uterine than ovarian; but that it might be some such rare form of abdominal fibroma as I had once removed in Germany, and which had been described by Virchow as *fibroma molluscum*, not necessarily connected with either uterus or ovaries. I also said that only an exploratory incision could determine if the tumour could be removed or not; and, that if the attempt were made, it should rather be at the wish of the patient than by the advice of the surgeon. At first, she decided against operation; but suffering became daily greater, and it was arranged that I should make an exploratory incision on March 7th, four days after the cessation of the catamenia. Accordingly, on that day, chloro-methyl being administered by Dr. Day, and Dr. Bantock, Mr. Thornton, and Dr. W. Webb assisting me, Mr. Symonds and Mr. Hill also being present, I made an incision in the median line between the umbilicus and pubes and cut into the substance of a solid fibroid tumour, which was closely adherent to the abdominal wall. After separating some adhesions, I passed my hand into the peritoneal cavity, and found the tumour to be free from adhesions on the left side, also behind and above, but to be closely bound down on the right side. In front, the bladder was so high that the incision could not be carried within about four to five inches of the pubes, so it was extended upwards about five or six inches above the umbilicus, as soon as I had convinced myself that it would be possible to remove the tumour. A

large piece of adhering omentum was detached from the upper part and behind. Towards the left side, a broad mesenteric attachment was divided by the knife, large blood-vessels being temporarily secured by torsion-forceps. I was then able to shell the tumour out from a sort of vascular capsule formed by the two layers of the right broad ligament, and separate it, but only by the knife, from the posterior surface of a uterus of normal size, after forcibly pulling the tumour up out of the pelvis and separating it from the rectum, to which it adhered closely. The right ovary (although normal) was cut away, because the Fallopian tube had been divided and the broad ligament was much torn. The left ovary and Fallopian tube were not disturbed. Several silk ligatures were applied to the right of the uterus, and also to open vessels on its posterior surface when the tumour had been cut away. Two large pieces of omentum were cut off, after securing them by ligature. I then found that the two opposite sides of the remnant of the capsule of broad ligament (out of which I had enucleated the tumour) could be brought together behind the uterus, so as to complete the union of the divided peritoneum from the lower angle of the opening in the abdominal wall, the elevated bladder and the fundus uteri, all down the back of the uterus to the rectum. I did this by an uninterrupted suture of fine silk, making about twenty points of suture, and finishing close to the vagina and rectum. In this way, the peritoneal sac was completely shut off from the torn cellular tissue of the pelvis. A good deal of sponging was necessary to remove clots of blood from the peritoneal cavity; but very little blood was lost considering the great size of the tumour and the extent of its attachments. The opening in the abdominal wall was closed by twenty-five silk sutures. The patient was placed in bed exactly an hour from the minute when she began to inhale methylene. She was faint and very chilly, a spray of a solution of thymol (1 in 1,000 of water) having played upon the abdomen all through the operation; and, although sponges moistened by warm thymol solution protected the intestines and abdominal cavity to some extent, the chilling effect of the spray was manifest.

On examining the tumour, it was found that about two pounds of blood had drained from the vessels divided in its capsule and at its line of separation from the uterus. Its circumference in three different directions was 52 inches at the smallest, 57 inches at the largest, and 53 inches in a third. A small piece was cut out for microscopic examination, and the tumour was then weighed in the Museum of the Middlesex Hospital, and found to be 68 lbs. 6 oz. The tumour was "chiefly composed of cells with relatively large nuclei, many containing several nucleoli, of the type difficult to distinguish as distinctly muscular; but in some parts of the tumour unstriped muscle-cells were manifest" (J. K. Thornton).

I have very little to add as to the progress after operation, except that the temperature seldom rose above 99 deg., only reaching 101.2 deg. (the highest noted) once. Only four opiates were given. There was never any distension of the abdomen. Six days after operation, the bandage and dressing were removed for the first time. The four or five layers of thymol gauze next the skin were damp with serum; the outer layers were quite dry. The wound was united from top to bottom. All the twenty-five sutures were removed, and the line of union was almost imperceptible. The dressing was only changed twice after this; and, except a few drops of pus from one of the central stitch holes, union was perfect by first intention.

For a few days in the second and third week after operation, the patient occasionally vomited, and was weak and low-spirited, and there was a considerable swelling in the pelvis, as if from a hæmatocele in the front of the rectum, to such an extent that the uterus could not be felt. There were frequent, very offensive, watery motions, but never any purulent discharge. When the swelling in the pelvis began to subside, and after washing out the rectum with thymol solution, rapid amendment set in and went on. Two days before she left London by rail for Oxford, on April 8th, just a month after operation, I carefully examined the pelvis by vagina and rectum, and really could not find any trace of an operation having been performed. The uterus was in its normal position, was movable, and of ordinary size and weight. Mr. Symonds wrote that he was surprised to see her looking so well after the journey; and I received a letter, dated April 16th, saying that she was gaining her strength, could walk downstairs, and that her appetite was good. She wrote herself on May 4th, saying, "I am able to walk a little, and get out in the air as much as possible."

THE Local Government Board have intimated that they will forthwith issue a Provisional Order that so much of the Townships of Bollin-Fee, Fulshaw, and Pownall-Fee, Cheshire, as are not included in any Urban Sanitary District, shall be constituted a Local Government District.

# PATHOLOGICAL ILLUSTRATIONS OF THE LOCALISATION OF THE MOTOR FUNCTIONS OF THE BRAIN.\*

By RINGROSE ATKINS, M.A., M.D.,

Resident Medical Superintendent District Lunatic Asylum, Waterford; late Assistant Medical Officer District Lunatic Asylum, Cork; etc.

(Concluded from page 641 of last number.)

**CASE V.** *Adhesion of the Pia Mater to and Softening of the Middle Third of the Left Ascending Parietal Convolution, Portion of the Ascending Frontal, and Edges of the Gyrus Supramarginalis and Gyrus Angularis; Paralysis of the Right Hand and Arm.*—W. J., male, aged 38, was admitted into the Cork District Lunatic Asylum on December 3rd, 1876, suffering from general paralytic dementia. The patient, a Welshman, was a discharged soldier, and his illness, of eight months' duration, was attributed to a fright he received while serving as pointsman on the railway near Mallow, County Cork. It is needless for my present purpose that I should enter into the minute details of his history or condition; suffice it to say that he had the uncertain gait, the trembling muscles, the hesitating speech, the jerky movements of the tongue, and the unequal pupils (the left being the larger), physically characteristic of this fatal malady. Mentally, he was dull, stupid, and demented, with occasional vivid hallucinations of sight; but never developed any of the delirious conceptions or ideas of grandeur which mark this disease from the mental point of view. During his residence in the asylum, every function slowly but surely deteriorated; he became more and more helpless bodily, but without any distinct paralysis, and demented mentally; the power of speech and of protruding the tongue diminished, and the muscular tremblings and twitchings increased, while he lost all control over the bladder and rectum.

On April 29th, 1877, the following report was made. "Since March 13th, when the last note was recorded, the unfortunate man has been steadily growing worse, and is now a pitiable object to look at. Though kept out of bed in an arm-chair, he has become quite incapable of walking unsupported; he can, however, move the arms and legs freely. For the past two or three days, he appears to be unable to protrude the tongue, and has not spoken; when pressed to do so, he makes feeble efforts with the facial muscles, which twitch convulsively. The general muscular tremor has increased, the irregularity of the pupils still exists, but to a less degree than before; he is greatly emaciated, the muscular groups being apparently generally and equally wasted. He now takes his food readily when fed. Urine and feces are passed involuntarily. This morning, he was found to have become during the night quite unconscious. The attendant reports that he had no noticeable fit of any kind. He lies on his back with his eyelids closed, his eyes fixed, the conjunctivae being quite insensible to the touch of the finger. The pupils are equal in size, contracted and fixed. The arms are flexed across the chest, and, when raised, require some force to straighten them, the muscular groups being very rigid; the lower limbs are to a less extent in a similar condition. Tactile sensation appears dulled, no outward manifestation being made when the skin is sharply pricked with a pointed probe. Reflex excitability is increased, the feet moving convulsively when the soles are tickled. Respiration is unaffected."

April 30th.—The comatose condition had passed away; he was to-day brighter; had opened his eyes, and looked around him, appearing to partially recognise those about him, and was able to swallow liquid food. The pupils were larger, and the inequality was again observable, the left being of greater diameter than the right. The features were much sunken; there was a tendency to diarrhoea.

May 1st.—He was in much the same condition as yesterday; diarrhoea was less; there was decided loss of power in the right hand and arm. Bed-sores were commencing over the lower portion of the sacrum.

May 2nd.—He was somewhat more sunken than yesterday. The right hand and arm were to-day completely paralysed; when raised, the muscles were in a state of tonic rigidity; but, when let go, the hand and limb dropped powerless, and could not be moved by any voluntary effort. The back of the hand was swollen and puffy; the epidermis between the forefinger and thumb was raised into a large irregular-shaped bleb containing yellowish-brown serum, surrounded by an erythematous zone. The fingers were flexed and rigid, the nails pressing on the palm of the hand; they were straightened with difficulty, and, when released, returned at once to their former position.

On the posterior aspect of the second phalanges of the fore-middle and third fingers were elongated ovoid bullae of fluid, which had appeared since yesterday. The power of movement of the left hand and arm was but little affected; the grasp was still, comparatively speaking, strong; when he got anything into the hand, he clutched it so firmly that it was difficult to disengage it. The muscles of this limb were atrophied to a considerable extent, especially the interossei, the back of the hand forming a strong contrast to its swollen fellow. The man did not emit the slightest sound or noise of any kind. When the mouth was forcibly opened, the tongue could be seen moving about in the buccal cavity, the organ being atrophied, red, and glazed. Cutaneous sensibility seemed to be almost extinguished over the entire surface of the body. Reflex excitability was diminished, especially in the right leg. Farado-muscular contractility was weakened in the lower limbs, but persistent in the upper limbs, especially in the left arm and facial muscles. He lay on his back, with the legs drawn up and the pelvis rotated towards the left side. Across the junction of the sacrum and buttocks was a large eschar surrounded by an erythematous zone; and there was a commencing bed-sore midway on the left iliac crest.

May 4th.—For the past two days, the patient had been sinking, and he died this morning at 5.30 A.M.

May 5 h.—*Necropsy*, thirty hours after death. Rigor mortis was strongly marked. The body generally was much emaciated. Over the lower portion of the sacrum, and extending across the left half of the buttocks, was a black eschar of a quadrilateral shape, about five inches in length, surrounded by the remains of an erythematous zone. The surface of the abdomen was flattened and of a blue colour. The bulke above mentioned still existed on the fingers and hand. The scalp was thin, and considerable force had to be exercised to strip it from the bone. The cranial outline was asymmetrical, the right hemisphere being more prominent than the left, the fronto-parietal regions of the latter being flattened and sloping. The consistence of the bone under the saw was normal. The inner surface of the calvarium was of a slaty-blue colour. On the left frontal eminence was what appeared to be the remains of an old fracture, to which the scalp was firmly adherent. There was no corresponding mark on the inner surface. The outer surface of the dura mater over the vertex of the hemispheres appeared normal. Laterally over the left hemisphere, it was covered with a thin layer of clear gelatinous material readily scraped off with the scalpel. On cutting through the dura mater, between two and three ounces of non-sanguineous turbid sero-purulent fluid escaped; on raising the membrane, it was found adherent beneath at each side of the longitudinal cleft, and also connected over the hemispheres with the arachnoid by filiform bands; its inner surface covering the fronto-parietal convolutions of the left hemisphere was lined with a soft layer of yellow gelatinous material easily removable. The corresponding surface of the arachnoid was similarly coated, the coating extending anteriorly over the membrane covering the three tiers of frontal convolutions, and reaching posteriorly across the ascending frontal and parietal convolutions, as far as the edges of the sulci bounding the postero-parietal and portion of the inferior parietal lobules. The gelatinous deposit existed also over the upper tiers of the temporo-sphenoidal lobe, the occipital and annectent gyri being almost entirely free. The pia mater was, in the regions specified, thickened and opaque, especially that bridging the various sulci, where were scattered here and there numerous small spots of a greenish-yellow exudation. The Pacchionian bodies along the median cleft, where the dura mater had been attached, were shaggy, rough, and eroded. The membrane covering the convolutions of the right hemisphere was free from any of the gelatinous material: where it bridged the sulci, however, it was thickened and opaque, but to a less extent than at the left side. The fronto-parietal region of the left hemisphere was flattened, the individual convolutions appearing to be attenuated and angular. In removing the brain from the skull, about four ounces of sanguineous fluid escaped from its base and the upper portion of the spinal canal; the osseous configuration was normal; from the anterior and middle fissure of the left side, a thin layer of gelatinous material could be scraped. The arteries at the base of the brain were delicate-looking and nowhere atheromatous; the basal ganglia were normal, the crura cerebri being somewhat diminished in consistence to the touch. The entire brain, previous to draining, weighed 1555.209 grammes; the cerebellum, pons, and medulla 138.8 grammes. The hemispheres were carefully divided into equal halves; the left weighed 641.5 grammes, the right 684.2 grammes, giving a difference of 42.2 grammes in favour of the right hemisphere. The ventricles and central ganglia were normal in appearance. The left hemisphere was placed in nitric acid solution (one to five of water). After macerating for thirteen days, the pia mater was removed, the membrane separating readily, leaving the portions where it was adherent to the cortex distinctly localised and eroded with ex-

\* Read in the Section of Psychology at the Annual Meeting of the British Medical Association in Manchester, August 1877.

cavated and irregular margins. The portions thus affected were a small portion of the middle of the ascending frontal, the middle third of the ascending parietal convolution, extending farther below than above, the anterior edge of the gyrus supramarginalis, and a little piece of the gyrus angularis where it joined with the gyrus supramarginalis adjoining the ascending parietal. Not only was the membrane adherent to the cortex in these situations, but the latter was softened and pulpy, especially the portion of the ascending parietal, the tissue being broken down for a depth considerably greater than its own thickness and extending into the white matter subjacent. The pia mater was also adherent to the posterior portion of the superior frontal convolution on its inner aspect, and to small spots on the middle and posterior third of the inferior frontal, together with a few little patches on the posterior folds of the gyrus angularis. These adhesions were confined to the summits and sides of the gyri, the membrane stripping readily from the bottoms of the sulci; the latter were wide, especially that between the ascending parietal and gyrus supramarginalis.

The patches of softening and the adhesions are mapped on this diagram (fig. 3), the hemisphere of the brain preserved in the nitric acid

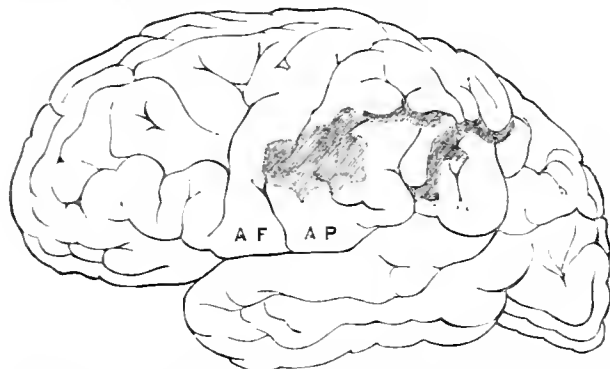

Fig. 3.—Adhesion of Pia Mater to, and Softening of the Middle Third of, the Left Ascending Parietal Convolution, Portion of Ascending Frontal, and Edges of the Gyrus Supramarginalis and Gyrus Angularis.

solution being also before you; the changes, owing to the shrunken condition of the tissue from the action of the acid, are not so well marked now as when seen in the fresh state: the organ, however, has been preserved from the action of the air, and has not, therefore, firmly hardened or changed colour.

Microscopical examination showed the surface of the pia mater to be covered with densely crowded free nuclei. The walls of the vessels were somewhat thickened and similarly overlaid with nuclei; in some instances, so closely packed that it was difficult to make out the boundaries of the coats of the vessels; where the latter were seen, the muscular coat was tolerably distinct, regular in outline, and unaffected. Scattered over the surface of the membrane and on the vessels were aggregations of clear circular disc-like bodies slightly or not at all tinted by carmine, forming clusters, rosettes, or irregular groups, varying in size from a minute dot to a disc as large again as a blood-corpuscle. These appear to me to be free fat or oil globules, the result of degenerative processes which have taken place. Teased preparations of the fresh brain-tissue stained with aniline blue black showed the larger pyramidal nerve-cells, in the great majority of instances, to be destitute of their basal processes, the angles being eroded or rounded, and the protoplasm loaded with granules, the nuclei being invariably present. Aggregations of globules quite similar to those observed in the pia mater were present here also, and, in several specimens from the apices of the ascending parietal and ascending frontal convolutions (right hemisphere), the so-called "giant-cells" at once arrested attention by their superior size and close resemblance to the multipolar bodies of the anterior cornua of the spinal cord. Prepared sections showed the vessels to be somewhat thickened and excessively nucleated, and surrounded by dilated perivascular spaces (?). The larger ganglion-cells were in different stages of pigmentary degeneration, and the neuroglia was coarse and molecular.

The importance in general paralysis of the localised adhesions of the pia mater, in the fronto-parietal regions, as a pathognomonic mark of the disease, has been lately discussed by Dr. Crichton Browne in the sixth volume of the *West Riding Asylum Reports*; and, more recently, the relations between the cortical lesions resulting therefrom and the various motor symptoms occurring in the course of this fatal malady, have been treated of at some length by Dr. Achille Foville in the

*Annales Médico-Psychologiques*. As the result of his observations, the latter concludes that, in general paralysis, the cortical lesions of the fronto-parietal convolutions are the direct cause of the motor troubles, and that on the localisation and intensity of these lesions depend the localisation and intensity of the various ataxic, spasmodic, and paralytic accidents which may occur. In the present instance, we have a paralysis confined to the right hand and arm, with spastic contraction of the muscles coming on towards the close of a case of the disease in question, the necropsy revealing localised cortical lesions resulting from adhesions of the pia mater occupying portions of the ascending frontal and ascending parietal convolutions, and of the inferior parietal lobule. Granting, then, that these localised cortical lesions and the partial paralysis stood to each other in the relation of cause and effect, which the absence of other lesions leaves no reason to doubt, we have here an interesting verification pathologically of the results obtained experimentally in this region. Ferrier, as is now well known from the phenomena produced both by electrical irritation and circumscribed destruction of the cerebral cortex in monkeys, localised the centres for the movements of the arm and hand in the ascending frontal and the ascending parietal convolutions, the regions which were here chiefly affected; and, although the localisation of the diseased patches is more circumscribed than that which produced similarly extensive symptoms experimentally in the monkey's brain, yet, from the nature of the pathological process causing the cortical lesions, it is more than probable that the irritation from the specially diseased foci spread to neighbouring centres in the same convolutions, thus leading to their involvement and the loss of voluntary motor power in the muscular groups they govern. The spastic contraction of the muscles, as an indication of irritation of the nerve-centres, would, I think, appear to favour this view.

The presence of the visual hallucinations with the disease in the angular gyrus, together with the fact that the prominent cerebral lesions were at the same side as the dilated pupil, and about the regions which have been found experimentally to govern its motility, are interesting points in this case. The rapid formation of the bullæ on the paralysed hand and the acute bed-sore are also noteworthy. It is to be remarked that the latter was primarily sacral, and the side of the buttock to which it subsequently extended was the opposite to that of the paralysed limb: a fact contrary to the statement of M. Charcot, that, when an acute bed-sore forms in cases of cerebral hemiplegia, it is invariably at the same side as the paralysed limbs. I may add here that the spinal cord presented no gross lesions; the histological alterations I shall detail elsewhere, as well as those in the medulla oblongata.

CASE VI. *Softening of the Lower Two-thirds of the Left Ascending Parietal Convolution; "Foyer" of similar Softening in the Central White Matter of the Hemisphere; Right Hemiplegia.*—For the history of this case, and for the opportunity of being present at the *post mortem* examination and subsequently investigating the condition of the organs, I am indebted to my friend Dr. Cremen, Physician to the Union Hospital, Cork.

M. R., female, aged 68, was admitted under Dr. Cremen's care on March 4<sup>th</sup>, 1877. The patient, a fish-vendor, had always been a hard-working woman of tolerably temperate habits, and, up to three years since, had been in the enjoyment of general good health. About that time past, she began to feel oppressed after exertion, and experienced a sensation of giddiness, noises in the head, and failure of memory. These symptoms gradually increased, and finally she had to seek admission to hospital, when she presented the following appearance and symptoms. The skin was sallow; pulse hard and full, not intermittent; urine slightly albuminous, specific gravity 1017; contained a large quantity of phosphates; memory impaired; gait unsteady; she complained of occasional transient diplopia and constant pain in the forehead. On examining the heart, a rasping *bruit* was heard at the base, accompanying the second sound, and extending along the course of the aorta. With the exception of a few mucous rales, no indications of any morbid condition of the lungs was detected. The diagnosis arrived at was general atheroma, with probable softening of the brain. When about a fortnight in hospital, whilst walking along the ward, she suddenly fell down, and, when taken up by one of the assistants, was found to have lost power over the right side. She was not unconscious, but had partly lost the power of speech. When seen on the next day, her condition was as follows. There were complete paralysis of the right side (limbs, face, and tongue), dilatation of the left pupil, and a well marked flush on the left side of the face, which persisted until her death. When spoken to, she seemed to understand everything that was said, reached out her left hand when requested to do so, and protruded her tongue, which deviated laterally. The power of speech, however, was much affected. She seemed to improve for a couple of days, but then gradually sank into a stupor, from which she could be

roused with difficulty. Gradually, a typhoid condition came on, in which she remained for some days, and then sank.

*Necropsy.*—On removing the scalp and sawing through the calvarium, the diploë in the frontal region was found to be completely absent, the space between the tables of the skull being hollowed out into several thin-walled cavities extending upwards and downwards, and quite empty. The dura mater was healthy; on its removal, a small quantity of fluid distended the pia mater posteriorly. On removal, the configuration of the brain was normal; five ounces of blood and sanious serum escaped during its removal, draining chiefly from the base of the skull and spinal canal. The arteries at the base of the organ were slightly enlarged; their coats of a whitish colour, but not materially thickened. The middle division (the anterior parietal of Duret) of the arteria fossæ Sylvii of the left hemisphere, at its breaking up into two branches, was blocked, a transverse section under the microscope showing it to be filled with granular detritus; the arteries at the right side were normal. The various cranial nerves appeared healthy; the third nerves were, however, very easily detached. The pons, medulla, and cerebellum appeared normal. On examining the hemispheres, the left ascending parietal convolution, for two inches and three-quarters of its length, extending from one inch below the longitudinal fissure into the fissure of Sylvius beneath, was completely softened and broken down into a whitish pulp throughout its entire thickness, the pia mater being adherent to the surface and incapable of being stripped without bringing with it portions of the brain-substance (fig. 6). Beyond a general wasting

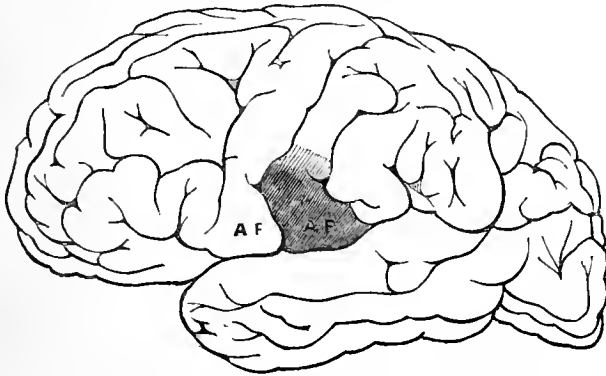

Fig. 6.—Softening of Lower Two-Thirds of the Left Ascending Parietal Convolution; "Foyer" of Softening in the Central White Matter of the Hemisphere.

and separation of the convolutions by wide and shallow sulci, no further cortical lesions, either on this or on the right hemisphere, existed. On cutting into the brain, a "foyer" of softening, circular in outline, and with a diameter of two inches, occupied the centrum ovale of Vieussens of the left hemisphere, commencing two inches and a quarter behind the apex of the left frontal lobe and terminating three inches and one-eighth anterior to the apex of the occipital lobe. This region of softening extended from above the level of the corpus callosum, right through the white matter of the hemisphere, and was continuous with the softened ascending parietal convolution. The intraventricular portions of the opto-striate bodies and the basal ganglia appeared normal. Microscopical examination showed the softened tissue of the cortex to contain numerous granular bodies and broken down nerve-fibres. Many of the ganglionic corpuscles had, however, still retained their normal appearance. A prepared section through the third left frontal convolution revealed a pigmented and granular condition of the nerve-cells and a widely dilated state of the perivascular canals, many of which contained globular debris of nervous disintegration; the majority of the vessels under observation were contracted and shrivelled; their coats were not morbidly thickened. Spots of milary sclerosis were present in great numbers both here and in a section through the left crus cerebri. The heart was enlarged, the walls of the left ventricle being much hypertrophied and covered with a layer of fat. The mitral valves were not apparently diseased; the aortic were puckered and thickened at the edges, and on one curtain was a minute vegetation. The aorta was dilated, and its lining membrane studded with atheromatous patches and cicatrices; the coronary arteries were enlarged and atheromatous; both kidneys were granular on the surface. Microscopic examination revealed hypertrophic thickening of the walls of the arterioles, with a circularly arranged layer of connective tissue externally. The epithelial lining of the tubules was generally present, filling the latter, of a yellowish colour, clouded and granular. Many of the Malpighian bodies appeared to be shrunken and broken. The

condition of the brain in this case was without doubt due to embolic softening of the region included within the area of distribution of the middle division of the arteria fossæ Sylvii (anterior parietal of Duret), aided probably by the general changes in the walls of the vessels. The cortical lesion was strictly located in the left ascending parietal convolution; but, as I have said, the softening was not confined to the cortex, the white matter of the centrum ovale beneath the fronto-parietal convolutions being also involved; and to this must, in all probability, be attributed the extent of the paralysis, though Charcot, indeed, has shown that destruction of a single convolution in the motor zone is sufficient to account for a loss of power in the hand, arm, and leg. Here the localised *ramollissement*, by interrupting the continuity of the conducting fibres passing from the cortical centres to the ganglia beneath, over a wider area than the cortical lesion itself extended, virtually destroyed the activity of motor centres not themselves affected, causing a cessation of function, and, as a result, paralysis of the region which they motorially governed. Softening may exist in certain portions of the white matter of the centrum ovale, without producing paralysis, if such be situated beneath or outside the course of the conducting fibres passing from the cortical motor centres to the ventricular ganglia. Such in all probability was the condition in the case recorded by Dr. Keibell in the *Lancet* for May 5th, 1877, where a tubercular cavity extending for a distance of three inches and a half through the anterior and middle lobes of the hemisphere existed without any motor derangement being present, this softening being probably beneath the level of the conducting fibres to which I have alluded.

These six cases, gentlemen, which I have now related, in all of which localised lesions of the convolutions, either in the non-motor or motor regions, existed, and which were accompanied by negative or positive symptoms, according to the seat of the disease in the non-motor or motor zones, tend, in a greater or less degree, to support pathologically the fundamental doctrines of cerebral localisation, and as a slight contribution to this *questio vexata* of modern medical science, are, I trust, worthy of being placed on record.

#### MENSTRUAL FLUID RETAINED IN THE LEFT FALLOPIAN TUBE, SIMULATING OVARIAN TUMOUR; ABDOMINAL SECTION DURING ACUTE PERITONITIS.

By LAWSON TAIT, F.R.C.S.,  
Surgeon to the Birmingham Hospital for Women, etc.

Miss M., aged 38, was sent to me in the beginning of 1877 by my friend Mr. Alfred Freer of Stourbridge. In November 1876, she had an ill-defined illness, during which she had obscure pelvic pains accompanied by fever. Previously to this illness, she had been in good health and had menstruated regularly. After it, she had severe pain during the whole period of menstruation, and she gradually increased in size until Mr. Freer discovered a pelvic tumour in February last. I found the tumour to be pear-shaped, quite movable, attached to the uterus at the left cornu, evidently unilocular, and about the size of an infant's head. I diagnosed it as a cyst of the parovarium, and advised that it should be tapped after it had increased in size sufficiently to warrant interference. She returned to me in May, with the tumour increased so as to be felt above the umbilicus. I advised her to come again in a month. She came, however, before the expiry of that period, on account of a sudden accession of serious symptoms; and when I saw her on June 20th, there could be no doubt she was suffering from peritonitis. Her pulse was 130; the temperature was 38.4 deg. C. (101.12 deg. Fahr.), and rose to 39.6 deg. C. (103.28 deg. Fahr.) in the evening; and there was excessive pain all over the abdomen, with considerable flatulent distension. I administered opium freely, and applied counterirritation over the epigastrium.

On the morning of the 21st, she was easier, but the temperature and pulse had not fallen. I therefore had her placed under the influence of ether by Dr. A. H. Carter, and proceeded to open the abdomen, assisted by Mr. Priestley Smith. The tissues of the abdominal walls were extremely vascular, and it was necessary to use a large number of ligatures to arrest the bleeding. The peritoneum was found to be intimately adherent to the tumour; and, as soon as the latter had been laid bare for a short distance, it became evident that it was not an ovarian tumour, but presented the red muscular appearance of the uterus. Passing the forefinger of my left hand down as deeply as I could in front of the tumour, with that of my right hand in the vagina, I made out distinctly enough that my original conception of the relations of the tumour to the uterus were perfectly correct.

Under the suspicion that it might be a tubal pregnancy, I did not separate the tumour further, as I had not opened the peritoneal cavity, but cautiously opened the cyst in the middle line by means of a knife. As soon as I had reached its inner coat, I passed my small trocar in and evacuated about six quarts of thick dark brown fluid, having the peculiar smell of menstrual fluid. After the cyst was emptied, I passed my finger through the hole made by the trocar; and to my amazement, I found that the cyst had contracted; and as I kept my finger in the cavity, I distinctly felt it contracting round and grasping my finger. Passing the finger of the other hand into the vagina, I made out that what I had opened was, beyond doubt, the left Fallopian tube, and that I must have opened it close to its fibrillated extremity. I could find no canal leading into the uterus, and did not deem it advisable to make one. I washed out the cavity freely with weak carbolic lotion, by reversing the syphon action of my trocar. The wound was closed by four deep sutures, one of which was so arranged as to fasten in a loop of wire drainage-tube; but before this was done, I acted on a hint from Mr. Priestley Smith and snipped off a piece of the cyst-wall for microscopic examination. This fragment proved to be composed of an abundance of unstriated muscular fibre, conclusively supporting the view that this singular tumour was a distended Fallopian tube. After the operation, I treated her exactly like a case of ovariectomy. Her temperature fell slowly. The wound suppurated freely, and shreds of what was undoubtedly mucous membrane came away with the discharge in large quantity. The drainage-tube was removed on the twenty-first day, and its track continued to discharge till the beginning of August. It then healed, and she is now (October 18th, 1877) in perfect health, save that she has occasional pain in the wound. She has never menstruated since the operation.

From the fortunate issue of this case much is left to speculation, but of the nature of the tumour there is no doubt. As to its origin, it seems to me that it may be accounted for by the supposition that the illness from which all her symptoms dated was a localised salpingitis, which resulted in the closure of the two ends of the tube. The peritonitis, which she undoubtedly had when I operated on her, I suggest was due to a threatening rupture of the tube, and possibly a slight escape of its contents. If this be so, it is evident that it was only the accident of my determination to act promptly which saved the patient's life.

MEDICAL AND SURGICAL PRACTICE IN THE  
HOSPITALS AND ASYLUMS OF GREAT  
BRITAIN AND IRELAND.

SAMARITAN FREE HOSPITAL.

CONSULTATIONS.

**APRIL 26TH.**—*Uterine Fibroid impacted in Vagina.*—Dr. PERCY BOULTON introduced for consultation a young woman who had come from a provincial town for advice concerning an abdominal tumour. On vaginal examination, he found the cervix uteri displaced under the pubes and a firm elastic solid tumour blocking up the pelvis behind it. He reduced the growth and introduced into the vagina a Hodge's pessary to prevent it from falling back again. A sound could be passed three inches into the uterine cavity, and the enlargement then could be felt behind that instrument. The left ovary was enlarged and rather tender. Dr. Boulton desired the opinion of his colleagues on the case and the necessary treatment required, before sending her back to the country. He himself had no doubt that a fibroid tumour existed at the posterior aspect and right side of the uterus. He intended the patient to wear the pessary, and to take ergot, as her periods were profuse and frequent.—Mr. SPENCER WELLS observed that the cervix lay in the normal position, the tumour having evidently been completely reduced by Dr. Boulton. The morbid growth felt like an uterine fibroid, but it might be an enlarged ovary adherent to the uterus.—Dr. BANTOCK believed that the tumour was an extramural fibroid.—Mr. KNOWSLEY THORNTON observed that the tumour had fallen back into the pelvis, the pessary having been removed by his colleagues to facilitate examination. He had no doubt that the disease was fibroid. The remainder of the staff present were of the same opinion; and all agreed to the course of treatment suggested by Dr. Boulton, who again reduced the tumour and replaced the pessary.

*Large Uterine Tumours.*—Dr. DAY called the attention of the staff to the case of a married woman, aged 28. In her right iliac fossa, a firm solid tumour could be detected on palpation. It was freely

movable; and on vaginal examination, the cervix uteri was found to move with it. In the left iliac fossa, another firm but smaller solid tumour could be felt; it moved quite independently of the cervix. Both growths were in all probability fibroid. The patient had menstruated regularly until the last period, which continued eleven days and was excessive. Dr. Day intended to confine the treatment to the administration of tonics.—Mr. SPENCER WELLS had no doubt that the tumour on the right side was a large sessile fibroid growth, whilst that on the left was of similar pathological character, but connected with the body of the uterus by a long, thin, flexible pedicle.—The rest of the staff were of similar opinion.

*Ovarian Tumour; Uterine Adhesions; Supposed Peritoneal Infection.*

—Mr. KNOWSLEY THORNTON requested his colleagues to examine a patient aged 33. In September 1873, she had consulted Mr. Spencer Wells, who detected a hard tense swelling in the left iliac fossa, which felt like a pelvic abscess; but on tapping her, two pints of clear fluid escaped. In February 1874, three pints were removed by the aspirator; in the following November, a pint and a half was withdrawn; on this occasion, the tumour was punctured *per vaginam* by means of a trocar. The fluid was in every case ovarian, both in chemical and microscopical characters; it was clear and of a bright yellow colour at first; but at the last tapping, it looked like turbid beer, the cloudiness being due to immense numbers of inflammatory granular aggregations; ovarian granules were also very abundant. In March 1877, she was again tapped, and twenty-one pints of mixed ovarian and ascitic fluid were removed. Mr. Wells then thought that the connection of the tumour with the uterus was so close that the patient ought to wait till the growth was so large as to compel an operation. In February of the present year, Mr. Thornton tapped the patient at her own house and removed nineteen pints of mixed fluid containing an immense quantity of cell-groups, which he had always found to be diagnostic of peritoneal infection from ovarian growths. He believed that the uterus was so imbedded in the tumour and fixed in the pelvis, and this condition was so clear by combined pelvic and abdominal examination, that not even an exploratory incision was advisable. Then added to this grave complication was the evidence of peritoneal infection, which of course also contraindicated any operation but tapping.—Dr. GREENHALGH questioned the extreme danger of making an incision; but on examining the patient, he thought, considering how firmly the uterus was fixed, that ovariectomy should not be attempted.—Mr. SPENCER WELLS considered that the evidence of peritoneal infection rendered any surgical interference unadvisable; otherwise an exploratory incision might be undertaken to find if there were any possibility of removing the tumour.—Dr. WYNN WILLIAMS had opened the peritoneum for the exploration of tumours, which had been found to be malignant, without fatal results. But as in this case the growth could evidently not be removed, incision was useless.—Dr. BANTOCK remarked that the evidence, in this case, of communication existing already for some time between the cyst and the peritoneal cavity was in itself a most unfavourable complication.—Dr. CHAMPNEYS was also opposed to interference; after frequent tapping the solid parts of the tumour had much increased and become adherent to the uterus; besides, the thickening he could detect in the left vault of the vagina and the fixity of the uterus denoted old inflammatory complications.—Mr. DORAN also thought the case quite unfit for ovariectomy; the physical symptoms were so evident as to render an exploratory incision as needless as it would be dangerous.

*Pelvic Tumour of Uncertain Nature.*—Dr. BANTOCK called attention to a woman, aged 31, who had enjoyed good health till four months ago, when she gave birth to her sixth child. Three days after her confinement, she had a rigor, followed by two more in the course of a few days. She felt no pain till she got out of bed, a month after delivery. Seven weeks ago, diarrhoea came on; the motions were very dark in colour. At present, she feels weak, but is not in pain, and the bowels are not relaxed. The uterus is very high in the pelvis, the cervix is soft, the os patulous. A firm elastic swelling can be detected, immediately connected with the uterus, and extending across to the left iliac fossa; it is quite movable. There is also a slight projection towards the right iliac fossa. Dr. Bantock believed the tumour to be a pelvic hæmatocele. The dark colour of the motions, he thought, aided in his diagnosis. He intended to enforce rest and administer chloride of ammonium.—Dr. GREENHALGH considered that the tumour was made up of the hardened products of pelvic cellulitis.—Dr. WYNN WILLIAMS had seen pelvic cellulitis accompanied with little or no pain, as in this case; but he thought that it would be very difficult to prove by palpation whether the tumour was due to that disease or was a hæmatocele surrounded by indurated tissues.—Dr. CHAMPNEYS was of opinion that the primary affection in this case was pelvic peritonitis, the peritoneum being more involved than the

cellular tissue, for the thickening was high up and followed the reflexions of the pelvic peritoneum; moreover, the uterus was much more mobile than in cases of pelvic cellulitis.

## REPORTS OF SOCIETIES.

### CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 26TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*An Anomalous Mottled Rash, accompanied by Pruritus, Factitious Urticaria, and Pigmentation.*—Dr. A. SANGSTER read a paper on this case. C. F., aged 2, a healthy well-nourished boy, came under notice last August, suffering with an obscure skin-affection. The trunk and limbs were covered, in some places more thickly than others, with a buff-brown and buff-red coarsely mottled rash; the buff-red mottling was most marked on the thighs and legs. Here, the disease presented much the appearance of a measles rash; the parts least affected were the backs of the arms and forearms, the loins, and buttocks; the palms and soles were free; the flexures were specially affected. On passing the hand over the surface, some of the diseased patches were felt to be slightly raised, but this was scarcely noticeable. Nowhere, by pinching up the skin, could any increase of substance be made out. On stretching the skin over the redder patches, the red colour disappeared, leaving a pale buff discoloration. There was much pruritus, especially at the flexures. Scratching led to the production of urticaria wheals. The mother stated confidently that the latter never appeared but as a result of irritation by scratching or rubbing. There were no other lesions of the skin, no papules, blood crusts, or desquamation. The points of interest in the patient's history were, that a grandmother and uncle had psoriasis, that the patient was severely jaundiced in infancy, as was also a younger child, since dead; and that, according to the mother's statement, the patient's skin had always risen in "bumps" upon the slightest irritation. Even handling the child during the process of dressing would cause "the bumps to rise". The eruption had commenced as a red mottled rash on the abdomen when the patient was two months old, and was thought to be measles; however, it persisted, and had gradually spread, first over the trunk, and then to the extremities. As the patches became old, they turned brown. The disease had defied treatment, internal and external. In appearance, this eruption was similar to some others brought before the Clinical Society by Dr. T. Fox, Dr. Barlow, and Mr. Morratt Baker, and judged by Dr. T. Fox to be allied to xanthelasma; while Mr. Hutchinson considered them to be of the nature of urticaria. The essential feature of the disease above described, appeared to be a vaso-motor change in the skin, occurring spontaneously, and also as a result of the most trifling irritation, the above vaso-motor change having a tendency to become permanent, and ultimately leading to pigmentation.

Dr. TILBURY FOX thought the case belonged to the same category as those which Mr. Morratt Baker and he (Dr. Fox) had shown to the Society in 1874, though there was, however, much less, and indeed very slight, elevation of the patches or blotches in Dr. Sangster's instance. In his (Dr. Fox's) *Atlas*, he had figured a patch of the disease, which was flattened and made up simply of apparently dull buff-coloured stains only; and in one of the cases he had recorded, after an interval of five years, the patches had almost subsided, and now only deep-coloured stains remained, so that, under certain circumstances, the patches of the disease were not much elevated. If the Fellows would look at two top figures in plate 60 of Willan's coloured delineations (which he handed round), they would recognise the disease now under discussion; and Willan, in all probability, under what he termed Vitiligo, intended to represent this same disease. He spoke of elevations in the early stage subsiding, and leaving the skin chequered in a curious way; and figured the early red irritable and the late dull mottled pigmented aspects of the disease. Dr. Fox did not think the disease could be called urticaria. It was no doubt liable under irritation to become hyperemic and irritable; but a disease made up of patches, which patches actually remained without much change for years, could scarcely be called urticaria. If the disease were an urticaria, we must completely revolutionise and change our notions of urticaria, as made up of evanescent hyperemic spots connected with vascular spasm. Further, one knew that microscopic examination had shown that the tissue of the skin, in the disease under consideration, was infiltrated with a new cell-growth, like lupus in character. Then, again, the disease might be congenital. The main practical clinical point about the disease to remember was, that it was liable to be mistaken and treated for syphilis, a considerable error which might be fraught with evil con-

sequences.—Mr. HUTCHINSON expressed his pleasure in having seen Mr. Sangster's patient, and heard his clear description. He also congratulated the Society on the fact that it had been the means of bringing under discussion so many examples of such a rare disease. In former sessions, three well-marked cases had been submitted for inspection: one by Dr. Tilbury Fox, one by Mr. Morratt Baker, one by Dr. Barlow, and each case had illustrated a different stage of the disease. The first two were the most severe, the third much less so, and now Mr. Sangster's patient showed it in a comparatively mild and early stage. Taken together, the cases, to any one who admitted that they all represented the same malady, were most instructive, and not far from conclusive as to its real nature. In Mr. Baker's case, the child was covered with brown wheals and ridges, which were in a quiescent state, and from month to month, or even from year to year, underwent but little change; but in Mr. Sangster's case the state of things was different. Here there were the brown stains and some approach to ridges, but scarcely any thickening, and the conditions, although they had lasted long, were constantly undergoing local change; and, above all, there were in addition the very easy production of urticarian wheals. No one who had seen this child's skin, and noticed how the slightest touch sufficed to bring out a wheal, looking exactly like a nettle-sting or a flea-bite, could possibly doubt that, for one thing at least, the child had urticaria. He congratulated the author of the paper on the name employed, "urticaria pigmentosa"; for he had no doubt that it came very close to the truth; and, further, that it was applicable not only to this, but to the other cases. It had been objected that we knew nothing of urticaria as a malady lasting for years; but he believed that, in reality, some of the forms known as urticaria perstans were of quite indefinite duration. Besides, it was not quite literally true that, in these cases, the urticarian stage lasted for many years; it was rather its results in the way of thickening and pigmentation which were so persistent. His theory of the malady was that it was urticaria occurring at an unusually early age, and in connection with some peculiar condition of pruriginous skin; that it was evoked by local causes, and in the first periods kept up by them; and that in the end the skin became permanently thickened and discoloured by the long persistent inflammation. He would further add, as a conjecture, that the original irritation would in all probability be found to be bites of bugs or fleas, or both. He held that it was almost impossible to allow so wide a range of variation for the consequences of bites. As a rule, young infants were not very much irritated by them, but sometimes they were dreadfully affected, and sometimes the consequences were by no means transitory. In Dr. Barlow's case, which he had been permitted an opportunity of examining in the hospital, he believed that he had identified the results of bites.—Dr. SANGSTER said that, in reference to Dr. Fox's observations, the eruption had never been more raised than it was at present. In cases of pruritus, one might generally suppose the pigmentation of the skin was due to the congestion of the skin produced by scratching. In this case, the pigmentation could not be due to that cause, since it began when the child was only two months old. He thought, however, the pigmentation was due to local causes, possibly to the flannel-binder. The child had been in New York, and the mosquito-bites there received did not give rise to any other than the usual effects in the skin. Vaccination also had produced no pruriginous eruption. The child had been jaundiced when very young, and the frequent connection of disease of the liver with innervation of the skin and skin-disease was suggestive.—THE PRESIDENT had not long since seen a gentleman with permanent discoloration of the skin about the face and neck, due to the bites of mosquitoes.—Dr. TILBURY FOX had also witnessed the same thing.

*Cacotrophia Folliculorum (Follicular Malnutrition).*—Dr. TILBURY FOX, in a paper with this title, sought to bring before the profession a disease of the hair-follicles characterised by special features, and clinically distinct from those generally recognised. He had exhibited a drawing of it, with a brief description, at the annual meeting of the British Medical Association at Manchester in 1877; and Mr. Erasmus Wilson had, in his latest course of lectures in January of this year, used the same drawing to illustrate some more detailed and independent remarks. Dr. Fox sketched lightly the pathology of the several popular diseases situated at the hair-follicles, and characterised by retention of exuvie with secondary congestion, by simple follicular torpor, or by primary congestion with its consequences, viz., pityriasis pilaris, lichen pilaris and scrofulous, planus, ruber, and simplex, and he argued that the drawing shown illustrated a condition distinct from any of these. At first sight, it appeared to be nothing more than ordinary but severe lichen pilaris; and in this category, no doubt, it was ordinarily placed, but it differed in its severity, the deeper and more complete affection of the follicles, its congenital nature, its more general distribution, and its obstinacy to treatment. Dr. Fox then

considered lichen pilaris more closely as being the disease in external features most like cacoecotrophia. Willan described lichen pilaris as a "modification of lichen simplex, the papules appearing only at the roots of the hairs of the skin", in fact, as an inflammatory state of the follicles. But most modern writers meant either a follicular torpor due to plugging by epithelial exuviae or altered sebum, or a simple inflammation with exudation into the follicle, especially confined to its upper part, and the consequent formation in both cases of papules pierced by hairs, which remained practically unchanged. It was brought about by many local and general causes, such as uncleanness, local irritants, and blood and constitutional states. Lichen pilaris was not often seen in the very young; it was an acquired disorder, was more or less localised to particular parts, especially the thigh and outer side of the arm and forearm; and, lastly, it was not notably obstinate. The eruption of cacoecotrophia folliculorum was made up of solid red papules, of the size of a pin's head, which were seen to be situated at almost every hair-follicle, and these papules stood out from a rather reddened base. Though the disease had a special predilection for parts, such as the outer aspect of the arm, the back of the shoulders, the thighs, the trunk, and the sides of the face and forehead, which was sometimes the seat of seborrhoea sicca, still, the eruption was of very general and extensive distribution. The hairs had mostly disappeared, those that remained being stunted and twisted, and the interfollicular portion of the skin was reddened, the whole thing often bearing a striking resemblance to xeroderma. In this affection, the deepest portions of the hair-follicle, including the papilla, were affected, and the formation of the hair interfered with. It was not an inflammatory condition, but one essentially of defective or indolent nutrition with plugging of the follicles and some passive congestion. Individuals were affected from the earliest age, or it might be truly congenital, and was not acquired later on in life. A very important point was that the disease occurred in subjects, mostly young women, of a lymphatic, strumous, or phthisical tendency, and was brought into prominence and especially attracted notice about the period of increased physiological activity, viz., puberty. The paper was illustrated with the detailed notes of four well marked cases.

Mr. HUTCHINSON scarcely knew why these cases should be separated from cases of xeroderma or ichthyosis, which was a congenital cacoecotrophy of the whole skin; whereas the disease in the present case was simply a cacoecotrophy of the follicles only.—Dr. WILTSHIRE thought that the disease was rather common amongst insane children of Mongolian type, with clubbed fingers and blue eyes.—Dr. TILBURY FOX, in reply, said he was quite aware that there was a plugged state of the follicles in connection with ichthyosis, but that was not the condition he had described in the paper he had read; and it was not very likely that both he and Mr. Erasmus Wilson should have made a blunder upon so simple a point as that. He doubted if Mr. Hutchinson (at least his remark seemed to show as much) was exactly conversant with the disease under discussion. He (Dr. Fox) did not know of any published account of the condition.

#### HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 25TH, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

THE recommendation of the Council, that the hour of meeting be changed from 8 P.M. to 8.30 P.M., was carried unanimously.

*The Late Mr. T. C. Jackson.*—Dr. LANGMORE referred to the death of the late President, Mr. T. Carr Jackson, and proposed that a vote of condolence be written to his family. This was seconded by Dr. ROYSTON, and carried unanimously.

*Report on Tuberculous Kidney.*—The report of Mr. MORRIS and Dr. GRIFFITHS on Dr. Griffiths's case of tuberculous kidney was read. The kidney was greatly enlarged, and consisted of masses of new growth with spaces in them extending throughout the structure of the kidney until the true secreting structure could scarcely be found. The cones in the pelvis were greatly destroyed. The ureter was also the seat of disease, which involved all its coats and diminished its lumen.—The PRESIDENT said the report left it still somewhat doubtful as to the real nature of the growth, as to whether it was truly tuberculous or not.

*Abnormalities of Fetal Development.*—Mr. AUGUSTUS PEPPER read a paper on the above subject, which he said possessed a practical value not sufficiently appreciated. He said that the development of the tissues of the organism from the three layers of the embryo often led to arrest of development, at other times to supplemental growths. The nervous system, with its membranes and the bones belonging thereto, were often so affected; not rarely the casework remaining in a non-

osseous state. He then gave an account of a case of spina bifida, which at two months began to grow worse; there was also hydrocephalus, with a loss of natural ebb and flow in the cerebro-spinal fluid; pressure on the head not affecting the tumour. In spina bifida, there was some loss of nerve-supply to the lower extremities; or one limb might be less than the other limb. A photograph of a cured spina bifida, with some modification of the ribs, was exhibited. One case which had come under his notice lately had but a small portion of the cranial vault, together with some closed cysts, probably formed from the arachnoid. The formation of these cysts was then described very ably. The first and second cranial nerves, he said, were probably formed from a different embryonic blast than the brain; and fusion took place later on. In another case (foetus exhibited), there were but rudiments of the spinal cord, and the head was entirely wanting; while the nerves of the limbs and the ganglia were perfectly normal. There were also talipes calcaneus, a contraction of a finger, and an extroverted bladder.—The PRESIDENT inquired if there were any mechanical explanation of those arrests of nutrition.—Mr. EDMUND OWEN said these defects were common in first-born children.—Dr. SEDGWICK inquired as to the condition of the thoracic viscera.—Dr. MAHOMED said that the remains of the vessels of the foetal cord were often a source of danger in after-life entangling the bowel.—Mr. CRIPPS LAWRENCE spoke of a child which was born while the mother had scarlatina; it soon died, and was found to have acute endocarditis.—Mr. OWEN related a case of a foetus he saw which had a tail, that was curled up on one buttock and distinctly moved. It was successfully removed by ligature, and was now in the museum of Guy's Hospital. The child lived to sixteen years of age.—Mr. PEPPER replied; and the meeting adjourned.

#### EPIDEMIOLOGICAL SOCIETY.

APRIL 11TH, 1878.

Surgeon-General JOHN MURRAY, M.D., President, in the Chair.

*Plague and Typhus Fever in India.*—A paper on this subject was read by the PRESIDENT (Dr. MURRAY), who said that plague or bubonic typhus was first noticed in India during the present century. It appeared in Kitywar on the West Coast in 1816, and caused great mortality till 1821. It crossed a range of hills, and appeared at Rajpootana at Pali in 1836, and spread to the surrounding towns till 1838. The typhus fever, with prominent symptoms of yellow fever, appeared to extend northward in 1837-8 to the Doab and Rohilkund. In 1836, the plague was reported to be causing great mortality in Gurhwal and Kumaun in the Himalaya mountains. On investigation, it was found that this disease had first appeared in 1823 in Gurhwal, at a temple in Kidarnath, where the people said that it was an infliction from the gods for a neglect by the high priest of the ceremonies prescribed in the Shasters; it killed the high priest and all the Brahmins of the temple, and spread with the pilgrims to the surrounding country. It continued to spread to the surrounding country with occasional aggravations from that date down to 1877. In 1852, a typhus fever, with symptoms of yellow fever, and, in addition, buboes in the groin, axilla, and neck, made its appearance in the hilly country of Eusofzai, about forty miles north of Peshawur, and proved very fatal during that and the following year. A detailed account of the symptoms, as given by Dr. Forbes of Palu, Dr. Farquhar at Eusofzai, and Dr. Plank at Kumaun, showed all the symptoms of plague as described in Egypt and Europe, and all the varieties of and modifications usually found in those countries. A typhus fever, with all the symptoms of yellow fever and occasional suppurations of the glands of the neck, appeared in Saugor in the year 1859; and in 1860 a virulent attack of the same disease broke out in the central prison at Agra, and proved fatal in 313 cases; during the same year, a similar disease in the central prisons of Meerut, Lucknow, and Allahabad proved fatal in 492 cases. In 1863, it appeared at Lahore, and subsequently in other prisons in the Punjab. The disease still appears in the Punjab; the total mortality up to 1875 having been 5,346. The general symptoms in the most intense cases of all these diseases were alike; extreme prostration of body and mind, with torpor, followed by death in twelve or twenty-four hours, leaving no local symptoms of bubo or jaundice, only a black liquid state of the blood. Buboes were early and prominent symptoms at Palu. They did not appear till the fourth up to the seventeenth day in Kumaun; whilst nearly all the cases proved fatal before the third day. In Eusofzai, they did not appear till the eighth or eighteenth day. In the Doab, as in the subsequent jail attack, the glands in the groin were very rarely affected; those in the neck were more frequently affected, but this was not a prominent feature in the disease. In all these diseases, the approach of the hot season checked the attack in the same

manner as plague is arrested in Egypt and Turkey. This was shown in several interesting tables. These diseases were regarded by all the medical officers as contagious and capable of being transmitted from a patient to a healthy person, and all concurred in the dissemination being essentially promoted by crowding, bad ventilation, and defective sanitary arrangements. None of the medical officers engaged in investigating the outbreaks of plague in Kitiwar, Palu, Kumaun, and Eusofzai were attacked by the disease, nor were any of the civil surgeons in charge of the sixty-eight jails in the North-West Provinces and Punjab since 1860 attacked, with one exception, and he recovered. The native doctors and hospital attendants, more especially the sweepers, suffered severely in many instances. The opinion of the inhabitants of Kumaun of the contagious nature of the disease was shown by the practice of deserting the villages where the *bola* or *bubo* appeared, and prohibiting the inhabitants of an infected village from entering their houses. This principle guided the regulations of the Government of India for the removal of troops from cantonments and of prisoners from jail on attacks of cholera or typhus fever. The result in saving life had been very satisfactory; as, had the mortality from European troops from cholera continued during the last thirteen years at the same rate it was the previous years, it would have amounted to 5,340, instead of 1,994 which actually occurred. The disease now proving fatal among the Russian troops in Armenia and Bulgaria under the various names of spotted typhus, black typhus, plague typhus, was probably induced by the same poison as plague, which produced the variety of local symptoms which were modified by season and temperature in India, and for practical purposes would indicate the same course of prophylactic treatment.

BRITISH MEDICAL ASSOCIATION.  
SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT  
MEETING.

MARCH 14TH, 1878.

R. M. MILLER, M.D., in the Chair.

*Diarrhoea from Milk Supply.*—The SECRETARY read a paper by Dr. PHILPOT on an outbreak of diarrhoea in Upper Norwood. One hundred and fifty-six cases occurred within twenty-four hours. It was traced to a particular milk-supply, but further cause could not be traced.—Drs. Miller, Lanchester, Galton, Coles, and Ogilvie made remarks.

*Electrolysis of Scrofulous Lymphatic Glands.*—Mr. GOLDING-BIRD read a paper on the treatment of scrofulous lymphatic glands by the electrolytic caustic. He referred to the general disuse of caustics. He divided cases of scrofulous glands into three classes: 1. The glands free, though enlarged; 2. The glands matted together or to the skin, or presenting hardened nodules, or encapsuled (lymphoma); 3. The condition of active inflammation. The first class was met by general treatment. In the second, it was better to use the knife. In the third, the best operation was by caustic; and the least painful of any mode of applying it was the one now described. A small arrow of sheet zinc, one inch and a half long by half an inch wide, sharp at one end, had a copper wire ten inches long attached to the other. The other end of the wire was soldered to a plate of thin sheet silver or copper three or four inches square. The latter was firmly strapped upon a piece of lint, wet with salt and water, on to the skin somewhere near the spot to be destroyed. Over it was placed some oiled silk or waterproof strapping. The zinc point was then thrust through the fungating mass to be destroyed; a small shield of gutta-percha or cork regulated the length of the zinc point. Some cotton-wool and a bandage were placed over all. The gland was gradually disintegrated by the formation of chloride of zinc at the expense of the metal inserted, and came away in four to six days. When all the gland had come away, the wound rapidly closed with very little scar. The lint must be wetted with salt and water night and morning. Mr. Spencer Wells was employing this treatment for the removal of uterine cancer. He referred to two cases, in which, though the results were very satisfactory, much pain was complained of. In the latter, the total weight of slough was four hundred and thirty-three grains. He narrated the history of one case in which he applied the zinc in the form of a flat disc to necrosed bone with good result.—Dr. HATLEY referred to the importance of the size of the scar.—Dr. HOLMAN remembered the late Dr. Golding Bird applying zinc galvanism to cause healing of ulcers.—Dr. MILLER advocated the use of small puncture in suppurating glands.—Mr. GOLDING-BIRD said that he would not use the caustic when the gland was in a fluid state. His plan was a following out of the lines of his father. He considered that the scar was larger when the knife was used.

*Non-Alcoholic Treatment of Post Partum Haemorrhage.*—Dr. POOLE read a paper on this subject. After referring to the general aspect of

the treatment of disease without alcohol, he quoted opinions of text-books, and contrasted those of Dr. Blundell, "faintness from small bleeding is conducive to its stoppage", and Dr. Denman, "cordials should not be given to those faint from hæmorrhage till there is danger from its long continuance", with Dr. Leishman's statement, that "tendency to syncope must be counteracted by free stimulation with brandy". He referred to ten or twelve cases of large scrotal tumour, upon which he had operated in India, which recovered from excessive hæmorrhage without stimulants. He gave a history of two cases, both in total abstainers. The first patient, aged 40, had a miscarriage at the fourth month. He gave Liebig's extract and a full dose of ergot, and removed the placenta. The fainting condition lasted for hours. In the second case, a multipara with breech-presentation, the forceps was applied, and a large head was followed by a rush of blood. Perchloride of iron was injected without clearing out the clots; the bleeding continued; then the clots were cleared out, and perchloride was reinjected. Liebig's extract was given. If the heart flagged, he would stimulate with a cup of soup. Alcohol was not food.—Dr. GALTON considered that the bleeding, in cases of surgical hæmorrhage, was not comparable with that from the uterus, where the arrest was due more to the muscular contraction than to clotting in the vessels. He should expect more good from alcohol in stimulating muscular contraction, than harm in preventing clots from forming. With reference to the scrotal elephantiasis, operation by Sir Joseph Fayrer's method would have prevented the hæmorrhage, as he (Dr. Galton) had proved in seventeen cases, in the largest of which (weighing fifty pounds) little more than two ounces of blood were lost.—Dr. PARSONS SMITH said that the stimulant was not used to arrest hæmorrhage.—Dr. COLES thought we were often too meddlesome in midwifery. He questioned the absorption of alcohol in syncope, and agreed with Dr. Poole that nature's own remedy was fainting.—Dr. BRAXTON HICKS said that all must have thought whether stimulants were useful in *post partum* hæmorrhage. There were two points as to its arrest: 1. The contraction of the uterus; 2. Coagulation of the blood. The first depended upon whether alcohol increased the vital powers of the nerve. He doubted the increased action of the heart under alcohol; in large quantities, it certainly lessened it. In large doses, it checked uterine contraction; in small, it probably did good. People who did not faint with hæmorrhage came to grief.—Dr. LANCHESTER considered the question from two points of view: 1. When hæmorrhage was going on; 2. When it ceased. In the first, we should be trying to arrest the hæmorrhage instead of giving stimulant. In the second, he thought stimulant helped to keep up action of the heart after injecting perchloride of iron.—Mr. SIDNEY TURNER thought we should stop hæmorrhage before considering alcohol. In the first case mentioned by Dr. Poole, the hæmorrhage ceased after removal of the placenta. He had seen the worst syncope in a case of no hæmorrhage, but large thin uterus.—Dr. BRAXTON HICKS said that secale was the best remedy for this.—Dr. JEAFFRESON was of opinion that the extreme bloodlessness of approaching death was attended by contraction of unstriated muscular fibre. In pig-killing, as a final phenomenon, the animal passed urine.—Dr. HOLMAN considered the question as one of "experience, luck, and pluck". Having lost cases of hæmorrhage, he had not the pluck to stand by and see a patient faint to death. He had observed under stimulant a pulse of 150 come down. Often, not letting a patient die would depend upon moderate stimulation.—Dr. BRAXTON HICKS asked whether any one had tried subcutaneous injection of sulphuric ether.—Dr. MILLER thought there were two points to be considered: 1. The whole profession had abandoned the excessive use of stimulants; 2. Alcohol was the only remedy often at hand, and the objection against its non-absorption would apply also to beef-tea.—Dr. POOLE was still unconvinced. He considered that alcohol did not act upon the uterus.

*Abdominal Tumour.*—Mr. SIDNEY TURNER read a case of abdominal tumour. The patient, a woman aged 45, on October 15th, was seized with shivering. The temperature was 101 deg. to 104 deg. Fahr. for the first week. The pulse varied from 100 to 118. There was pain, of spasmodic character, with tenderness on pressure over the left lumbar and hypogastric regions. An oval tumour, visibly prominent, of roundish outline, occupied the great part of the left side from the ribs to midway between the crest of the ilium and Poupart's ligament; it was dull on percussion. Impacted calculus in the ureter was suggested. The swelling gradually subsided after the appearance of pus in the urine; and on December 5th the patient had completely recovered. No calculus was passed or found in the bladder. The treatment consisted of iron and quinine and good diet.—Dr. JEAFFRESON described a smaller case on the right side. Hydronephrosis was diagnosed. It was tapped, and clear acid fluid with uræa crystals was obtained. In three or four months, the tumour reappeared, and disappeared again suddenly with turbid urine.—Dr. BRAXTON HICKS mentioned a similar case,

with *post mortem* examination, which showed a blocked ureter with distension of the pelvis of the kidney; this, bursting, had formed an artificial ureter from the pelvis of the kidney. He stated that an ovarian tumour was sometimes carried up by a pregnant womb and left adherent, so that resonance below did not necessarily imply that a swelling was non-ovarian.—Dr. MILLER had seen a similar case recurrent from time to time.

*Poisoning by Opium.*—Mr. SIDNEY TURNER read a case of opium-poisoning in a patient aged 65. The dose taken was four ounces and six drachms of the tincture; and, it being supposed to have been taken long before, no stomach-pump was used. Coffee was freely given, and warm clothing put on, with exercise for thirty-six hours; the patient was then allowed to sleep for ten hours. The pupils were contracted for three days, during which the patient took bromide of potassium with *elladonna* to relieve headache. He urged the necessity of keeping up the temperature of the body in these cases.

#### BRITISH MEDICAL ASSOCIATION. YORKSHIRE BRANCH. MARCH 27TH, 1878.

*Tumour of the Brain.*—Dr. SHANN read a case of tumour on the brain in a boy aged 13. The tumour was found lying on the optic commissure, having caused flattening of both optic nerves and of the pituitary body. One-half of the sella Turcica was destroyed, and the other reduced to a shell of bone. The interest of the case was the very slight character of the symptoms and their intermittent character, the local injury being of so permanent a nature. The only indication of disease of permanent and progressive character was the loss of vision, which, from being somewhat impaired, passed gradually into permanent blindness. The only other symptoms were occasional headache and sickness, temporary in duration, spread over eighteen months. He had a fit on two occasions, which passed off without leaving permanent effects. Seven days before death, drowsiness came on, and temporary paralysis of the right arm, which entirely passed away.

*A Pill Swallowed into the Left Bronchus.*—Dr. CLIFFORD ALBUTT related a case in which a pill had been swallowed into the left bronchus. Expansion and respiration ceased in the upper part of the left lung, and violent spasm of the breathing was set up. This was kept under by the continuous use of chloroform for five hours, at the end of which time half the pill was spat up, and the remainder followed in morsels. By the use of the gag, the laryngoscope was easily used during the narcosis. The vocal cords stood very widely open, and almost motionless. Mr. Teale's assistance was obtained during the treatment. The pill swallowed was a coated compound conium pill. The patient was asthmatic.

*Pernicious Anæmia.*—Dr. CLIFFORD ALBUTT related six cases of so-called pernicious anæmia. He said that the disease had not been forgotten in England since Addison's time, as cases of the kind had been under his care twenty years ago as clinical clerk to Drs. Bence Jones and Fuller in St. George's Hospital, and in Addenbrooke's Hospital under Dr. Paget, and were fully recognised by those physicians. The ophthalmic symptoms were described, and the curious relapses attended with vomiting were pointed out. The author thought that phosphorus was the only drug which seemed to be of use, and this only in a minority of cases. He did not think Dr. Fenwick's ingenious suggestion adequate, that this state was due to atrophy of the coats of the stomach.

*Treatment of Hydatid Cysts.*—Dr. EDDISON (Leeds) made some remarks on the treatment of hydatid cysts, and referred to the detailed reports of three selected cases from his own practice in the Leeds Infirmary, illustrating different forms of the disease. His opinions as to treatment, which, he believed, agreed generally with those of most persons having much experience of the disease in question, were as follows. Cysts should be emptied as soon as they are discovered. The fluid should be withdrawn by an aspirator, using a very moderate degree of exhaustion, and a very fine needle should be used. There is no need to attempt to cause adhesions to the external coverings, the abdominal wall or the costal pleura for example. If care be used, the suction of the aspirator does not cause pain; but pain may often be produced by allowing the point of the needle to move about unnecessarily. The cyst should be as nearly emptied as possible; for the less fluid that the punctured cyst contains, the less chance is there of the outflow of such fluid through the puncture. Nothing whatever should be injected into the cysts. As soon as pus is evidently present, an opening should at once be made, and the suppurating cyst be treated as an ordinary abscess, bearing in mind that the cyst-wall and secondary cysts should, if possible, be removed. In one of the cases referred to, a cyst of more than nine years' standing and of large size was expelled

*en masse*, the walls being perfectly clear and transparent, although suppuration had been going on for some weeks.

*Foreign Body in the Eye.*—Mr. SNELL related a case of foreign body (piece of steel) embedded in the fundus oculi close to the optic disc, with retention of perfect sight. The patient was exhibited, and examined by several members. The date of injury was five months ago. Mr. Snell also related a case of foreign body in an eye for twenty-nine years.

*Diphtheria.*—Dr. THOMAS related a case of diphtheria, which terminated in sudden death. The patient was progressing favourably, when, about the twelfth day, severe vomiting came on, followed in a few hours by collapse and death. Dr. Thomas did not consider that the patient had died from thrombosis, cardiac, pulmonary, or aortic, as he did not exhibit any of the ordinary symptoms present when such is the case; he did not think that sufficient evidence had been brought forward to prove that all these cases were caused by cardiac degeneration. Nothing had hitherto been found in the nervous centres sufficient to account for death. Taking into consideration, therefore, that the pneumogastric is a motor nerve of the stomach, and the inhibitory of the heart, and that stimulation of it will retard and at last stop the action of the heart, and at the same time increase the muscular action of the stomach if it contain anything, he was inclined to think that the pneumogastric nerves were irritated in some way, perhaps by the action of vitiated blood upon the medulla, or, as had been suggested, by reflex action through the nerves supplying the parts affected by diphtheria.

*Tumour of Forearm.*—Mr. H. J. KNIGHT related a case of tumour of the right forearm, presenting all the clinical features of a myeloid sarcoma, but really the result of inflammatory exudation and thickening following periostitis of the radius. The subject of it, a youth aged 17, made a rapid recovery after the formation of an abscess and the extraction of a minute shell of exfoliated bone.

*Inversion of Uterus.*—Dr. JAMES BRAITHWAITE (Leeds) related two cases of inversion of the uterus, in the first of which continuous elastic pressure, very firmly applied for four days, produced sufficient reinversion to allow completion of the cure by the hand. All previous attempts at reduction had failed.

*Relaxation of Pubic Symphysis.*—Dr. J. BRAITHWAITE related a case of relaxation of the symphysis pubis following delivery. Movement of the pubic bones upon one another could be felt by the hand, on pressing upward either thigh as the patient was recumbent in bed.

#### GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MARCH 15TH, 1878.

R. SCOTT ORR, M.D., in the Chair.

*Treatment of Acute Rheumatism.*—Dr. CHARTERIS gave an outline of the treatment of acute rheumatism, tracing it from the time of Sydenham and Bouillaud down to the present, when most physicians are testing the value of the recommendations of Dr. MacLagan of Dundee. Dr. Charteris stated that, from November 1876 to January 1878, he had treated twenty-three cases of acute rheumatism in the Royal Infirmary, either with salicin or salicylic acid, in doses of ten to twenty grains every two hours, and he generally found the pain relieved in twenty-four hours. Dr. Charteris also showed an apparatus for testing the amount of urea excreted.—Dr. MCCALL ANDERSON urged the importance of attending to the cause and general treatment of the disease. He could not regard salicin as a specific, although he thought it the best medicine we at present possessed. He found hypodermic injections of morphia useful in relieving the pain.—Dr. GAIRDNER had made extensive trials of salicin, and he had found that no good result could be obtained unless large doses of twenty grains at least were given, and that there were some cases which would not yield to it. He thought we yet required a more accurate classification of cases of acute rheumatism founded on pathological facts.—Drs. THOMSON, REID, MORTON, KENFREW, and TENNENT were of opinion that careful general treatment was of the utmost importance. They had not seen the relief to pain which some observers reported.—Dr. SCOTT ORR had tried the new drug, and in some cases it seemed to suit well, but he was still inclined to trust to acetate of potash.

At a special general meeting of the Birmingham Natural History and Microscopical Society, held on April 30th, Dr. Cobbold, F.R.S., was unanimously elected an Honorary Vice-President of the Society. The appointment was made under Law VIII, in consideration of his distinguished researches in natural science, and for his liberality to the Society. Dr. Darwin is the only naturalist who has received a similar honour.

# BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 11TH, 1878.

### SEWER-COMMUNICATIONS AND FILTH-DISEASES.

DR. JAMES B. RUSSELL, the Medical Officer of Health for Glasgow, in a paper recently read before the Philosophical Society of Glasgow, has made a valuable contribution to our knowledge of the effect of sewer-gas upon the production of enteric fever and diphtheria, two of the most clearly defined filth-diseases. It appears that, since 1873, every fatal case of any zymotic disease or of lung-disease in Glasgow has been entered on a card, upon which has also been recorded, after inquiry, "minute details about the size of the house, the position of the water-closet if there be one, and also of the ashbox or sink". During the three-and-a-half years ending December last, 420 fatal cases of diphtheria and 833 of enteric fever have been dealt with in Glasgow on this detailed card system, and form the basis of Dr. Russell's investigation undertaken with a view to calculate the effect of sewer-communication in the production of these diseases. For this purpose, the houses in which these deaths from enteric fever and diphtheria were recorded were divided into four classes: (1) those having a water-closet inside, with or without a sink; (2) those having a sink inside, but no water-closet; (3) those having no connection whatever between their internal atmosphere and the sewers—that is, having neither water-closet nor sink; (4) and those concerning which, from the addresses not being found or other causes, the information was not obtained. The investigation, for reasons which it is here unnecessary to dwell upon, was confined, so far as it deals with the influence of sewer-gas, to houses of one and of two apartments. The total number of houses of each size in the city was obtained from the City Assessor's annual assessment-roll; and the proportions of the houses of each of the four classes above mentioned was determined from a return called for by Dr. Fergus in 1872, showing the numbers and the class of the houses having water-closets, drains, etc., in communication with the sewers. In order to ascertain the numbers of persons living in these houses of different sizes, Dr. Russell assumed that the average number of inmates of the houses in each class prevailing at the census in 1871 is still maintained. It may be stated that, in one way or other, the internal atmosphere of fully 33 per cent. of the one-apartment and of 69 per cent. of the two-apartment houses was in communication with the sewers.

Dr. Russell set himself to answer the following questions. Does it make any difference to the inhabitants of a one or two apartment house, whether there is or is not a communication between the house-air and the sewers? Are the residents of these houses, or are they not, more liable to be fertilised with the germs of these two special filth-diseases? The number of houses of one apartment having an internal water-closet was too small to afford a trustworthy basis for calculation; but, among those persons living in houses of one apartment having no communication with the sewers, the death-rate per million was equal to 120 from diphtheria, and to 249 from enteric fever; whereas, among the residents of one-apartment houses containing a sink-communication with the sewer, the rate from diphtheria was equal to 253, and from enteric fever to 677, per million. So, in the houses of two apartments having "no direct means of access for the specific germs", the rate from diphtheria was 127, and from enteric fever 386, per million; in those

having a sink, the rates became 275 and 465; while in those having an inside water-closet in addition to the sink, the death-rate from diphtheria rose to 418, and from enteric fever to 665, per million. Thus it seems to be proved that in Glasgow, during these three years and a half, the lowest death-rates from diphtheria and enteric fever occurred in those houses of one and of two apartments having no communication with the sewers; while the highest rates were found in those houses of two apartments which were provided both with water-closets and sinks. The mortality from each of these diseases was, however, found to be still higher in houses of three apartments; but, as the proportion of this class of houses provided with sewer-communications is unknown to Dr. Russell, he was unable to deal with their statistics so completely as he did with those of one and two apartments. As, however, the proportion of internal sewer-communications rose from 33 per cent. in the houses of one apartment to 69 per cent. in houses of two apartments, it is only reasonable to assume that three and four apartment houses are still more fully provided with internal sewer-communications. Hence, probably, the still higher death-rate from these diseases, the specific germs of which conclusively appear to be distributed by sewer-gas. Dr. Russell expresses his conviction, which is fully warranted by his carefully compiled statistics, that it is the absence of the sewer-connection by sink and water-closet with the internal atmosphere of a large proportion of the one and two apartment houses which causes the death-rates from diphtheria and enteric fever to be lower in these than in larger houses. He further says: "If every house of each size were connected alike with the drains and sewers, then I am sure the diseases specially associated with such misplaced connections would conform to the general law of other diseases, and be at their maximum in the smallest houses."

Dr. Russell concludes his valuable paper by stating that, if we would reduce the mortality from diphtheria and enteric fever to the "lowest possible minimum", not only must all internal communications with the sewers be as far as possible abolished, but our sewers and house-drains must be ventilated on the separate system, and the use of cistern-water for dietetic purposes must be entirely discontinued. There is no reason to doubt that what Dr. Russell has proved with regard to the mortality from diphtheria and enteric fever in Glasgow is more or less true with regard to their mortality in other sewered towns. It is, however, to be feared that but few medical officers of health have provided themselves with the materials for so valuable an investigation as that which has been so carefully elaborated by the indefatigable Medical Officer of Health for Glasgow.

### A STRANGE CORONER'S INQUEST.

ON several occasions lately, we have commented on Coroners' inquests as they are conducted in England. The peculiar conduct of many of these officials, who have won their position by the votes of free and independent electors, has formed a frequent subject of criticism. We do not remember, however, to have met with any case in which the defects of the present system of conducting these inquiries have been more strikingly displayed, than in an inquest lately held at Ruthin on the body of a child alleged to have died from starvation and neglect. We have waded through seven columns of a report published in a local paper, with a view of placing before our readers an abstract of the case; but the proceedings were conducted in so irregular a manner, that we find it exceedingly difficult to carry out this design.

The first inquest was held on the 13th, and the second, by adjournment, on the 20th of April. On the first occasion, the coroner, a member of the medical profession, threatened to commit, for contempt of court, a solicitor and a sanitary inspector; and on the second he threatened to commit one of the jury who had taken an active part in the proceedings. No order was kept in the court; the coroner and jury placed themselves in the position of witnesses, and in complete antagonism to each other; and from the beginning to the end, the

proceedings involved a continual wrangle between the coroner, jury, and other persons concerned in the case.

The facts go into a small compass. A child aged under two years, the illegitimate offspring of an imbecile pauper woman, died under circumstances which demanded inquiry. The body was emaciated, free from fat, and presented the usual appearances indicative of starvation. There were ulceration and sloughing of the left foot; the clothing was insufficient; and the body was infested with vermin. There was, it is said, no natural disease to account for death or for the emaciation. The child was too young to provide nourishment for itself; and the question, therefore, was simply whether the mother, who was a pauper, or the guardians of the poor, were responsible for its death.

There was evidence that the mother had an insufficient supply of milk, and was without the means of procuring food. The responsibility for its death, therefore, appeared *prima facie* to rest with the guardians. Had the case been before a stipendiary magistrate, or one having an ordinary acquaintance with the rules of evidence, the examination of one or two witnesses would have sufficed to show where the responsibility lay. Had the guardians a knowledge of the child's condition; and was it at the time of its death under their custody? The state of the body showed the absolute necessity for proper food and shelter. On these material points, the evidence was most confused and unsatisfactory. After a summing up by the coroner in favour of the mother, the following verdict was returned by the foreman: "Died from starvation and want of proper care; and we find no blame attached to the mother." We give what followed in the words of the report, but abbreviated.

"Several Jurors: We said nothing whatever about the woman.—Mr. Joyce: Our unanimous verdict was, that 'the child died from starvation and neglect'. We say nothing as to who is to blame; we leave that to somebody else.—On the formal 'inquisition' being produced to be signed, some of the jurors demanded it read. The coroner read it, and it stated something about the death being through the inclemency of the weather. Mr. Morris, Mr. Jones, and Mr. Joyce (three of the jury), uttered exclamations of surprise, and declared that they had said nothing about 'the inclemency of the weather'.—Coroner: Don't I tell you this is only the inquisition, and it must be put in legal form.—The Jurors: Well, we won't sign that; we said nothing about the weather.—The document was again read, and said the child died from 'want of the common necessities of life'.—Mr. Joyce and others: Good gracious, Mr. Coroner, that is not our verdict at all.—Coroner: Don't I tell you that the inquisition must be put in proper form. Continuing to read from the document, he said, 'And the jurors say that the deceased came by his death by no violent ways or means whatever'.—Several Jurors: Why, there is not a word of our verdict there; it's altogether a different thing.—The coroner again tried to argue with the jury that that was the proper form for the verdict; but they persisted that they would not sign anything but the verdict. The coroner then handed to the foreman the piece of paper on which the jury's words, 'Died from starvation and neglect', were written; and directed him to sign that.—Mr. Jones: That won't do. We had better retire again and make a verdict for ourselves.—Mr. Morris: I don't understand, Mr. Coroner, why you don't put our verdict into that document, and not what you have got written there.—Eventually, after arguing with them for a long time, the coroner struck out some of the sentences they objected to, and put in that the death was through neglect. The foreman and four or five jurors signed the document. On it being passed to Mr. Morris, he read it through most minutely, and was joined by the coroner, who said it must be put in proper form.—Mr. Morris (pushing the document from him): I won't sign it. I won't agree to that as one of the twelve. Our verdict is there, on that piece of paper; and, if you embody that in a formal document, I am ready to sign it. [Hear, hear.]—After some further cross-firing, the verdict was made to read that 'the said Edward Davies, on the 7th April, died from starvation and neglect'. This document was signed by the foreman, and, on it arriving at Messrs. Morris, Joyce, Jones, etc., they carefully looked it over before signing it. This inquiry, which is admittedly one of the most remarkable that has, perhaps, ever occurred in the district, was thus brought to a close."

The amicable relations of the coroner and the jury are well brought out in this quotation. It is satisfactory to perceive one glimmering of common sense in this discussion; namely, that an inquest should be

really for the purpose of determining the cause of death, leaving the question of who is the criminal to another tribunal. The perusal of the proceedings shows that the coroner and jury had the most eccentric and imperfect ideas of their duty in an inquiry of this kind. The coroner, in his altercations with the jury and witnesses, and with his repeated threats of imprisonment to those who differed from him, appears to have lost all sense of self-respect. The jury, under such guidance, were not likely to take a calm and judicial view of the facts; and hence the difficulty of fixing upon any verdict in the case in which all would agree.

The report of this inquest shows that some legislative enactment is absolutely required to improve the method of inquiry into the causes of death. It is a disgrace to our system of jurisprudence that such occurrences as these should be possible under the sanction of law.

---

PRESENTATION-DAY at the University of London is fixed for Wednesday, May 15th, at 2 P.M.

---

DR. VOLKMANN has been appointed Rector of the University of Halle for the year 1878-79.

---

THE fiftieth anniversary of the doctorate of the celebrated zoologist, Dr. von Siebold, was celebrated in Munich on April 22nd.

---

It is intended to hold a public celebration of the completion of the fortieth year of professorship of Dr. Schwann, at Liège, in the end of June.

---

JULIA FRAM BROWN, a woman who had carried on business in Brighton as a herbalist, has just been committed for trial on a charge of feloniously administering drugs to women.

---

THREE deaths from yellow fever are reported as having occurred on board a Norwegian brig just anchored in the Dover Roads during a voyage from Rio de Janeiro.

---

THE pay of an assistant-surgeon in the American army is sixteen hundred dollars (£320) a year on entering the service, with an increase for every completed five years; also travelling expenses, quarters free, and forage.

---

DURING the American war, we had occasion to refer to the details of charges brought against the Surgeon-General of the Northern Army, Dr. W. A. Hammond. Upon reviewing the charges made and the evidence adduced, we came to the conclusion that this was a political attack, and that the charges were unproven and in no way affected the character of Dr. Hammond. Nevertheless, Dr. Hammond was removed from office. We are glad to see that, by a tardy and incomplete act of reparation, the name of Dr. W. A. Hammond has, by special act of Congress, been placed upon the list of retired surgeons-general.

---

THE names of various Fellows have already been mentioned as probable candidates for the Council of the Royal College of Surgeons. We understand that Sir Henry Thompson has decided to offer himself for the next election. His friends have urged him to take this step, inasmuch as his position on the list is at the present moment senior to that of the other candidates, and the time for his candidature has, therefore, obviously fully come. Sir Henry Thompson has precedence, we believe, of any candidate whose name has yet been mentioned. He became a Member in 1850, and a Fellow in 1853, and is, therefore, on the score of seniority, distinctly called upon to come forward now. Sir Henry Thompson's eminence in the profession and varied ability are so well known as to need no observation, and there seems little doubt that his friends are well advised in nominating him on this occasion. Mr. Callender, whose name has been mentioned as a probable candidate, will, we are informed, not come forward this year.

DR. BROWN-SÉQUARD has been nominated Professor of Physiology in the College of France, in succession to Claude Bernard. Being, however, a British subject (born in Mauritius), he must be naturalised in France before his appointment can be confirmed.

THE vacancy caused by the resignation by Dr. E. Mackey, of the office of Physician to the Queen's Hospital, Birmingham, has been filled by the appointment of Dr. B. Hunt.

THE annual general meeting of the Poor-law Medical Officers' Association was held last week, at the Freemasons' Tavern; Dr. Joseph Rogers in the chair. We will give an account of the proceedings in next week's JOURNAL.

WE have it on the authority of the *Army and Navy Gazette* that, since the beginning of the present year, fifty-two of the leading surgeons of the Russian army have fallen victims to the typhus epidemic. The number is equally distributed between the European and Asiatic seats of war.

DR. WILLIAMSON of Ventnor has received a letter from Admiral Fanshawe conveying to him the thanks of the Lords Commissioners of the Admiralty for the care and attention which he bestowed upon the survivors from the *Eurydice*.

MR. SPENCER WELLS will commence his course of six lectures on the Diagnosis and Surgical Treatment of Abdominal Tumours, in the theatre of the Royal College of Surgeons, on Monday, June 10th; and on the 24th, Mr. B. T. Lowne will commence his course on the Physiology of Nerve-Stimulation. With the latter course, the lectures of the College will terminate for the present session.

THE Council of the Metropolitan Counties Branch have summoned a special general meeting of the members of the Branch, at 11, Chandos Street, Cavendish Square, on Wednesday next, May 15th, at four o'clock, to consider various questions of medical reform in connection with the Bills for the Amendment of the Medical Act now before Parliament.

THE multiplication *usque ad nauseam* of special hospitals makes it all the more important that those which have attracted a large number of cases should, as far as may be, compensate for some of the social harm which they do by indiscriminate pauperisation of the working classes and lax administration of gratuitous advice to the well-to-do, and for some of the scientific harm which they do by drawing away a great number of instructive cases from the centres of medical education. The Brompton Hospital for Consumption and the Children's Hospital in Great Ormond Street have for some years rendered good service to medicine, by the excellent courses of clinical teaching and clinical lectures which have been organised there. The Throat Hospital in Golden Square has now followed the example; and special courses are announced by Dr. Semple, Dr. Whistler, and Dr. Prosser James; while Dr. Semon has organised courses of clinical instruction in the use of the laryngoscope, in which he is an adept.

A SIMILAR course is being adopted at the St. John's Hospital for Skin-Diseases; but, as if at once to illustrate the abuses often connected with special institutions of the kind, these clinical lectures have been made at the outset the occasion of offensive puffs in the daily papers, preliminary to and concurrent with their delivery. We willingly attribute the appearance of these vulgar and most objectionable puffs to the officiousness of some lay officer of the institution; but certainly the surgeons owe it to their own reputation and to the loyalty to their profession, to see that a stop is at once peremptorily put to them.

So admirable (says the *Army and Navy Gazette*) in every respect has the new magazine equipment—the invention of Surgeon-Major Oliver—been found, that, though there was a disposition at the War Office

to discourage it on account of the expense which its adoption would entail, it may now be considered certain that, ere many years are over, it will have entirely superseded the present valise, which, though an immense advance on the old knapsack, has one serious defect in the great difficulty which is experienced in fitting, in consequence of the complicated nature of the straps. Dr. Oliver's invention is as near perfection as can be, and from the first has been most favourably received by the military authorities at the Horse Guards, who have only succeeded in getting it issued to a couple of regiments after the most persistent advocacy of its merits.

#### MEDICAL TEACHING IN CAMBRIDGE.

THE Regius Professor of Medicine at Oxford must, one would think, experience very singular mental emotions on reading the report of the Regius Professor of Medicine at Cambridge at a meeting of the Senate of that University on May 7th to discuss a report of the Studies Syndicate (see page 693). Dr. Paget is as active in inducing Cambridge to fulfil its obligations to medicine as Dr. Acland is energetic in inducing Oxford to forego hers. Dr. Acland found great resources available for medicine, and has helped to divert them. Dr. Paget is successfully inducing Cambridge to apply fresh funds and fresh power to the urgent academic duty of fostering studies in all the subjects in which it examines. The contrast is too dramatically striking not to arrest attention.

#### THE ROYAL ACADEMY.

THE exhibition this year again contains contributions by members of the medical profession. Mr. J. L. Probert's etching, "The Shipwreck" (1222), has a great deal of dash and spirit. Dr. Evershed sends a portrait of a horse (1314). Sir Henry Thompson's "Chapel at St. Mark's, Venice" (180), is clearly and carefully painted. In sculpture, Mr. J. H. Thomas has a bust of Dr. Carpenter, in which the tense expression of the mouth and the corrugation of the thoughtful brow are well brought out. Mr. Woolner exhibits a bust of Mr. Simon, which expresses mixed determination and concentrated thought. The same artist has a bust of Professor Huxley, which is a faithful likeness. Mr. H. P. Macarthy shows an excellent likeness in terracotta of Dr. R. Barnes. The Medal of the British Medical Association is shown by Mr. Wyon.

#### BRITISH DEGREES AND COLONIAL PRETENSIONS.

JUST now, when we are very properly arranging to give privileges of practice in Great Britain to colonial graduates, may be the proper time to secure the like privileges for our own graduates, who in some colonies suffer from the application of a strictly protectionist system by indigenous examining boards. The *Canadian Medical Journal* points out:

"If, however, we ask for our graduates the privileges enjoyed in England by home-graduates, we must at least be prepared to concede something in return. It seems that there is amongst our Ontario Medical Council a feeling of jealousy that makes them resent a man's going over to Great Britain and obtaining his qualifications there rather than here. It is looked on as a slight to the College, and as an attempt to set it at defiance, and is punished by a refusal to register his British qualifications without further examination here, on the ostensible ground that these qualifications are conferred by irresponsible close corporations, instead of, as here, by a body chosen by the profession and responsible to it for the proper performance of its duties."

The assumption of superiority which covers the special pretension of the Ontario Medical Council is not a little amusing; nor is it altogether uninteresting to note how the exaggerated talk which is sometimes heard afloat "irresponsible close corporations" is taken *au grand sérieux* by our colonial offspring, who delight to flout their grandmother with her supposed shortcomings, on however slender evidence. The fact is, that there is no such thing in the three kingdoms as an "irresponsible close corporation" of medicine, so far as we are aware; not one which is not responsible to its own Fellows, to the General Medical Council, and to Government. But, in any case, the joke of a Canadian board turning up its nose at English diplomas, and refusing

to admit them to registration, is too funny to be serious, and too nearly serious to be treated as altogether humorous. We are surprised that this "want of reciprocity" was not mentioned lately at the Medical Council, when the subject of colonial degrees was being discussed.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.** THE annual general meeting of the Society was held on Wednesday, April 24th, at 5 P.M., by the kind permission of the Royal Medical and Chirurgical Society, in their rooms, 53, Berners Street. The chair was taken by Mr. J. Gregory Forbes, Vice-President. A letter was read from the President, Sir George Burrows, expressing his regret that absence from town would prevent him from presiding at the meeting. From the statement of the affairs of the Society read by the Secretary, it appeared that during 1877 a sum of £2,949 had been voted to the widows and orphans—£63:10 in excess of the grants of 1876. The expenses of the year were £187:0:11—£27:15 less than those of the previous year. The receipts, with the exception of legacies and entrance-fees, all showed an increase. The interest on funded property had been £2,576:1:1; subscriptions, £519:15; entrance-fees, ten guineas; donations, £111:4. Only one legacy had been received during the year; viz., £250 from the executors of James Graham, Esq. The funded property had been increased by the purchase of £593:19 Metropolitan Consolidated Stock. The Society had lost twenty-two members by death during 1877, and four members had resigned. Among the deaths were mentioned those of Sir W. Fergusson, Vice-President; George Cooper, Esq., Vice-President; and Dr. Carr, a Director. Only nine new members were elected. At the end of the year, the Society consisted of three hundred and eighty-five members. During the year, fresh applications had been received from six widows and two orphans; four widows had died or become ineligible; and three orphans had ceased to receive grants. On December 31st, there were sixty widows and ten orphans receiving assistance from the Society, and four orphans on the Copeland Fund. The following gentlemen were elected directors, in the place of the six senior who retired by rotation; viz., Dr. Barnes; Dr. Taylor; A. Willett, Esq.; George Eastes, Esq.; Dr. Andrew; and J. Langton, Esq. A vote of thanks to the editors of the medical journals, for their kindness in forwarding in every possible way the objects of the Society, was carried unanimously. A vote of thanks to the Chairman closed the proceedings.

#### CHLOROFORM-DEATHS.

CASES of death following anaesthesia by chloroform administered for dental purposes are multiplying in America. The following is the verdict of the jury: "The jury find that Elizabeth Neely came to her death March 20th, 1878, at No. 224, North Tenth Street, by chloroform administered by H. G. Winslow, M.D.; and we find the said Dr. Winslow guilty of criminal ignorance in administering so powerful a remedy, not having made any examination of his patient." Winslow was really a graduate in medicine, and five out of the six jurymen were also regular graduates. We believe that protoxide of nitrogen has now pretty universally superseded ether and chloroform for dental purposes in this country; and we are surprised to note, from the fatal cases recorded at New York and Philadelphia, that chloroform appears still to be much used there by dentists, and with culpable recklessness.

#### VOLUNTEER SURGEONS.

A CORRESPONDENT writes to us:—I enclose circular, a copy of which you may not have seen. I think, as volunteer surgeons, it is our bounden duty to undertake these duties at the present crisis, provided during the discharge of them we hold the same rank, etc., which an army surgeon of the same date of commission would hold. You will observe it states *under* any medical officer. Now, we cannot be expected to work under men who might be many years our juniors not only in their profession, but also in the service, as volunteer surgeons *vs.* army surgeons. Besides, surely most volunteer surgeons have had sufficient experience in practice to be able to take charge of a few men

without an army surgeon to advise them. Of course, there could be no objection to serve under our seniors. If you called attention to this question in the JOURNAL, you would do the volunteer surgeons a service.

"Army Medical Department, War Office, 30th April, 1878.

"Sir,—As it appears to me desirable that there should be a closer connection between the Army Medical Department and the medical officers of the volunteer force, I have the honour (as President of the Volunteer Ambulance Committee) to request that you will inform me if you are willing to undertake local professional duty under the direct supervision of the Director-General, Army Medical Department, whenever your services may be required, either with troops and their families, or in military hospitals under army medical officers, or even in their absence. You will quite understand that it is not the intention that such duty should remove you from your regiment or interfere with your private practice. A similar letter has been sent to every medical officer of the volunteer force; and, on receipt of their replies, if favourable, I intend to submit to the Director-General, A.M.D., a proposal for the formation of a Volunteer Medical Department, to be referred to the Inspector-General, Auxiliary Forces, for the consideration of the Secretary of State for War.—I have the honour to be, sir, your obedient servant,

"WILLIAM MUNRO, Surgeon-General, A.M.D."

#### COMPARATIVE BIRTH-RATES.

A RETURN just published in the *Journal Officiel* displays the interesting fact that, while France in 1876, with a population of 36,000,000, had an increase of 132,000, England, with a much smaller population (24,000,000), had an increase of 205,000; the rate being in England 1 in 28 inhabitants, and in France 1 in 36. That the population in France does not increase as rapidly as in other countries is a well-known fact, and the figures we have quoted are the latest record of the fact. During the year 1876, the births in France numbered 966,682, exclusive of those still-born; and the deaths to 834,074. The still-born numbered 44,680, and the marriages 291,366.

#### A SOVEREIGN'S GRATITUDE.

A TELEGRAM published in a morning contemporary informs us that on Monday last Mr. Barrington Kennett, Commissioner of the Stafford House Committee, had an interview with the Sultan of Turkey. His Majesty thanked him very cordially, and desired that it might be made known how deeply grateful he felt to the British nation for all it had done for his suffering people and soldiers, and to all who had taken the lead in charitable efforts. His Majesty asked for a list of the Stafford House surgeons, and specially requested that they might each be thanked in his name.

#### RAGS AS DISSEMINATORS OF DISEASE.

AS during the campaigns of 1849, 1850, and 1855, when cholera first appeared in the camp, and afterwards made a tour of Europe, the close proximity of the scene of strife to Austrian ground has caused the government of that country to devote some attention to the outbreaks of epidemics and their means of propagation. A case of spotted typhus has been reported at Kronstadt; while Trieste and Venice, always in active communication with the Levant, have developed some cases which give rise to grave suspicion. Among the measures taken by the Austrian Government to prevent the spread of disease is to obtain the adoption of uniform precautions in all the neighbouring states, in the shape of the strict enforcement of sanitary regulations, and the prohibition of the importation of rags and other things capable of spreading disease-germs. The authorities of Austria have for some time past wisely forbidden the importation of rags.

#### MEDICAL USES OF THE TELEPHONE.

WE have already recorded various experiments and suggestions with reference to the medical uses of the telephone. It has been in use in the house of a medical man during the last few weeks, to enable a member of the family suffering from an infectious exanthem to communicate with her family and friends; and this application we would recommend as very practical to the managers of fever-hospitals and

asylums. In the *Boston Medical and Surgical Journal*, we read that its utility in the class-demonstration of auscultative signs of disorder of the chest is being studied, with good promise of success. Professor Da Costa made a preliminary trial in March last, at the Pennsylvania Hospital, of a Bell's telephone constructed by Dr. W. B. Hopkins, a former resident. It was tested by cases of cardiac murmurs and different varieties of respiration; and, while the results obtained were not fully satisfactory, it was believed to be demonstrated that a slight modification in the construction of the instrument, enabling it to respond to more delicate impulses, would fit it for the purpose, and make it an almost indispensable adjunct to the clinical amphitheatre.

#### DR. RICHARDSON AND THE DENTAL PROFESSION.

THE annual distribution of prizes to the successful students of the National Dental Hospital and College took place at the Langham Hall, Great Portland Street, on May 2nd. After the presentation, Dr. B. W. Richardson, who presided, said he remembered that, at the time of the starting of the school, the profession of the dentist was not affiliated to the medical profession, which he regretted was now the case. He believed that, if the effort which was originally made to establish a College of Dentists had not been hampered by petty jealousies, they would now have had an institution that would have rivalled any of the medical colleges. He cared little for medical reform, for he had seen but a small amount of good come from the effort to obtain it, especially while there existed such a body as the Council of Medical Education. Never mind these examining bodies or quacks. If they could only make their profession certain, all else was certain. Did they want legal protection in anatomy or physiology against quacks? If they were masters of their profession, the difficulty that now arose in respect to any legislative measure for their protection would vanish, and the able man would take the foremost place.

#### PREVENTION OF SCURVY.

ON Tuesday last, at Plymouth, William Owens, master of the ship *Chyrolite*, was fined the lowest penalty of forty shillings, for providing an insufficient supply of limejuice during the voyage of his vessel from Cardiff to Aden, thence to Calloa. Scurvy broke out among the crew when the supply ceased, and some of the men had on their arrival to be sent into hospital.

#### THE PUBLIC HEALTH.

DURING last week, 6,483 births and 3,776 deaths were registered in London and twenty-two other large towns of the United Kingdom. The mortality from all causes was at the average rate of 24 deaths annually in every 1,000 persons living. The annual death-rate was 29 per 1,000 in Edinburgh, 28 in Glasgow, and 32 in Dublin. The annual rates of mortality per 1,000 last week, in the twenty English towns, ranged in order from the lowest, were as follow: Leicester, 15; Brighton, 19; Hull, 19; Bradford, 19; Bristol, 20; Newcastle, 20; Nottingham, 21; Leeds, 22; Portsmouth, 22; Wolverhampton, 22; London, 23; Oldham, 23; Manchester, 23; Norwich, 23; Birmingham, 24; Sunderland, 24; Liverpool, 25; Sheffield, 26; Salford, 27; and Plymouth, 30. The annual death-rate from the seven principal zymotic diseases averaged 3.8 per 1,000 in the twenty towns, and ranged from 1.0 and 1.1 in Brighton and Hull to 6.3 in Oldham, 6.7 in Sheffield, and 7.8 in Plymouth. Measles and scarlet fever are fatally prevalent in Oldham, scarlet in Sheffield, and measles and whooping-cough in Plymouth. Small-pox caused 60 deaths in London and 1 in Bradford. In London, 2,702 births and 1,545 deaths were registered. Allowing for increase of population, the births exceeded by 193 and the deaths by 37, the average numbers in the corresponding weeks of the last ten years. The annual death-rate from all causes, which in the three previous weeks had been equal to 27.6, 25.9, and 24.2 per 1,000, further declined last week to 22.5. The 1,545 deaths included 60 from small-pox, 29 from measles, 27 from scarlet fever, 10 from diphtheria, 117 from whooping-cough, 29 from different forms of fever, and 23 from diarrhoea; thus to the seven principal diseases of the zymotic class

295 deaths were referred, against 346, 323, and 305 in the three preceding weeks. These 295 deaths were 58 above the corrected average number from the same diseases in the corresponding week of the last ten years, and were equal to an annual rate of 4.3 per 1,000. The fatal cases of whooping cough, which had been 157, 123, and 136 in the three previous weeks, declined to 117 last week. The deaths referred to fever, which had been 32, 26, and 24 in the three preceding weeks, rose again to 29 last week, and were within 1 of the corrected average weekly number. Eighteen deaths of infants under one year of age were referred to diarrhoea (in addition to one fatal case of infantile choleraic diarrhoea in South Hackney) against 9 and 5 in the two previous weeks. The deaths from small-pox, which had been 80 and 63 in the two preceding weeks, further declined to 60 last week; 35 were recorded in the Metropolitan Asylum Hospitals, 6 in the Highgate Small-pox Hospital, and 19 in private dwelling houses. Of the 60 fatal cases of small-pox, 33 were certified as unvaccinated and 10 as vaccinated; in the remaining 17 cases (of which 12 occurred in private practice) the medical certificates did not give any information as to vaccination. The deaths referred to disease of the respiratory organs, which had been 497, 398, and 345 in the three preceding weeks, further declined to 284 last week, and corresponded with the corrected weekly average; 162 resulted from bronchitis, and 93 from pneumonia. Different forms of violence caused 60 deaths; 53 were the result of negligence or accident, including 22 from fractures and contusions, 2 from burns and scalds, 11 from drowning, and 10 of infants under one year of age from suffocation. In Greater London, 3,282 births and 1,805 deaths were registered, equal to annual rates of 38.5 and 21.2 per 1,000 of the population. At the Royal Observatory, Greenwich, the duration of registered sunshine in the week was 35.8 hours, the sun being above the horizon during 103.4 hours. The recorded duration of sunshine was, therefore, equal to 35 per cent. of its possible duration.

#### MEDICAL SOCIETY OF LONDON.

ON Monday last, there was a large and influential gathering at the house of the Medical Society of London to hear the annual oration, which was delivered by Dr. Alfred Carpenter. The subject chosen was *Alcoholic Drinks, as Diet, as Medicine, and as Poison*. The President proposed a vote of thanks to the author, which was carried by acclamation. During the *conversazione* which followed, the band of the Royal Artillery, under the direction of Mr. Smyth, the bandmaster, played a choice selection of music, and there was also some excellent glee-singing. This innovation appeared to meet with the cordial approval of the company present. A few objects of interest were exhibited, among which was a parabolised illuminator by Dr. Edmunds. This instrument condenses upon a microscopic specimen a large pencil of unrefracted light, and the image is seen upon a black foreground.

#### HEALTH OF FOREIGN CITIES.

THE Registrar-General states that a summary of the weekly returns with which he is favoured by various local authorities abroad, shows that the average annual death-rate during the first quarter of this year in thirty Indian and Foreign cities, having an aggregate population of nearly thirteen millions of persons, was equal to 32.2 per 1,000. The average rate in the twenty-two European cities was 32.7 per 1,000, against 26.1 the average rate in London, Edinburgh, and Dublin. The lowest death-rates during the quarter were 18.2 in Brooklyn and Philadelphia, 19.4 in Boston, and 19.7 in Christiania; in the other towns they ranged upwards to 41.3 in Naples, 42.8 in Alexandria, 43.3 in Buda-Pesth, 47.3 in Trieste, 56.3 in St. Petersburg, and 71.8 in Madras. The death-rate in Madras showed a further decline from the excessively high rates in recent quarters; the fatal cases of small-pox and cholera showed a considerable decline from the numbers returned in the three preceding quarters. Cholera caused 473 deaths in Calcutta, 378 in Bombay, and but 40 in Madras. Small-pox, to which but 2 and 20 deaths were referred in the two previous quarters, caused 403 deaths in

Calcutta during the first three months of this year, of which 180 were returned in the two weeks ending March 30th. Small-pox also showed increased prevalence in Bombay, St. Petersburg, Vienna, Buda-Pesth, and Trieste. In St. Petersburg, no less than 2,273 deaths were referred to typhus, enteric, and simple continued fevers, equal to a rate of 13.6 per 1,000; in London the death-rate from these forms of fever did not exceed 0.40 per 1,000. Fever was also prevalent in Paris, Amsterdam, Buda-Pesth, Turin, and Philadelphia. Measles caused 472 deaths in Bombay, 325 in Paris, and 133 in New York. In Berlin, 175 deaths resulted from scarlet fever, against 331 in the preceding quarter; 121 deaths were referred to this disease in St. Petersburg, and 326 in New York. Diphtheria was again fatally prevalent in Paris, causing 398 deaths (exclusive of 340 referred to croup), against 311 and 347 in the two previous quarters; this disease caused 260 deaths in Berlin, 315 in Vienna, 330 in New York, and 168 in St. Petersburg.

#### SANITARY AUTHORITIES' LIABILITIES.

FROM reports published, we learn that the magistrates sitting in petty sessions at Hampton, were, on Monday, engaged some hours in hearing a case of interest to sanitary authorities and to the public. Application was made to the magistrates by the Vicar of St. James's, New Hampton, to obtain payment of a sum of over £19 from the Kingston Rural Sanitary Authorities. It appeared that scarlatina was prevalent in Hampton last autumn, and complainants then took all precautions, even to disinfecting their schools voluntarily. In January of this year, when there was but one case known among the cottagers, and that imported, the trustees were required by letter from the clerk to the authority to close the school for six weeks, and to disinfect the premises. The schools were closed immediately, and the requirements carried out, upon the completion of which the medical officer said the schools need no longer be closed. The trustees then applied to the sanitary authority for reimbursement of the charges incurred in disinfecting, and also for the amount of school fees lost. The original claim was about £30, but it was reduced so as to bring the matter within the jurisdiction of petty sessions. The claim was resisted generally upon the ground of non-liability; but the magistrates made an order for the payment of the amount of school fees lost and the costs of the hearing.

### SCOTLAND.

AMONG the graduates capped at Glasgow University, last week, were five who obtained the degree of M.D., namely, W. S. Anderson, W. Findlay, J. L. Miller, J. Service, A. Hall; one M.B., W. Shaw; and one M.C., W. Arthur.

WE are requested to state that the petition to the Senatus of the Aberdeen University, published in the JOURNAL of May 4th, does not apply to the Medical Clinical examinations conducted by Dr. Smith-Shand and Dr. MacLagan of Dundee, which have given general satisfaction, but only to the Surgical Clinical examinations conducted by Dr. Pirrie and Dr. Ogilvie Will.

THE local authorities of the parishes of Dumbarton, Bonhill, and Cardross have been negotiating, through representatives, for some time back, with the view of converting the hospital at Dumbarton into a common hospital for infectious diseases under the Public Health Act, 1867. The representatives have agreed on a plan for joint occupancy; this has been forwarded to the Board of Supervision for approval.

#### MEASLES IN GLASGOW.

DR RUSSELL, Medical Officer of Glasgow, in his report submitted to the sanitary department of that city last week, states that there has been an outbreak of measles among the children of the Industrial School, Rottenrow, from which they had removed seventeen cases. The disease was attacking the town on all sides. So far it has prevailed

among the children of the wealthy and well-to-do, so that it has not yet to any great extent manifested its presence as a cause of death. Schools, the medical officer remarks, are the chief means of spreading measles; and he adds: This disease was infectious from the very outset, when sneezing, watery eyes, and other catarrhal symptoms may only indicate an ordinary cold. It was a great mistake to think measles beneath notice as an infectious disease. It may prove fatal to a child here and there in any rank of life, but to the bronchitic children of the lower, working, and middle classes it is always dangerous. The last epidemic in Glasgow was in 1871, and killed eight hundred and ninety persons. He also states that one case of small-pox was discovered—the first for six weeks. The girl was employed in a rag-store; but further than that, no hint of the probable origin of the infection had been obtained.

#### NEW SCHOOL OF PHARMACY IN EDINBURGH.

THERE was opened last week in Edinburgh, in Marshall Street, a School of Pharmacy and Chemistry, of which the object is to prepare students for the major and minor examinations of the Pharmaceutical Society. The lecturers are Mr. R. Urquhart in *Materia Medica*, Mr. T. W. Drinkwater in Chemistry, and Mr. D. McAlpine in Botany. Dr. Charles Bell commenced, in the hall of the new school, on Wednesday last, a qualifying course of lectures on Midwifery and the Diseases of Women and Children.

#### THE EDINBURGH SCHOOL OF MEDICINE.

THE summer session of the Edinburgh School of Medicine, both the University and Extra-academical classes, began on Wednesday, May 1st. In opening the University course on Medical Psychology, Dr. Grainger Stewart expressed his approval of the recommendation of the University Commissioners that there should be established a separate lectureship on insanity, and said that this would probably be the last time on which he would have to take charge of the course. He approved of the proposal of the Commissioners; 1. Because it was not possible that the Professor of the Practice of Physic could find time properly to conduct both classes; 2. Because it was not likely that in future the holder of his chair would be at the same time a great authority on mental diseases; 3. Because the subject was one of great importance, and fully deserved to have a special teacher set apart for it. Remarking upon the great power and responsibility which the State put into the hands of medical men, by permitting them in their judgment to deprive individuals of their personal liberty, he said it had always seemed to him peculiarly anomalous that the State did not at the same time require the medical man who was intrusted with such a power to know something of the nature and treatment of mental disease, as a condition necessary to obtaining his certificate.

#### ILLNESS OF PROFESSOR BALFOUR.

PROFESSOR BALFOUR was prevented by ill-health from commencing his course of botany, and the class is accordingly conducted for the present by his son Dr. I. Bayley Balfour. We are glad to hear that the Professor is rapidly recovering, and expects to be able to take charge of his class himself in a short time.

#### TRIAL OF M. CHANTRELLE.

THE trial in Edinburgh of M. Chantrelle, a teacher of French, for the murder of his wife, which is expected to prove one of unusual interest from a medico-legal point of view, commenced on Tuesday last. The accused is charged with having administered or caused to be taken by his wife, in an orange or parts thereof, or in lemonade, or in some other article of food and drink, a quantity of opium or other poison, in consequence of which she died on January 2nd. He is further charged with having exhibited malice and illwill towards her, and had many times struck and otherwise maltreated her. A *post mortem* examination was made by Professor MacLagan and Dr. Littlejohn, and a chemical analysis conducted by Professor Crum-Brown. The results obtained have not been hitherto made known. The prisoner is defended by able counsel.

## IRELAND.

A CASE of small-pox has occurred at Birr Barracks: the first for many years in that locality.

THE annual meeting of the Royal Medical Benevolent Fund Society of Ireland will be held on the 3rd proximo, the first Monday in June, in the King and Queen's College of Physicians.

AT a meeting of the Dispensary Committee of the Glencullen District, Rathdrum Union, held on the 25th ult., Dr. W. Brittain Mackay was elected medical officer, in the vacancy caused by the resignation of Dr. Croly. There were three candidates for the post, the salary of which is £110 *per annum*.

DR. P. CUTLER has been appointed to succeed the late Dr. Baldwin as Medical Officer of the Kilmeadan Dispensary District, Waterford Union. The salary attached to the post is £100, independent of fees, and has recently been reduced by £20 yearly, the district being a small one.

AT a meeting of the Limerick Board of Guardians last week, a resolution was adopted to the effect that a Common Board for the United Kingdom, for the examination of medical students, was necessary, instead of, as at present, nineteen bodies authorised to confer diplomas, each having its own standard of examination; as, under the present system, efficiency in the Poor-law Service was not always obtainable.

## HEALTH OF BELFAST.

DURING the March quarter, the annual death-rate was equal to 31 in every 1,000 inhabitants. The deaths comprise 11 from small-pox, 78 from fever, 42 from measles, 19 from scarlet fever, 11 from whooping-cough, 5 from diphtheria, and 39 from diarrhoea. The mortality from these seven zymotic diseases amount to 205, a number equal to an annual mortality of 4.5 per 1,000 of the population in 1871, or allowing for the probable increase since that period, to 4.0 per 1,000.

## ZYMOTIC DISEASES IN CORK.

IN the first quarter of the present year, the deaths in Cork from zymotic affections include measles, which caused 49 deaths; fever, 18; whooping-cough, 10; diphtheria, 1; and diarrhoea, 24. The annual death-rate was high, being equal to 34 in every 1,000.

## REFUSING TO VACCINATE.

A SHERIFF's officer, named Savage, was last week prosecuted, at the Kinsale Petty Sessions, for the eighth time, at the suit of the Poor-law Guardians, under a summons charging him with neglecting to have his child vaccinated according to the provisions of the Act. The defendant made some trivial excuse, and an order was made that the child should be vaccinated. We regret, in a case like this, that the magistrate did not inflict a fine, or even imprisonment, as an example to other offenders.

## THE MEATH HOSPITAL.

THE ceremony of the distribution of prizes on the close of the winter session took place in the theatre of this well known seat of clinical instruction last week. A large number of students were present. The prizes were awarded as follows: First Medical Prize, Mr. Thomas Lecky; Second, Mr. Armitage Forbes; First Senior Surgical Prize, Mr. Thomas H. Lingard; Second, Mr. Lucas Middleton; Junior Surgical Prize, Mr. T. W. Pike and Mr. Charles Adams. The answering for the prizes was excellent, and the competition close. For the Senior Surgical Prize, the answering was so good that the first two candidates were bracketed, each being awarded a prize of equal value. In accordance with the usual custom, addresses were delivered by the Senior Physician and the Senior Surgeon to the Hospital—Dr. Foot and Mr. Porter—on presenting the successful competitors with their prizes.

## THE SMALL-POX EPIDEMIC.

DURING the last week, there was a falling off in the number of admissions of cases of small-pox into the Dublin hospitals; but the type of the disease is reported to have increased in virulence; and this is evidenced by a considerably greater number of deaths.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE annual election of examiners in this College took place on Tuesday last. In addition to the outgoing officers, who offered themselves for re-election, Messrs. Wheeler and Robinson were also candidates. With the exception of Mr. H. G. Croly, the members of the former courts of examiners, and in addition Mr. Wheeler, were elected. The following is the official list:—Examiners to examine candidates for the letters testimonial and fellowship—Messrs. B. Wills Richardson, Edward A. Stoker, John Barker, Edward O'Grady, William H. O'Leary, William Thomson, Robert S. Swan, and William J. Wheeler. Examiners to examine candidates for the diploma in midwifery—Messrs. Henry Croly, John R. Kirkpatrick, and William J. Smyly. Examiners to examine students as to their proficiency in general education—Messrs. Frank J. Davys, Michael J. Malone, and Robert Morton. The annual election of President, Vice-President, and Council of the College will take place, according to charter, on June 3rd. Dr. Robert McDonnell, F.R.S., the present President, will be succeeded, in the ordinary course, by Dr. P. C. Smyly, now Vice-President. For the Vice-Presidency, then to be vacated, Dr. Mapother, Professor of Physiology in the College School, is, we believe, a candidate. There will probably be two, if not more, vacancies on the Council to be filled up on the same occasion. Dr. A. H. Jacob and Mr. Elliott have already, we hear, signified their intention of seeking election.

## DEATH FROM CARBOLIC ACID.

WE regret being called upon to record the death of a nurse in one of the Dublin hospitals in consequence of her taking carbolic acid in mistake for wine. It appears, from the very meagre and unsatisfactory report of the coroner's inquest that has been permitted to appear, that the deceased drank the acid from a bottle containing, as she supposed, wine. A verdict of accidental death, by misadventure, was returned. In the absence of any reported evidence as to whether the bottle was labelled or not, and as to the state in which the unfortunate woman was when induced to help herself to what, presumably, she mistook for a patient's wine, we would only remark that the carelessness of hospital authorities in general is painfully evidenced by this case. We have over and over again seen the undiluted acid, and strong solutions of it, left in unlabelled bottles in the wards of hospitals in reckless proximity with similar bottles or vessels containing medicines or stimulants. Mr. Shaw has shown (*JOURNAL*, vol. ii, 1877, p. 638), that out of a total of seventy deaths by carbolic acid poisoning he has noted, twenty were caused by taking it in mistake for medicine. When we consider that eleven of these twenty deaths occurred in hospitals and other public institutions, the responsibility that rests upon the authorities of such institutions should make itself felt. In all the deaths reported to have occurred in hospitals from this cause, it would appear that the nurses had free access to the strong acid and had mistaken it for wine or medicine. There is no reason why carbolic acid in its undiluted form should ever leave the hospital pharmacy. For no ordinary purpose is it necessary to have a stronger solution than a five per cent. one in the wards; and in the majority of cases in which the acid is employed, a much weaker solution will suffice. In our comments on the case that occurred in the Homerton Small-pox Hospital, in which a nurse caused a patient's death by giving carbolic acid in mistake (*JOURNAL*, vol. ii, 1876, p. 799), we stated that the arrangements of any hospital in which such a mistake could occur merited the severest condemnation. As we then also remarked, unless more intelligent action be taken by those who possess authoritative supervision in such matters, we must anticipate—as this case has proved—a repetition of similar accidents.

# MEDICAL REFORM: DIRECT REPRESENTATION OF THE PROFESSION IN THE GENERAL MEDICAL COUNCIL.

THE article under the above heading, in the JOURNAL of April 27th, concluded with the statement that the Association claims the representation of the profession in the General Medical Council—first, as a right; and, secondly, as a means of improving the composition and working of the Council by balancing the undue preponderance of the licensing corporations upon it. Reference was slightly made to the heavy demands on the funds of the Council—funds supplied entirely by the members of the profession, as distinct from the Universities and Corporations—by lengthy discussions, in which the interests of the Corporations were alone concerned; while the wealthy bodies who send their representatives to it, charged certainly with the duty of safeguarding their interests, contribute nothing. The care of these interests may be one explanation of the remarkable manner in which all the representatives of the Universities and Corporations in Scotland and of the Universities and Colleges in Ireland were arrayed against the conjoint scheme proposition in the late debate in the General Medical Council. Whether the fund which maintains the Council during its sittings be raised in the form of a tax or not, it is undeniable that it does not come from the Universities and Corporations, but that it is drawn from the profession. Some notion of "taxation", however, must evidently have been running through Dr. Quain's brain when he stated, at the interview of the Medical Reform Committee with the General Medical Council, that the Chairman of the Committee had "made use of a very remarkable phrase 'taxation'," when no such word had passed his lips.

The mention of the meeting between the General Medical Council and the Medical Reform Committee of the British Medical Association demands a few words. Some misapprehension having occurred as to the correspondence which led to the meeting, we are now in a position to place the facts before our readers.

The Medical Council having been called together, the Chairman of the Medical Reform Committee, acting on its behalf, wrote to Dr. Acland, the President of the Council, on March 30th, twelve days before the commencement of its session, and forwarded him the so-called Bill of the Association, together with the Reports of the Committee passed at the annual meetings at Norwich in 1874, at Sheffield in 1876, and at Manchester in 1877, with the object of bringing under the consideration of the Council the views as to medical reform advocated by the Association, so as to reconcile any existing discrepancy, which once accomplished, both the Medical Council and the Association might then unite in urging the Government to grant the prayer of the profession. On April 9th, the eve of the assembling of the Council, Dr. Waters again wrote to Dr. Acland, and expressed a hope that the opinion of the General Medical Council might be taken on the direct representation of the profession upon it. A reply was received from the Secretary of the Council, that the letter should be laid before it. The British Medical Association had placed the opinion of the Association in this matter before the General Medical Council in 1868. The late Dr. Sibson, as President of the Council of the Association, headed the deputation. Sir D. Corrigan and Dr. Andrew Wood pleaded strongly in favour of it; the late Dr. Parkes said a good case had been made out for considering whether the constitution of the Council might be improved by the introduction of a new class of members, and whether its counsels would not be thereby strengthened. He believed this would be the case, because the opinions of bodies elected by representatives were always regarded with more consideration.

Dr. Sharpey stated that the Council was pledged by its proceedings to an inquiry into its constitution, and the question of its alteration would be inevitably raised in any amended Bill. This prediction of Dr. Sharpey has been, and will again be, fulfilled. He is still of opinion that the power of the representatives of the Corporations should be diminished by the addition to the Council of members who are not office-bearers in any of the Corporations. From that day to the present, the General Medical Council, although invited even by the late Government to express an opinion on its constitution, has never suggested any modification of its composition. Far from following the example of the House of Commons, no decision as to its reform has ever been taken at its repeated meetings; and on this point the Medical Council seems to have been most unfortunately in antagonism to the profession. Two facts tend to prove this. First, in 1869, a large deputation, representing about ten thousand members of the pro-

fession, waited on the General Medical Council, and expressed their dissatisfaction with its composition. Secondly, in 1870, when the Medical Act (1858) Amendment Bill was brought down to the House of Commons, a large proportion of the profession opposed it on the ground that it did not grant representation in the General Medical Council to the profession.

It will, indeed, be strange if this prayer of the profession be disregarded in any medical Bill, was the observation of the Earl of Lichfield in the House of Lords in 1870. Who, then, are the real obstructives in regard to medical reform? Certainly not the Medical Reform Committee of the British Medical Association. As has been already stated, time upon time, the Association has advocated medical reform from the earliest period of its existence, and representation in the General Medical Council is one of its cardinal principles; the true, the persistent obstructives are those who resist this legitimate demand of the profession. Year after year since 1870, the Association has redemanded representation in the Council, and the Medical Reform Committee would be false to the trust reposed in it if it were to abandon the claim. The Committee deemed it, therefore, of vital importance that the opinion of the General Medical Council, which has undergone many changes during the last ten years, should be taken respecting it at the present crisis.

The Registrar of the General Medical Council acknowledged the receipt of Dr. Waters's letter of the 9th April thus:

"April 11th, 1878.

"Sir,—I am directed by the President of the General Medical Council to acknowledge the receipt of your letter of the 9th instant, and to say that the letter will be laid before the General Medical Council at its present meeting.—I am, sir, your obedient servant,

"W. J. C. MILLER, Registrar of the General Medical Council.

"Dr. Edward Waters."

On the 12th April, Dr. Waters wrote to the Registrar:

"Chester, April 12th, 1878.

"Sir,—I beg to acknowledge the receipt of your letter of the 11th instant. I am very happy to hear that the views of the Association will be submitted to the General Medical Council during its present meeting. I hope the Council will not negative the proposals without giving an opportunity to the Medical Reform Committee of defending them.

"The Committee will have a meeting in London on Wednesday next, and some of its members might possibly attend before twelve o'clock on that day.—I am, sir, your obedient servant,

"EDWARD WATERS.

"W. J. C. Miller, Esq., 315, Oxford Street, London, W."

On the 16th April, Dr. Waters received this reply:

"London, April 15th, 1878.

"Sir,—In answer to your letter of the 12th instant, I am directed to forward to you a copy of the resolution passed thereon this day by the General Medical Council. With a view to making the appointment for Wednesday at eleven o'clock, it is desired that you would be so good as to telegraph to me your answer as soon as possible.

"That, in reply to the letter of Dr. Waters of April 12th, the President be authorised to receive Dr. Waters and members of the Medical Reform Committee on Wednesday at eleven o'clock, in order to hear their views of the proposals referred to in the letter of Dr. Waters, and that such members of the General Medical Council as desire it shall be present at the interview.—I am, sir, your obedient servant,

"W. J. C. MILLER, Registrar.

"Dr. Waters, 14, Nicholas Street, Chester."

On the receipt of this letter, Dr. Waters sent the following telegram to the Registrar of the General Medical Council:

"Excuse succinctness of telegraphic reply. I cannot formally summon Committee to attend an informal meeting. I will, however, I hope not unaccompanied, keep the appointment made for eleven Wednesday."

Dr. Waters, at the same time, requested the Secretary of the Association to summon the members of the Medical Reform Committee to the proposed interview by telegram.

It is considered desirable, for the information of the members of the Association, thus to supplement the report of the meeting between the General Medical Council and the Medical Reform Committee, because Dr. Quain, in no measured terms, for which, however, he subsequently expressed regret, arraigned Dr. Waters as wanting in courtesy to the General Medical Council, in intimating that within a certain time on a certain day would be more convenient than another for the members of the Committee to attend. His Grace the Duke of Richmond and Gordon granted an interview of considerable length to members of the Medical Reform Committee on a particular day, to enable them to report the result on the following day to a specially convened meeting.

of the Committee, and Dr. Waters was doubtless encouraged to feel that he might expect, as was the case, similar consideration from the General Medical Council to accommodate men residing in localities far distant from the place of meeting, whose sole object in attending was to bring the General Medical Council and the Association into accord when medical legislation was impending.

The question of courtesy being settled, a still more curious question arose: Was Dr. Waters, as he represented himself, *de jure et de facto* the Chairman of the Committee; had the Committee itself any real existence? Now, as the Committee comprises the President, the President of the Council and President-elect, five ex-Presidents of the Association, six physicians to large hospitals and lecturers in important medical schools, and inasmuch as several members of the Committee so constructed, stood before the General Medical Council with their chairman and convenor before them, the glaring absurdity of this contention may be dismissed without further comment. History, however, repeats itself. When the deputation waited on the General Medical Council in 1868, as now in 1878, an attempt was also made to show that the Committee did not represent the Association; this indicates at any rate a respect for the Association.

One point more in connection with this memorable meeting. The Committee was pressed to show what they had done for medical reform since 1870. They could only reply that they had done their best—it might have been said their very best. In the session of 1871, they drafted a Bill, of which Mr. Headlam gave notice, but the introduction of rival measures by other parties deterred Mr. Headlam from proceeding with it. He said that the profession must be united to carry any such measure, embracing not only private but public interests. Acting under the advice of Mr. Headlam, which the Committee could not disregard, two sessions were thus lost. In 1873, Mr. Headlam again introduced the Bill, which was read and printed. Copies of this Bill may be obtained by all who are interested in medical reform; the cost is virtually nothing. In 1874, there was a change of government, and legislation was out of the question. Mr. Headlam, the old and valued friend of the Association, lost his seat. At this time, however, a new condition of things presented itself. The English authorities were making, under the sanction of the General Medical Council, strenuous efforts to combine for examination. The late Dr. Sibson, a long proved and influential member—now deeply regretted—of the Medical Reform Committee, was staunchly in favour of the Committee suspending action pending these efforts so as not to embarrass them. Each year it was expected that the work would be completed. It was firmly believed by Dr. Sibson that if the conjoint scheme were voluntarily completed in England, it would then follow in Scotland and Ireland. No secret was made of this modified course of action by the Committee. It was distinctly laid before the Association at the annual meeting in Norwich in 1874, and approved year after year until, at Manchester, the Committee reported they were “happy in the knowledge that their forbearance had borne good fruit, for they had to congratulate the Association on the success which had at last crowned the efforts of the Universities and Licensing Corporations of England, in establishing a conjoint board of examination for their division of the kingdom.”

Dr. Sibson, in the College of Physicians, was an active promoter of the English conjoint scheme, and he greatly influenced the Committee not to press for direct representation until the former point was settled. The forbearance of the Committee shows how earnest were their efforts not to oppose, but, on the contrary, to work with the Medical Council and with the English authorities in favour of the conjoint scheme. The Committee regarded the success as a recognition of one of the objects for which the Association had so long contended, and felt themselves thereby greatly strengthened.

In consultation with, and under the guidance of, eminent members of the House of Commons, they were actively engaged and about to act during the present session, when they were informed that the Government had a Bill prepared and ready to be brought in. During the whole period thus gone over, the Association has never given up either of the two points. It has postponed action with the object of strengthening its advocacy of the conjoint scheme, with regard to which it was certain to meet with an amount of opposition which, even one of the strongest Governments that has been known for many years has hesitated to encounter. The delay in this respect has proved an enormous advantage, and has greatly strengthened those who seek to extend the conjoint scheme to Ireland and to Scotland.

No sooner, however, was success supposed to have crowned the English authorities in their laudable efforts to combine, than a vote, little anticipated, in connection with the University of London, as regards the admission of women to its degrees, threw the whole scheme into a position of the gravest peril, and medical reform seemed

to be again relegated to an unknown period. The inability of the General Medical Council to cope with the difficulties besetting the question has been well shown during the twenty years of its existence; and, again, by its failure to agree to a basis of medical reform during its recent session, when no notice was taken of the long urged demand of the profession for direct representation, although it was placed before them by the Medical Reform Committee; and although Dr. Sharpey, so long ago as 1868, stated that the question of the alteration of the Council would be inevitably raised in any amended bill. The Council at its commencement began work on a fund raised from those already in the profession, which must have amounted to £32,000 if the number was sixteen thousand. Since then, now twenty years, the Council has also received from the profession, in five-guinea fees for registration, large sums annually. In 1874, the income of the General Medical Council was reported to amount to £6,004. The calculation of it at £5,000 a year however, would, during twenty years, give £100,000, which, added to the first £32,000, would make £132,000 paid to the Council by that profession, with respect to which it exercises judicial functions, but which is not directly represented on it. What has the Council given to the profession in return for this sum, or for whatever it may have received? Certainly not medical reform. A man may be Graduate of an University, Fellow of one or perhaps two Colleges of Physicians, Consulting Physician to a Hospital, may have been President of the British Medical Association, may have received flattering recognition from professional societies in other countries, but is none the less not deemed worthy to have a voice in the election of any one of the numerous members of the General Medical Council. It cannot be supposed that, with a knowledge of these facts, the profession will silently submit to the total eclipse of its voice. As regards the question of the conjoint scheme, the General Medical Council also failed; a division of fourteen on one side to ten on the other is not such as to carry great weight. And though the voice of the Association may have been ignored as regards direct representation, it was cited by Sir James Paget in favour of the conjoint scheme.

The objection of difficulty of election raised against direct representation is easily grappled with. The numbers of the constituency cannot be adduced against it. Dr. Humphry of Cambridge made it his pride that he was elected to the Council by all the graduates of his University. The number of that constituency ranges between five and six thousand, and yet the election has never been marked by difficulty or even excitement. If such has proved the case in that instance, no greater difficulty need be looked for as regards England with its 14,000 electors, certainly not with Ireland numbering 2,360, and Scotland with its 1,820 electors.

The Association has been reproached with not having the provisions for carrying out direct representation completed. The charge is baseless, and is a mere haphazard assertion, used either in ignorance or wilfully to mislead and to deceive.

The following is a summary of the method proposed. The registrar of each of the Branch Councils is to be sworn before the proper authorities, “that he will conduct the election and do all things relating thereto without favour or affection, and will make true returns.”

Notice of the intended election will be published in certain newspapers; and, for one month afterwards, the registrar shall receive the names of candidates, who must be registered medical practitioners, and must be duly nominated by twelve or more registered medical practitioners. As soon as may be after the expiration of the above specified month, but not less than fourteen days previous to the day appointed for the election, the registrar shall forward by post to each registered medical practitioner resident in his part of the United Kingdom, a voting paper, containing the name or names of all persons who may have been nominated as candidates, with directions that the voter shall affix his initials opposite the name or names of the candidate he may select, and shall sign each voting paper in the presence of a witness who shall attest the same, and shall then transmit it to the registrar from whom he received it. All the expenses shall be defrayed out of the funds at the disposal of the Branch Council for the division of the kingdom in which such election shall be held.

*Fifth Schedule.*—To the Medical Registrar for . . . We hereby nominate — as a fit and proper person (or fit and proper persons) to be a member (or members) of the General Medical Council, at the election to be held on the day of . . .

Signatures.	Titles.	Residences.

*Sixth Schedule.*—Voting-paper for Election of Representatives of Registered Medical Practitioners in England and [or in Ireland or Scotland, as the case may be] on the General Medical Council.

Names of Candidates.	Titles.	Residences.

I, the undersigned, being a registered medical practitioner, residing at \_\_\_\_\_, do hereby vote for the candidate [or those candidates] opposite whose name [or names] I have placed my initials. (Signature) Witness \_\_\_\_\_, N.B. Should you vote for more than \_\_\_\_\_ names in the above list, this voting-paper will be invalid. This voting-paper must be returned to me on or before the \_\_\_\_\_ day of \_\_\_\_\_, Medical Registrar for \_\_\_\_\_.

The expense of the election may be easily calculated by the amount of postage of the proxy papers. The return postage would naturally fall on the voter. The expense of the papers would be trifling compared with the postage. In England, there are about 14,260 medical men, which gives £59 8s. 4d. as postage; in Ireland, 2,360, which gives £9 16s. 8d. as postage; in Scotland, 1,820, which gives £7 11s. 8d. as postage.

### MEDICAL TEACHING IN THE UNIVERSITIES.\*

WE may take it, then, that, in all subjects up to the date of entry upon serious clinical work, the old universities can, out of funds and material at their disposal, endow chairs which would attract and retain the best teachers of the day, teachers who would work even at greater advantage than the occupants of any such chairs elsewhere. Even if students of medicine had to leave the universities at this stage, surely it were well to detain them thus far. Would it be, however, possible adequately to carry on their education beyond this point: adequately, and not in a perfunctory way, which might fail to benefit them, and might discredit the universities? It is said that the Addenbrooke and Radcliffe Hospitals, if not positively too small to contain material for teaching, are, at any rate, placed in districts where such material is less easily found. Dr. Foster qualifies this statement, and says he finds in the wards of Addenbrooke's cases numerous enough and important enough for educational purposes. We believe that at present this can be said better of Cambridge than of Oxford; for a recent visit made on our behalf to the Radcliffe wards revealed but "seven cases of surgical accidents and operations, one case of fever in the fever-ward, and most of the cases in chapel". This report has been corroborated for us by another able observer in Oxford. This seems unpromising; but we fail to see why the Radcliffe should be so different from Addenbrooke's, of which we ourselves happen to know more. In cases of severe accident, no doubt, the latter is often wanting; but, in recent years, we have always found in its wards ample material for examination purposes, and we carry our memories back twenty years or more to a time when Professor Paget taught us that inductive diagnosis of nervous diseases since developed by the school of Hughlings Jackson, and that minute investigation into blood-states which Addison initiated, and which were probably carried on in a hospital fed from a malarious country. At that date, Dr. Humphry was performing his earlier excisions of joints, and was attracting such cases to the wards, and also, by irrigation and other methods, he was pursuing those antiseptic indications lately ardently followed up by Mr. Lister. Our time within those walls was indeed too brief, but our memories are stored with vivid impressions which have been more permanent than those of a larger experience in other fields of labour. In the earlier days of study, the simple effect of a few cases well investigated and ably demonstrated is far more useful and abiding than an embarrassment of riches. A case of chronic bronchitis in the hands of a master is more valuable to a young student than half a dozen cases of pre-systolic murmur. As regards Addenbrooke's, then, we can promise ample material for third year's men, and we do not think it desirable that men should confine their studies to any one hospital. It must not be supposed that no alterations are needed in these hospitals. The Radcliffe is probably in worse care than Addenbrooke's, because it is more in the hands of local people and local subscribers.† If they are to be centres of medical teaching, they must be brought in part at least under university government, and even subsidised by the University.

The staff appointments must also be held by the members of the University, to the exclusion of local practitioners as such. Aural, ophthalmic, and dermal classes, and obstetric and children's wards, if established, would attract even more patients than could be well managed, and cases of chronic nervous disease are to be found abundantly in the district infirmaries. The County Asylum is already used as a school of mental diseases. The increasing reputation of the school, acting in part upon medical men and in part upon the public, would rapidly promote the assembly of important cases; and, as every district has its "specialty", Oxford and Cambridge, like Norwich, would prove, no doubt, to be "strong" in certain maladies. It is objected to all this that bodies attract inversely as the square of their distance, so that the nearness of the London hospitals would certainly empty the University wards of students. But, if this be simply true, every London student should be drawn from Westminster, Charing Cross, St. Mary's, and University College Hospitals to St. Bartholomew's, Guy's, and St. Thomas's. Dr. Foster points out that University College Hospital contains only one hundred and twenty beds—that is, no more than the Oxford and Cambridge Hospitals—and Dr. Payne reminds us of the eminent schools of medicine in such small towns as Heidelberg, Jena, and Göttingen. As it is, men are positively discouraged from ward study at Oxford, and not much sought for at Cambridge; but, in the new proposals of Cambridge, a prospect of the finest teaching in the world up to the end of the third year is opened out, with the added advantage to the student of living in the presence of other culture, of gaining those habits of the refined gentleman which, as Dr. Foster says, are so precious to the doctor and the doctor's patients (pp. 7-8), and, finally, of moulding himself in his first and second years in that scientific school which it has been Dr. Acland's aim to establish in Oxford, and in which he has so signally succeeded. The perfection of the sciences ancillary to medicine is the condition of all true progress in medicine itself, and to secure this indispensable condition in Oxford has been Dr. Acland's ambition and his title to the gratitude of ourselves and of our children. For this he has given more than one man's work, and has sacrificed much that is dearest to men, not time and money alone, though this is much, but even health and the rival claims of society and of home. We trust that, under his guidance, the medical school of Oxford may make some progress in its own special work. If we admit that the establishment of the science schools was a previous need, we may urge now that this finished work may be led to its practical outcome.

One disadvantage there is in the relations of the Oxford and Cambridge Schools of Medicine to those in London which has, perhaps, received even less attention than it may require: we refer to the difficulty which men passing from the former to the latter may find in securing resident appointments at the London hospitals. In our experience, this has been for many years a great misfortune to University men. It does not seem an insuperable difficulty, and we trust that an endeavour will be made to secure openings for Oxford and Cambridge students in this direction.

Another difficulty at both universities, but at Oxford more especially, is the inordinate length of time required for the course. Dr. Foster devotes much of his pamphlet to this most serious question, and makes some very important proposals to meet it. As things are, the student does not enter the university till he is nineteen years old, and does not take his tripos until the age of twenty-two. He has then to begin his medical studies, and cannot, therefore, well qualify until he reaches the age of twenty-six. This is not only a long and most expensive curriculum, but also, in Dr. Foster's opinion, it has this additional evil, that the student postpones his medical studies until, in the author's opinion, he has lost much of the flexibility of hand and brain, and fails, therefore, to attain "the medical instinct". The old usage of apprenticeship, bad and wasteful in its way, at any rate secured the early adaptation of the man to his work. It is impossible for us to quote in full the many interesting passages in which the author explains and enforces this opinion: briefly, he says (p. 6), "I assert that the most characteristic feature of a successful doctor is the possession of what, for want of a better word, I will call 'medical instinct'. I need not enter here into any psychological discussion as to the nature of this instinct, or into any justification of the use of such a term. I employ it simply to illustrate the habit of mind by which a doctor may form an absolutely correct opinion without being able to offer a satisfactory logical defence of his position, and often without having been distinctly conscious of all the individual steps which led him to the right result. If this is the case, it is clear that the special training of the doctor ought if possible to begin early in life, or at least ought not to be delayed until his nervous system has become rigid and preoccupied with unsuitable habits." In another passage Dr. Foster says, it is "the tardy assumption of professional

\* Concluded from p. 657 of last number.

† In his answer to the Committee of the Association for the Organisation of Academic Study, Dr. Tuckwell said that the Radcliffe Hospital was filled with chronic cases, sent in by right of governors' orders. We happen to know, on the contrary, that Dr. Bradbury thinks the medical cases at Addenbrooke's "are as good as in any London hospital, and the surgical good enough".

studies wherein lies the secret of the comparative professional failure of Cambridge men at the present time. . . . They work by science and logic, and are often led by apparently right reasoning to unhappy conclusions in cases where the true physician feels, as we have said, his way to the truth" (p. 11). He proposes to meet this by bringing the student to Cambridge at an earlier age, say at sixteen; and he successfully, as it seems to us, combats the more obvious objections to this change, and this not only in respect to students of medicine. We confess that we are not deeply impressed by Dr. Foster's anxiety concerning "the medical instinct". In a large experience of practitioners, we have observed that wrongheaded men are as often found among those who were put early to work as among the rest, and that among the former is a far greater proportion whose "facility" is a certain *damnosa felicitas*, a facility of "making shots", which is almost inconsistent with genuine investigation. We have ourselves far more faith in the success of patient reason and tenacious memory with *savoir faire* than in this "instinct", which, however useful in the more empirical eyes of the art, is becoming now daily less valuable and even daily a false friend. Nor do we admit that physicians from the older universities are failures; regard being had to the paucity of their numbers, and to that indifference to money-getting and to popular favour which marks men born in easy circumstances.

But we will not linger here, as we do not disagree with the author's proposal to bring lads earlier to Cambridge. He thinks the present tutelary system sufficient for younger men (and if half that is whispered abroad concerning some of our leading public schools be true, no discipline could be worse than theirs); and he points out that university discipline, which is indeed somewhat stricter in Oxford, was designed in days when undergraduates came up much earlier in life.

We may add that the foundation of Cavendish College for younger students will encourage earlier entries, as will also the admission of "unattached" students, though we are far from advising any parent to send up his son as an "unattached". An unattached student, generally, fails to associate himself with the liberal and social life of the place, and so fails to gain the urbanity which Dr. Foster desires to see in all physicians, so that if his expenses be less, the less also are his advantages. It may be urged that this early admission of students would tend to discourage mature culture in the humanities, and we should be among the first to regret this. We have said that the old universities should aim especially at the training of consultants, and in these we should encourage a training far wider than that of their profession alone. But we question the gain of keeping lads at school three years after the age when the average schoolboy has, or ought to have, learned all that is needed for his "little go". We believe that boys of seventeen to twenty would make far better progress at the university than at a public school. Moreover, an earlier call to the university would stimulate the teaching of average boys in the lower forms which, in most public schools, is very defective. The best men will take classical or mathematical honours as they do now, and the majority will graduate in the science schools which, as Mr. Huxley says, are no longer a back door by which men may secure a degree. The cause of later entries at the universities is well known to be the competition for exhibitions and open scholarships, in which older students have a great advantage. Dr. Foster does not see how this tendency is to be counteracted. We can only suggest to the Colleges—to Caius in particular, and also to that noble foundation of which he is himself so distinguished an ornament—to offer scholarships for medical students with a lower limit of age. We know that the Professors of Medicine, of Anatomy, and of Pathology at Cambridge are at one with Dr. Foster in regretting the late entry of medical students. The M.B. "might be used to denote not men of unusual ability, but men qualified to practise, and who had enjoyed the advantages of an university career" (p. 29) . . . "while after two or more 'Wanderjahre', a general or special examination should preface the M.D.—an examination searching, and, above all things, practical. The title of M.D. should not be a natural sequence of the M.B., but one of real distinction (such as the F.R.C.S.), only to be gained by men who have devoted themselves with vigour to the study of the profession" (p. 30). "It is in the production of such men that the Medical School of Cambridge ought to look for its *ratio existendi*" (p. 29).

Here are we compelled to end our survey of this pamphlet, and of the vital question which it raises. There are many passages marked for extraction which we must pass over, and many interesting side issues which we must leave for the future; among them being the suggestion that the old universities are the proper seat for certain professorships in more abstract subjects connected with hygiene, pharmacology, toxicology, medical jurisprudence, and the like. The need of such posts for men who are willing to devote their whole time to the theoretical as distinguished from the practical study of disease; the

tendency of enthusiasm to flag when the teacher knows he is but laying foundations on which some one else will build; the want of filial feeling of pupils towards the medical schools at Cambridge and Oxford, and its reasons; the pregnant suggestion that parish medical officers might be associated with the clinical teaching, taking students to aid them in out-door relief, by which the poor would also be gainers; the overloading of medical teaching with pure science—Mr. Coutts Trotter's new scheme of examinations—all these, and many other most important matters, are argued or glanced at in this pamphlet. To it we have not ventured to apply the terms of ordinary laudation; we trust, rather, that in the long articles we have devoted to it we have done what is more useful to the public, more helpful to the universities, and more grateful to the distinguished author himself.

### MEDICAL TEACHING IN CAMBRIDGE.

A MEETING of the Senate of the University of Cambridge was held on Tuesday last, May 7th, for the purpose of discussing a report of the Studies Syndicate. The Vice-Chancellor presided, and, in introducing the report, invited discussion in the first place on the recommendations as to medical studies.

Professor PAGET was of opinion that the question put to the Board of Medical Studies by the Studies Syndicate was not happily worded. It was in these words, "Whether it is desirable to attempt to found a complete medical school in Cambridge, so as to make it possible for a student to complete his whole medical course here", or whether it is "better for all concerned, while making the teaching at Cambridge as perfect as possible in the scientific subjects which are the basis of medicine, to leave students to carry on elsewhere the greater part of their clinical studies, and most of what relates directly to the practice of medicine". He objected to the alternative method of putting the question, as he thought it might create a bias among those who would have hereafter to decide as to the adoption of the report. Such a way of stating the case would be apt to mislead persons not familiar with the working of a medical school. He, also, even at the risk of being hypercritical, objected to the phrase "attempt to found". A member of the Senate, unacquainted with the working of medical schools, might think the object unattainable; but it was quite certain a complete medical school could be established at Cambridge, although the further question remained whether or not it was desirable. Dr. Paget discussed the expediency of affording complete instruction to medical students at Cambridge at considerable length, maintaining that the *onus probandi* rested on those who maintained that the University was wrong in desiring to provide the necessary instruction. He maintained that there was not an University in the whole world that did not provide instruction in subjects it compelled its students to acquire, but the medical students at Cambridge were compelled to go elsewhere to attain the knowledge which the University had laid down as essential before allowing them to take a medical degree. Such an anomaly ought not to exist.

Professor HUMPHRY said he should for some reasons be glad to see a complete medical school established at Cambridge, and if one were founded he would support it to the best of his power. He, however, had not signed the report of the Board of Medical Studies, on the broad ground that he did not consider it advantageous to the students that they should be able to complete their medical education at Cambridge. His own feeling was that the University could provide adequate instruction in the earlier study of the science of medicine—for instance, in chemistry, anatomy, and physiology, and that students would be well grounded at the University in those subjects; but he did not agree that any real good would ensue if steps were taken to enable a student to complete his medical education. He did not wish to undervalue the opportunities for clinical instruction afforded in Addenbrooke's Hospital, but he did not think they were sufficiently great or strong to render it desirable to induce students to complete their course at that hospital. He would compel students to study the other parts of their profession elsewhere. He felt sure the attempt to found a complete medical school would result in failure. He would not recommend any one to enter at Cambridge with a view of commencing and completing his medical studies there. He concluded by expressing his regret that he stood alone in his opposition among the members of the medical faculty at Cambridge to the report.

Professor LATHAM said that no one would ever advise a student to complete his education at one school of medicine; but he maintained that the University ought to provide a complete medical school, or else dispense with some of its teaching power. If they were only to educate up to a certain point, the duties of the Downing Professor would be obliterated. A complete school of medicine could be ob-

tained at a small outlay. Nor would the teaching necessarily be confined to medical students. The instruction in sanitary science might with advantage be attended by future vicars and rectors, who would be benefited by being acquainted with the means of dealing with preventable diseases. The lectures on medical jurisprudence might with advantage be attended by law students. He maintained that Addenbrooke's Hospital afforded as complete opportunities for clinical instruction as the larger hospitals, and it was not so crowded with students, which was a great advantage. He urged that there could be no doubt that the University would be doing right in completing its medical school, and the advantage of a junction of practical with theoretical teaching would soon be apparent in the increase of the number of medical students.

Dr. BRADLEY saw no difficulties in obtaining a complete medical school at Cambridge. He expatiated on the advantages for the purposes of study a small hospital had as compared with a larger institution. He objected, however, to the proposal that the Professor of Pathology should not be allowed to practise, as no London school imposed a similar restriction.

Mr. COUTTS TROTTER (Trinity) did not think it desirable that a medical education should be completed at Cambridge or any other medical school; but if at Cambridge they only promoted the study of subjects necessary for the first M.B. examination, they had more teaching power than they required. If pathology were to be studied, it must be by students of medicine who had commenced clinical work. He did not apprehend that there would be a great class, but he thought the presence of advanced students would encourage the junior students and be beneficial. He supported the report.

Professor PAGET, in reply, said he recollected when the number of medical students was very insignificant; at the present time, there were at least one hundred in the University. One reason for the increase was the increase of teaching power. As to the facilities for instruction, he urged that Cambridge possessed them in a far greater degree than Heidelberg or Göttingen. Foreigners were amazed that the old Universities did not foster their schools of medicine. The study was actually discouraged, and certain fellowships, formerly given for medicine, were diverted, under the name of reform, to other uses. He urged the completion of the medical school, not as a favour to the medical faculty, but as a matter of justice and common sense.

## CORRESPONDENCE.

### NAVAL MEDICAL SERVICE.

SIR,—The medical officers of the services will cordially agree with the remarks which appear in your impression of last Saturday. They recognise, in common with others, the obligation due to their country in a crisis like the present; but, on the other hand, if their services are indispensable, they feel that these services should be suitably recognised, and they are not so at present. A circular is placed in the hands of the junior members of the profession, with a view of inducing them to join, where, *inter alia*, it is stated that cabin accommodation on board Her Majesty's ships is allotted according to relative rank. This, on the part of the Admiralty, admits at least the fairness and justice of such an arrangement; but is it carried out? No; it is not. The Fleet-Surgeon, ranking with a Commander, is invariably relegated to a dark cabin between-decks; while the Chaplain, Paymaster, and Commander are accommodated on the deck above, where space, fresh air, and light can be enjoyed. We do not object to take choice of these cabins with other officers of corresponding rank; but we consider it a most unfair regulation, and one which must be strenuously resisted, that at no period of a medical officer's service afloat is he ever to enjoy an equal advantage with others in this respect. Let the Admiralty endeavour to act justly, and they will then not be reduced to appeal to the patriotic feelings of the profession, at a crisis like the present, to come forward and rescue them from their present position.—I am, sir, yours, etc., X.

### CONSULTANTS' PROFESSIONAL ETIQUETTE.

SIR, Your correspondent "M.B.Lond. and F.R.C.S." complains of the conduct of consultants, who, when a patient comes independently, do not mention the name of his regular medical attendant, prescribe treatment without communication with the latter.

My own experience, which is not singular, indicates, I believe, the real source of this practice. I have been not unfrequently consulted by patients under the circumstances mentioned. I find that the patient very rarely mentions spontaneously the name of his regular attendant. I began by resolving always to adopt the line of conduct your correspondent desires. Whenever a patient had been recently under treatment, often when he had not, I obtained, sometimes only by pressure, the name of his attendant, and wrote to him my opinion and the particulars of the treatment suggested. Most of the cases I see are chronic, requiring treatment for a long time; and I, in my inexperience, imagined that if I adopted this course, the practitioner would appreciate my concern for his interest, and take care that, after a time, the patient should see me again regarding further changes in the treatment—as certainly would have been the case had I followed the course of separate treatment which the patients in most cases desire. In not one single instance did I ever see the case again. My behaviour, of course, left the practitioner master of the situation, and the result showed the use he made of his opportunity. All know how easy and how common it is to run down a consultant of the patient's own choice. So I have changed my plan. I never encourage patients, under the circumstances, to come to me again; but I take no trouble about the interest of the practitioners, who do not, where they might, acknowledge practically my concern for their interests.

This is the custom of which the practitioners complain. I cannot doubt that, with many others, it has arisen from an experience similar to my own. Certainly no one ever began with a greater desire to act with scrupulous concern for the professional interest of the regular attendant of the patient.

If I put together the complaints of your correspondents and my own experience, I am driven to the conclusion that what the practitioners desire is a "one-sided reciprocity"—a thing which neither they nor any other persons are likely, as a general system, to obtain. Let them treat the consultant as they wish to be treated themselves, and I believe they would have little cause for complaint.

I am, sir, yours, etc.,

A CONSULTANT.

SIR,—Having occasion very often to invoke the aid of consultants, may I be permitted to bear testimony to the promptness and kindness which I have invariably experienced at the hands of those consulting members of our profession in London, both in medicine and in surgery, whose skilful and experienced advice has been sought by me?

With one exception, in which case quackery and not science seems to be the *modus medendi*, even when the patient has gone to the consultant unknown to me, I have never found so much as an attempt to take the patient from me. I, therefore, have nothing in common with those of your correspondents who have been complaining of unfair treatment by consultants, and cannot help feeling that many of these complaints are unfounded, for the simple reason that patients often conceal the fact, when they consult medical men, that they are under the care of any other practitioner. In one or two cases, when called in, I have been informed that the patient had not been attended by any qualified medical man; and yet, to my intense disgust, I afterwards discovered I had unconsciously supplanted a medical brother, whose services had been dispensed with merely from whim, caprice, or impatience. If such a *contretemps* occur to a general practitioner, with a tolerably fair acquaintance with the residents in the locality in which he practises, how much more likely would it be for the consultant to be deceived, seeing he usually knows little or nothing about the most of the persons who go to him for advice!

Having been, as one busily engaged in general practice, the recipient of much courtesy and true professional amenity from many of the consulting members of our profession in this city, I feel bound, in the present discussion, to give feeble expression to my indebtedness and thanks.—I am, sir, your obedient servant,

London, May 4th, 1878.

NORMAN KERR, M.D.

## ASSOCIATION INTELLIGENCE.

### NORTH OF IRELAND BRANCH.

A MEETING of this Branch will be held on Friday, the 17th instant, at 12 o'clock, noon, in the Board Room, Belfast Royal Hospital.

The President will deliver an address.

Members to represent the Branch in the Council of the Association for the ensuing year will be elected.

The Bill for the Amendment of the Medical Act, now before Parliament, will be considered.

JOHN MOORE, M.D., *Honorary Secretary*.

Belfast, May 7th, 1878.

### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETINGS.

THE annual meeting of this District will take place in the Library of the County Hospital, Canterbury, on May 16th, at 1.30 P.M.: P. B. HALLOWES, Esq., F.R.C.S., of Canterbury, in the Chair.

At 2.30 P.M., immediately after the meeting, it is proposed to pay a visit of inspection to the County Hospital at Chatham.

Dinner will be provided at the Fleur-de-Lis Hotel at Five o'clock.

WM. KNIGHT TREVES, F.R.C.S., *Honorary Secretary*.

Margate, May 6th, 1878.

### METROPOLITAN COUNTIES BRANCH.

A SPECIAL General Meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesday, May 15th, at 4 P.M.

1. To receive and (if thought proper) to adopt an amended code of By-laws for the Branch.

3. To consider the Bills for the Amendment of the Medical Act (1858) now before Parliament.

An Ordinary Meeting of the Branch will be held at the same place on Wednesday, May 22nd, at 8 P.M., when papers on Vaccination will be read by Dr. E. C. Seaton and Dr. J. Greene of Birmingham.

ALEXANDER HENRY, M.D. } *Honorary Secretaries*.  
W. CHAPMAN GRIGG, M.D. }

57, Doughty Street, W.C., May 2nd, 1878.

### SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

THE next meeting of the above District will be held at Lewes, on Friday, May 24th, at 3.30 P.M.: N. P. BLAKER, Esq., of Brighton, in the Chair.

Dinner will be provided at 5.30 P.M.

Notice of intended communications is requested by the Secretary on or before Wednesday, the 14th instant, in order that they may be inserted in the usual circular.

THOMAS TROLLOPE, M.D., *Honorary Secretary*.

9, Maze Hill, St. Leonard's-on-Sea, May 7th, 1878.

### STAFFORDSHIRE BRANCH.

THE third ordinary meeting of the Session will be held at the Mines' Drainage Office, 22, Darlington Street, Wolverhampton, on Thursday, May 30th, at 3 o'clock P.M.

VINCENT JACKSON, } *Honorary Secretaries*.  
J. G. U. WEST, }

Wolverhampton, May 5th, 1878.

### BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE fifth ordinary meeting of the session was held at the York House, Bath, on Thursday evening, April 25th; H. MARSHALL, M.D., President, in the chair. There were also present thirty members.

*New Members*.—Surgeon-General Bowen of Ridgway, and R. W. Thomas, Esq., of Keynsham, were duly elected members of the Association and of the Branch.

*Papers*.—1. Dr. E. M. SKERRITT read a paper on Cases illustrating the Treatment of Pleuritic Effusion, on which Dr. Brittan and Dr. Hensley made remarks, and Dr. Skerritt replied in favour of antiseptic treatment.

2. Dr. A. E. A. LAWRENCE read a paper on Certain Forms of Non-puerperal Uterine Haemorrhage; and Dr. Swayne replied.

*Letters*.—The PRESIDENT read letters from the Harvey Tercentenary Committee and the Nottingham Medical Defence Association; and the Secretary (Mr. Fowler) undertook to receive subscriptions for each object.

*Habitual Drunkards Committee*.—Mr. Fowler was delegated to represent the Branch on the Habitual Drunkards Bill Committee.

**VACCINATION**.—Mr. H. J. Kendrick Vines has received a Government grant of £11:5 for successful vaccination in the Littlehampton District of the East Preston Union. This is the second grant which Mr. Vines has received.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### DARLINGTON RURAL SANITARY AUTHORITY.

THE first meeting of the Guardians constituting the Rural Sanitary Authority of the Darlington Union was held on April 27th. For the fifth time, Dr. Eastwood of Dinsdale Park was unanimously elected Chairman for the ensuing year; and his services to the Authority, especially as a professional man, were cordially acknowledged.

### THE CHARGE OF PAUPERS SUFFERING FROM INFECTIOUS DISEASES.

SIR,—Observing in your JOURNAL of the 13th April that the Local Government Board have called upon the guardians of the poor in Dublin to find hospital accommodation for paupers suffering from small-pox, permit me to inquire whether it is incumbent on the sanitary authority or the guardians to take charge of such patients in England? The Public Health Act (1875) does not, I believe, extend to Dublin, and it is a question of great importance whether it rests with the sanitary authority or the guardians to take charge of the cases referred to above. The sanitary authority are expected to take charge of those above the pauper class, and to charge for maintenance, etc. (see Clause 132, Public Health Act, 1875), but such patients could not be placed among paupers. It would be necessary to find other accommodation for the latter; and as they are strictly under the care of the guardians, provision should be made by the guardians, and power given to all district medical officers to send their patients to their hospital. It is not necessary that the hospital for paupers suffering from infectious disease should be in close proximity to a poorhouse, but in some central part of a town or rural district.—Your obedient servant,  
M. O. H.

## MILITARY AND NAVAL MEDICAL SERVICES.

### MILITIA MEDICAL SERVICE.

SIR,—Having heard much of late concerning the maladministration of Army Medical Service, will you kindly permit me to give an example of the manner in which the Militia Medical Service is regulated? I joined my regiment as surgeon upwards of twenty-three years ago, during which time we were twice embodied, comprising nearly five years. I have always superintended or done the duties connected with my department. I was never absent from training, and of late years without an assistant, having seen three out, as well as two adjutants. Soon after the termination of the first embodiment, I was required to reside at head-quarters, which necessitated the giving up of a good house and farm in the country at some distance from head-quarters. Up to May 1873, I was required to accompany the adjutant through the country for the purpose of examining recruits, averaging about three days per week. After that time, I was ordered to be confined to a radius of fifteen miles from head-quarters. In March 1876, I was ordered to cease going out with the adjutant for examination of recruits; duties to be done by civilian medical practitioners. In January 1877, I was ordered to discontinue the examination of recruits at head-quarters, to be done in future by an army medical officer in garrison, and no depot centre yet formed in this district. The recruits of my regiment are now undergoing preliminary drill, the medical duties of which have invariably been conducted by the surgeon. This year, under a new regulation, an army medical officer is ordered to act, and this in addition to his onerous duties in a large garrison. I am now reduced to attendance on the staff of the regiment, with the liberal allowance of 2d. a head per week—medicine, appliances, and car-hire included, and also going out for twenty-eight days' training to a camp, at much inconvenience and a considerable distance from head-quarters. I cannot, therefore, discover what inducement there is for a surgeon to remain in this service when deprived of almost all duties and consequent emoluments, fasts being broken, notwithstanding being appointed under Royal Warrant, being secured for a lengthened period, the greater part taken up by regimental duties, including almost daily attendance at orderly-room, when not out on duty in the country, to the detriment of private practice, and denied compensation on retirement, as almost all public departments are in the habit of granting.—I am, etc.,  
MILITIA SURGEON.

### THE ARMY MEDICAL DEPARTMENT.

SIR,—It is anything but clear to me that the discontent in the Army Medical Department at present turns upon the question of unification and regimentalism. I am inclined to think either system might be made popular. For my own part, I would rather have unification with exchanges allowed than the regimental system with them prohibited, and I would rather have the regimental system with exchanges allowed than unification with them prohibited. The prohibition of exchanges, only six months' sick leave, and then half pay if it is well enough to serve, the difficulty of getting ordinary leave, etc., have, I am inclined to think, much more to do with the present discontent than the mere separating of medical officers from regiments. If the authorities had stopped at the separation of medical officers from regiments, and not brought in all kinds of restrictions in connection with unification, I think the medical officers might have been a comparatively contented body of men, notwithstanding the harshness of the manner in which we were turned out of our regiments. They might also have compensated us in money. What on earth the prohibition of exchanges had to do with unification I cannot imagine; and yet no sooner was unification carried out than this vexatious restriction was instituted.

I hope you will publish this, as I am half afraid the question is being tried on false issues.—Yours, etc.,  
SURGEON-MAJOR.

## MEDICO-PARLIAMENTARY.

*HOUSE OF COMMONS.—Tuesday, May 7th, 1878.*

*Food and Drugs Act.*—Mr. A. MOORE asked the Chief Secretary for Ireland what steps, if any, have been taken by the Irish Government to put in force the provisions of the Food and Drugs Act, 1875, relating to the detection of adulterated liquor.—Mr. J. LOWTHER said that in 1875 and 1876 the Local Government Board in Ireland addressed a circular letter to each urban and rural sanitary authority, drawing their attention to the provisions of the Act to which the Honourable member referred, and making suggestions as to its administration. In 1877, the Irish Government issued a circular informing the local authorities that police constables were authorised to assist them in carrying out the provisions of the Act. By the thirteenth section of the Act, one of the duties of the officer appointed under it related to the detection of adulterated liquor. In the case of any dispute arising, he had directed that another circular should be prepared and issued.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of Examiners, on May 2nd; and, when eligible, will be admitted to the pass-examination.

Messrs. Charles R. Tyrrell and Joseph H. H. Lawrence, students of the Middlesex Hospital; Charles A. Whitehead and Richard A. Billial, of King's College; Richard G. Cooper and Owen Pirchard, of St. Bartholomew's Hospital; John R. Rolston, of Guy's Hospital; Herbert C. Hallows, of St. George's Hospital; Walter Pearce, of St. Mary's Hospital; and Henry R. Evans, of St. Thomas's Hospital.

Fourteen candidates were rejected.

The following gentlemen passed on May 3rd.

Messrs. James F. D. Willoughby, Edward Daly, and Henry H. Taylor, of St. George's Hospital; Herbert C. Male, Robert W. Mead, and Benjamin Wainwright, of the Edinburgh School; N. E. Johnson Gaylor and Arthur S. Stokes, of Guy's Hospital; Arthur B. Carpenter and Henry N. Holberton, of St. Thomas's Hospital; William Chanley, M.D. Cantab., of University College; Thomas E. Noding and Robert E. G. Cuffie, of St. Mary's Hospital; John L. B. Oakley, of St. Bartholomew's Hospital; and Walter Johnson, of King's College.

Ten candidates were rejected, making a total of seventy-five out of the one hundred and sixty-eight examined.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 25th, 1878.

Barnes, James John Frederick, 83, Coversham Road, N.W.  
Coombs, Samuel Wellesley, Worcester  
Morton, Augustus Charles, Aylsham, Norfolk  
Shepherd, Thomas William, Ilminster

The following gentlemen also on the same day passed their primary professional examination.

Davies, Evan Naunton, Guy's Hospital  
Greensill, James Haynes, Middlesex Hospital  
Greensill, Joseph Moon, Middlesex Hospital  
Ladell, William John Simpson, St. Bartholomew's Hospital  
Leadbeater, Thomas Edward, London Hospital  
Womersley, Joshua King, Guy's Hospital

At the Preliminary Examination in Arts, held at the Hall of the Society, on the 26th and 27th of April, 1878, 76 candidates presented themselves; of whom, 24 were rejected, and the following 52 passed, and received certificates of proficiency in general education—viz., in the First Class, in order of merit:

1. H. C. L. Cooper; 2. W. W. Elver; 3. Rowland Hill, A. Mitten, and W. H. Moore; 4. H. L. Bateman and Anne McGill.

In the Second Class, in alphabetical order:

S. Aspinall, J. C. Bates, H. S. Baumgartner, J. B. Berry, B. Blackmore, R. E. Bowen, J. F. Browning, L. H. Brown, H. M. Bullock, T. E. Butler, F. G. Canell, F. M. Coppin, C. Conlan, C. E. Day, F. H. Douglas, J. H. Drury, C. H. East, A. J. Gardner, W. E. Gardiner, A. E. Garrett, W. H. Gimblett, A. J. Grant, H. S. Greenwood, G. F. Hirsch, W. Hern, H. T. Herring, G. Hessenauer, A. J. Marsack, L. B. Norris, H. S. Parkinson, A. Sales, P. M. Seathoff, J. S. W. L. Sharman, A. Shearman, A. F. Smith, E. T. Smith, F. W. S. Stone, R. W. Stratham, A. E. Taylor, H. H. Taylor, S. R. Thomas, A. G. Webster, G. D. Wendham, A. E. Woodforde, and G. A. H. Woodrce.

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 2nd, 1878.

Lucas, Charles, Dunwell, Cambridgeshire  
Pojer, Herbert Francis Montagu, West Malling, Kent  
William, Hugh Harreis, Haverdwest

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the usual monthly examination meetings of the College, held on Tuesday, Wednesday, and Thursday, April 9th, 10th, and 11th, 1878, the following candidates were successful.—For the Licence to practise Medicine: previous examination.

O'Meara, John Brett Johnston

Shove, Edith

Final examination.

Cameron, James Chalmers  
Gruggen, William

O'Neill, Edward Daniel  
Young, Alfred Naason

For the Licence to practise Midwifery.

Cameron, James Chalmers  
Gruggen, William

Moullin, James Alfred Mansell  
Weiss, Hubert Foveaux

## MEDICAL VACANCIES.

The following vacancies are announced:—

**BELGRAVE HOSPITAL FOR CHILDREN**—House-Surgeon. Applications to be made on or before the 13th instant.

**BIRMINGHAM**, Parish of—District Medical Officer. Salary, £175 per annum, and fees. Applications to the Clerk to the Guardians on or before the 14th inst.

**GLOUCESTER GENERAL INFIRMARY**—Surgeon and Assistant-Surgeon. Applications to be made on or before the 30th instant.

**HOSPITAL FOR SICK CHILDREN**, Great Ormond Street—Assistant-Surgeon. Applications to be made on or before the 16th instant.

**KENT and CANTERBURY HOSPITAL**—Physician. Applications to be made on or before June 28th.

**LEITH HOSPITAL**—House-Surgeon and Assistant-Surgeon. Salaries, £70 and £60 respectively, with board. Applications to be made on or before the 15th instant.

**METROPOLITAN FREE HOSPITAL**, Commercial Street, E.—Two House-Surgeons.

**MITFORD and LAUNDITCH UNION**—Medical Officer and Public Vaccinator for the Frarsham District. Salary, £55 per annum, and fees. Applications to be made on or before the 10th instant.

**ROYAL HANTS COUNTY HOSPITAL**, Winchester—House-Surgeon and Secretary. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 27th instant.

**ROYAL HOSPITAL OF BETHLEHEM**—Resident Physician and Medical Superintendent. Salary, £700 per annum, and furnished apartments. Applications to be made on or before the 16th instant.

**ST. MARY'S HOSPITAL**, Manchester—Medical Officer. Salary, £80 per annum, with board and residence. Applications to be made on or before the 17th inst.

**SCARBOROUGH DISPENSARY and ACCIDENT HOSPITAL**—House-Surgeon and Secretary. Salary, £120 per annum. Applications to be made on or before the 30th instant.

**SOMERSET COUNTY LUNATIC ASYLUM**—Assistant Medical Officer. Salary, £100 per annum, with board, residence, and washing.

**STOCKPORT INFIRMARY**—Assistant House-Surgeon. Salary, £60 per annum, with board and apartments. Applications to be made on or before the 20th instant.

**STROUD GENERAL HOSPITAL**—House-Surgeon. Salary, £60 per annum, with board, furnished rooms, and washing, and £30 per annum in lieu of stimulants. Applications to be made on or before the 15th instant.

**VICTORIA HOSPITAL FOR CHILDREN**, Chelsea—House-Surgeon. Salary, £50 per annum, with board and lodging. Applications to be made on or before the 18th instant.

**WILTS COUNTY LUNATIC ASYLUM**—Assistant Medical Officer. Salary, £110 per annum, with board, lodging, attendance, and washing. Applications to be made on or before the 15th instant.

## MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

**HAYWARD, T. E.**, M.R.C.S.Eng., appointed Resident Medical Officer to the East London Hospital for Children, *vice* F. H. Spooner, M.R.C.S.Eng., resigned.

**IRWIN, John Arthur**, M.A., M.D., and **SMITH, Robert M.**, B.A., M.B., appointed Honorary Physicians to the Manchester Southern Hospital for Diseases of Women and Children, *vice* J. Roberts, M.D., and R. B. Smart, Esq., resigned.

**DONATION.**—The Merchant Taylors' Company have made a fourth grant of Thirty Guineas in aid of the funds of the National Hospital for Consumption and Diseases of the Chest at Ventnor.

The Bridgwater Guardians and Rural Sanitary Authority have entered into a contract for the erection of an Infirmary for infectious and contagious cases for £670.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND; ARTS EXAMINATIONS.**—At the recent preliminary examination for the diplomas of Fellowship and Membership of the Royal College of Surgeons, 338 candidates presented themselves, viz., 96 for the first named distinction and 242 for the membership. Of the 96 candidates, 52 were successful; 22 failed to reach the required standard for the fellowship, but obtained sufficient marks for the membership; 14 had not completed all the required subjects, and 8 were rejected. Of the 242 candidates for the membership, 137 were approved, and 105 were rejected. Those who passed can at once commence their professional studies.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**TUESDAY.**—Royal Medical and Chirurgical Society, 8.30 P.M. Mr. P. Kidd, "On the Pathology of Hæmophilia"; Dr. Reginald Thompson, "On the Pathological Traces of Pulmonary Hæmorrhage"; Dr. Gowers, "The Brain in Congenital absence of One Hand"; Dr. Topham, "Abscess within Thorax, accompanied by Pulsation".

**WEDNESDAY.**—Association of Surgeons Practising Dental Surgery, 8.30 P.M. Mr. Gaine, "On some forms of Trismus arising from Dental Irritation".

**THURSDAY.**—Harveian Society of London, 8.30 P.M. Dr. Hughlings Jackson, "On a large Tumour of the Left Cerebral Hemisphere"; Mr. Lister, "On the Effects of Position upon Local Circulation".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

## PROPOSED REGISTRATION OF FOREIGNERS WITHOUT DIPLOMAS.

**SIR.**—In reference to the subject of my letter in the *JOURNAL* of April 18th, I observe that on the fifth day of the session of the General Medical Council, when Clause 8 of the Bill came under consideration, Dr. Haldane very properly pointed out that in it no mention was made of either examination or diploma. Mr. Simon thereupon "explained that this clause was only designed to meet very exceptional individual and personal cases, of the merits of which the Council would be the judges". I think, sir, that some more satisfactory explanation should be given than this. What possible "exceptional individual and personal cases" can there be in which foreigners not possessing any diplomas can have any claim to be entered on the *Medical Register* of this country? It would really seem as if the Council were seeking for the power to register some unqualified foreign practitioner whose "individual and personal case" commends itself to them. It is such the case, it is a monstrous thing, and cannot be too strongly opposed. I hope the Medical Reform Committee of the Association will take it up. The matter may seem a trivial one, but it is really one of principle, and it cannot be just that power should be given to the Council to register a man because he is a foreigner, who could not claim registration if he were an Englishman. Any properly qualified foreigner is already amply provided for by Clauses 6 and 7; and therefore I think the profession should unanimously demand that Clause 8 be expunged. The Council should have no power to register any unqualified person, whether a Briton or a foreigner, as such power strikes at the very root of the principle of the Medical Acts.—I remain, yours, etc.,  
W. DOUGLAS HEMMING.  
36, Ladbroke Road, W., April 24th, 1878.

**DR. HARRIS.**—There will be three vacancies declared in the Council of the College of Surgeons in July next, caused by the retirement, in the prescribed order, of Messrs. H. Lee, B. W. Holt, and Erasmus Wilson, who are eligible for re-election. Mr. E. Lund of Manchester, Sir H. Thompson, and Mr. John Gay of London, are the only candidates whose names have reached us.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

## MUSCÆ VOLITANTES.

**SIR.**—The optical shadows produced by the peculiar bodies to which the name of "muscæ volitantes" has been applied have been long recognised and frequently described; but there is still considerable obscurity attached to the history, *habitus*, and pathological propensities of their material archetype, and a few original observations may probably be an acceptable contribution to your *JOURNAL*, and a timely addendum to the investigations of the anxious "Inquirer" in a late issue thereof. Muscæ volitantes are usually first observed between the twentieth and thirtieth year, and begin as a faint but circumscribed blotch floating over the axis of vision at a short and uniform distance, which gradually enlarges, deepens, and finally assumes a pale amber tint, with traces of organisation, and possess a tenure of existence which is truly remarkable. One and the same musca has been observed and studied by the same individual already for a period of twenty-one years, and has certainly undergone no perceptible change for many years. The true muscæ occur in subjects whose eyes and venous system generally are in a state of capillary turbulence, and who have, recently or remotely, had recurring attacks of catarrho-rheumatic ophthalmia, in a subdued or subacute phase, and with implication of the iris, and who have, moreover, subjected their eyes to a severe and protracted strain in heavy reading, or in fine artistic details; and they invade both eyes equally. As remarked by Mr. Greenwood, the eyes are watery from turbulence of the vascular rete in the lacrymal canals; the eyeballs are, or have been, tender to the touch; the interior of the eye is over-sensitive to light, and the pupil a little irregular, whilst the sight is strong, penetrating, perfect in adaptation to distance, and quite up to par in its retentiveness of these qualities. True muscæ never spontaneously disappear, and their clinical associates are rheumatism, chronic bronchitis, and emphysema, either with or without obstructive cardiac and renal disease. In shape they may be punctate, circular, linear, crescentic, or hemispherical, and their limiting edges may be abrupt, jagged, or dendritic. Some appear with a nucleus, like a complicated knot of ribbon, and have an elongated lashing tail. In the linear ones may be observed a distinct limiting line, within which on each side is a glassy peripheral portion inclosing a central axis of overlapping and apparently tinted nucleated cells. The crescentic and hemispherical ones are fixed; the others move with the eyes upwards, downwards, and to either side, and with a rapidity proportionate to that of the eye itself. When the eyes are directed upwards, the muscæ appear to rapidly rise, not simultaneously, but in sequence, and to less rapidly subside; and if the eyes be fixed horizontally or thereabout, the muscæ leave the field of vision free till the next movement causes them to sink in their medium, whilst their shadow rises again as before. When the axis of vision is vertically upwards or downwards, the muscæ float over and trouble its area, especially in strong light; and in foggy weather they are also very annoying, though it is encouraging to know that eyes full of muscæ may, from sheer habit, become so reconciled to the inevitable as to cease to notice them, and to be sensible to their existence only under conditions favourable to their illumination, or when the mind is "at attention". Muscæ are distinctly seen both in sunlight and gas-light when the eyelids are closed and motionless, and their movements are in no way impeded or influenced by those of the lids; they are obviously situated deeper in the eye, and probably, from the rapidity and ease of their gambols, they have a watery medium for *habitus*—that is, the aqueous humour of the anterior and posterior chambers of the eye. It is sheer speculation to speak of their histological nature; but I believe them to originate in minute exudations of lymph or blood, that they elaborate their nutrition by imbibition from their surrounding medium, that their existence is compatible with a life-long retention of the best qualities of sight, and that when their possessor is weary to intolerance, he may hope for a cure in a skilful evacuation of the aqueous humour.—I am, etc.,  
E. HOLLAND, M.D., M.R.C.P., Assistant-Physician to the Hospital for Women.

May 1273.

**SIR.**—Like your correspondent Mr. F. R. Greenwood, I also am a sufferer from the troublesome and annoying affection known as "muscæ volitantes". I first noticed them after a severe attack of enteric fever a few years ago, when at the same time I became slightly myopic. The little transparent beads or opaque spots are constantly dancing in front of the eyes (especially the left eye) during the day, much to my annoyance, though they do not seem to affect the vision much. They can sometimes even be seen with the eyelids shut, and become invisible by gaslight, or in very bright sunlight. I have been told by ophthalmic surgeons that there is no fear of any permanent injury to vision; but I am anxious to get rid of them, if possible, and should be glad of any suggestions for the cure of the affection. I may add, that Mr. Greenwood's explanation of their origin is mentioned by Dr. Mackenzie in the *Edinburgh Medical and Surgical Journal*, No. 164.—I am, yours truly,  
MEDICUS.

## A PLEA FOR OUR HOSPITALS; OR FLOWERS IN THE SICK-ROOM.

**SIR.**—There exists in the minds of many a popular, though ill founded, prejudice against flowers in the sick-room, the idea being that they exhale poisonous odours and are detrimental to health; but this is not the case. Although flowers with a heavy sickly odour should never be admitted into a house at all, those of a brilliant and pleasing colour, either with or without agreeable odour, are much appreciated by the sick. In some of our large and best conducted hospitals, flowers are regularly arranged in the wards. They are sent by railway by some of the country families in the neighbourhood from the conservatories, packed in tin boxes; and we feel quite sure that the liberal donors would be more than repaid if they could witness the joyful and eager looks of the pallid faces clustering around the newly arrived box, and bestowing words and glances of heartfelt admiration upon its treasures as they are one by one drawn forth.

Those who know little or nothing of the daily weary routine of hospital life can scarcely form any idea of the instinctive longing for, and the intense pleasure felt at the sight of, plants or flowers by the sick and their attendants; and it has been found that the patients in the large hospitals of our crowded towns have derived much benefit, both mental and bodily, from the introduction of flowers into the sick-wards; and we feel sure that every medical man of experience will acknowledge that the presence of flowers in the sick-room, especially of a towp patient suffering from chronic disease, is perhaps one of the most valuable adjuncts to his treatment that he can possess. Flowers of a brilliant red colour have exhilarating effect on the mind of the patient, and should always have a preference given to them when there is a choice.—I am, etc.,  
E. M. RAVENHILL, Lady-Superintendent of Nursing.

Stratford-on-Avon, April 1878.

**NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

**DISINFECTION.**

SIR,—In your issue of the 27th instant, you make some observations regarding a so-called new, cheap, and useful disinfectant, said to be the discovery of Dr. Day of Geelong, and I should be glad if you will allow me to remark upon the statements referred to. For many years it has been well known that oil of turpentine and similar substances have the power of absorbing atmospheric oxygen, and that simultaneously an active principle is developed, resembling ozone in certain of its properties. The nature of this active principle was, however, a matter of much dispute among chemists for many years; and I believe it will be granted by those best acquainted with the literature of the subject, that I was the first to prove that this agent was neither ozone nor peroxide of hydrogen (*Journal of the Chemical Society*, June 1874). The substance really produced is an organic peroxide, of the probable formula  $C_{10}H_{14}O_4$ , which by contact with water is gradually resolved into camphoric acid and peroxide of hydrogen (*Journ. Chem. Soc.*, March 1875), thus:  $C_{10}H_{14}O_4 + 2H_2O = H_2O_2 + C_{10}H_{16}O_4$ . Simultaneously with this organic peroxide, other camphoraceous products are formed, and among them a kind of camphor resembling thymol both in its chemical and its antiseptic characters. The study here indicated I pursued for many years, the various new facts which were ascertained being published from time to time (*Chemical News*, Sept. 17th, 1875; Sept. 22nd, 1876; etc.). In the meanwhile, I was aware that Dr. Day had made many simple observations upon a similar subject; that is to say, he had noticed, in an amateur sort of way, what many others had noticed before—viz., that various oils, like turpentine, do absorb oxygen from the atmosphere, and at the same time give rise to an active principle: but the tests employed by Dr. Day were not mathematical in their exactitude, nor did they admit of strictly scientific interpretation. Indeed, the tests used by him do not serve to diagnose ozone from peroxide of hydrogen; and I have already stated that neither one of these substances is produced directly in the atmospheric oxidation of essential oils and other hydrocarbons. It is unnecessary here to refer more particularly to the chemical law by which peroxide of hydrogen is ultimately produced in these processes. Your readers may learn more about this by consulting my various papers previously indicated, and also those in the *Pharmaceutical Journal*, December 2nd, 1876, and the *Journal of the Society of Arts*, February 16th, 1877, and March 8th, 1877.

From a number of considerations affecting the nature of the products formed in the atmospheric oxidation of bodies like turpentine, I was led to believe that the disinfecting and antiseptic properties exhibited by such oils under given conditions resided in these very products, and that initially the original substances have comparatively little value. This conjecture proved to be true, and from the scientific aspect of the question I was led to its commercial pursuit. The solution now well known as "sanitas" is a solution of the products formed in the atmospheric oxidation of turpentine, and other oils resembling it, and, indeed, consists of peroxide of hydrogen (to which the disinfectant characters are in part due) and camphoric acid and other camphoraceous principles (to which the antiseptic characters are due). This solution has many advantages, and among them it may be mentioned that it contains no oil, and is therefore non-inflammable. Now, even on the simplest grounds, there could not be employed on any appreciable scale a disinfectant solution made up of inflammable principles like those forming the basis of the preparation which has called forth these observations. Moreover, it will be at once seen that any disinfectant characters it may possess are due to the generation in its use of those very substances of which "sanitas" exclusively consists. Why, however, a dangerous substance like benzene is used to dilute the turpentine I cannot imagine; the more so because it does not absorb atmospheric oxygen, and does not produce peroxide of hydrogen.

In conclusion, allow me to say that I am surprised Dr. Day should fail to admit the credit of my years of labour in a study which must have given him as much pleasure as it has cost me work and time.—Yours truly,

CHAS. T. KINZETT, F.C.S., Member of the Institute of Scientific Club, April 29th, 1878. Chemistry of Great Britain, etc.

**A FELLOW (Oxford).**—Mr. F. Le Gros Clark, F.R.S., late President of the Royal College of Surgeons of England, will preside at the Fellows' Festival. Mr. Lowne has succeeded Mr. Allingham as honorary secretary, and to whom you should apply for the stewardship.

**CIRCULATORY DISEASES.**

SIR,—Though some practitioners think climate and locality are unimportant in the treatment of certain lesions by rest and diet to induce fibrillation, my own observation convinces me that the breezy higher grounds, of the west—notably north-west Pembrokeshire and south-west Cardiganshire—have a tendency to render the action of the heart far more quiet and regular from day to day and during sleep than any part of the interior of England; and this must have its effect in palliation or cure. There is a cool freshness in the district named in summer, and winter frost is seldom so keen or of such long duration as in England. The prevailing characteristic is mildness and freshness, without the relaxing quality of Devonshire air, and I have often wished some wealthy and benevolent individual would erect a really comfortable sanatorium in the neighbourhood for invalids of the class named, and others similar. I feel sure that many, even incurable cases of cardiac disturbance, would be alleviated, and lives which in the feverish atmosphere of English towns are wellnigh unendurable, might be rendered at least tolerable by a few daily lucid intervals of enjoyment. But of course the building must be made to suit the climate, and have proper aspects in its surroundings to meet the various seasons. One great advantage is, that there is generally very pure water to be had on the site formation, so there need be no trouble with the dyspeptic and irritative complications which the eternal "whitewash" of secondary and tertiary wells induces.—Yours faithfully,

J. C.

**MEMBER.**—It is necessary for our correspondent's son to be registered as a student. The necessary information will be obtained on application to the Registrar of the General Medical Council, 315, Oxford Street, London, W.

**TREATMENT OF TINEA DECALVANS.**

SIR,—Can any of your readers inform me of an efficacious remedy for tinea decalvans? I have found the complaint especially intractable, and shall be glad for more light in the shape of a better remedy. Those tried have been principally parasiticides and stimulants.—I am, etc.,

R. G.

The following communications have been handed to the General Manager:—Mr. A. Graham, Chichester; Mrs. M. Hall, Sheffield; Mr. W. W. Esam, Eastbourne; Mr. T. J. James Brown, Lambister.

**THE M.D. DEGREE.**

SIR,—I have read with some pleasure and interest the letter from M.R.C.P., published in your JOURNAL of last week; his case, I should at once state, is one somewhat similar to my own. I studied at St. Bartholomew's, and after four years of hard work, I came away trebly qualified; but not having the time, and being very anxious to get my living as soon as possible, I was unable to obtain a degree in Medicine. I now find myself much in want of such a degree: a want I did not realise as a student, or think I should when I became a M.R.C.S., etc.

Now, sir, on looking around I do not find the portals of any university open to me (except the Continent) unless I again become a student for a year or two, or wait until I have attained a certain age, or spent a definite number of years in the practice of my profession. In my case, and doubtless it is the case with most medical men, it is simply impossible for me to spend any length of time now at an university; it would be most injurious to my future prospects. I have no desire nor have I such a keen appreciation of Continental degrees (which I believe I am correct in stating are not registrable in England), as to lead me to leave the country where I have studied and practised for years to seek a degree in medicine. I can, I must honestly confess, see no reason why one of the English universities should not grant a degree to men who have obtained certain qualifications, and who have been studying their profession, say, for some ten years. I cannot see it would be in any way derogatory to that University to hold examinations twice a year for such a class of medical men. Give them a searching, long, and, above all, practical examination; demand a reasonable, but not an exorbitant, fee; and those they find well read, quick in diagnosis, and prove themselves good practical men, and well acquainted with their profession, give them, I say, without hesitation, the M.D. degree. The university best suited in England to do this is, I think, the Durham; it has opened its doors to a certain extent, and has shown a willingness and desire to assist qualified men—in the same situation, I take it, as "M.R.C.P." and myself—to obtain the M.D. degree; but I do not think the University has acceded enough. I would most strongly urge it to take the matter again in hand; allow qualified men to present themselves earlier than they do now. I feel quite sure the degree would not lose a particle of its lustre or value, that the number of applicants would be greatly increased, and that an enormous boon would be conferred on aspiring practitioners generally.—I remain, yours faithfully,

MEDICUS.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fifehire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

## AN ADDRESS

ON

## ALCOHOLIC DRINKS: AS DIET, AS MEDICINES, AND AS POISONS.

*The Oration delivered to the Medical Society of London for the Year 1878.*

By ALFRED CARPENTER, M.D., Croydon.

Lecturer on State Medicine at St. Thomas's Hospital.

I HAVE assumed that the establishment of an annual oration is not for the purpose of proclaiming some new discovery, or propounding some new theory, but rather for reviewing the evidence which has been obtained upon some given subject, and which has been, more or less, already submitted to the notice of the assembly to whom the oration is delivered.

From such a standpoint, I propose to deal with "alcoholic drinks". The subject is one of vast importance to the medical world, whether it be considered from a therapeutic or from a sanitary point of view, and on that account no excuse is needed for taking it as the theme of this year's oration.

A review of the effects of alcohol upon a healthy man, as well as of its therapeutic use, may be taken under different aspects, viz., as a diet, or as a medicine, or as a poison. They are intimately associated, and the reasoning which will apply to the consideration under the one head will, more or less, apply to the others.

The use of alcohol as a diet has been strongly condemned, and indeed prohibited, by influential leaders among us. Its usefulness as a medicine has been distinctly challenged, and it has been stigmatised as a poison under all circumstances by some whose professional opinion upon most matters usually commands respect. Others, again, of equal talent and experience, affirm that it is a food of great use, that disease cannot be so successfully treated without it as by its aid; and both sides assert that the chemist and physiologist are able to show us how it acts and how it is removed from the body.

I propose to review some of the evidence which has been produced by these different schools of thought in an unbiased manner, and for this purpose to consider the action of alcohol from a chemical and physical as well as therapeutical standpoint.

I apply the term "alcoholic drinks" to all those liquors in common use as articles of diet in the composition of which alcohol finds a place. The universal employment of this particular class of liquids indicates a natural requirement of some kind. Their use may be condemned as unnecessary, or even hurtful, by sensible men as well as by enthusiasts, just as chimney-pot hats or stays may be condemned; but the condemnation does not prevent their use by the public at large, because the general opinion is that they are necessities; and this opinion is fostered among some of us because it entails no trouble to accept it as true. But that alcoholic drinks are not necessities of life is proved by the fact that millions of people do not use them, and, as far as practical observation goes, those people do not suffer from their non-use. If a number of people be deprived of sugar, of fat, salt, vegetables, or water, the effect is soon manifest; they are necessities of life, and, if they are absent from the diet-table, those omitting to use them as articles of food suffer sooner or later in their health from the exclusion; but those who never touch alcohol in any form never show any distinct signs of evil from its non-use. It is not, therefore, a necessary of life for ordinary people and for common purposes, and if used as an article of diet, it must be considered as a luxury and not as a necessity. It is possible that fluids containing alcohol may be useful in their way, in the same manner as turtle soup and Stilton cheese are useful to those who like them; it will be an advantage to the art and science of medicine if its professors always view them in that light, rather than as things that are absolutely required for the ordinary production of chyle.

Some things which were formerly thought to be luxuries are now considered to be necessities, such as tea and coffee; and it may be argued that alcohol is one of this class; we can do without them, but they are very useful as articles of diet, and, unless it can be shown that they are more injurious than useful, the argument is a good one. I have, therefore, to inquire in what way alcohol may be beneficial when used as a luxury.

I will first dispose of some arguments which are employed both for and against its common use. It is sometimes said that it is an evil thing, which should be put aside altogether; the advice being founded

on the fact that animals will not touch it, and it is said that their example should guide us to reject its use. But, are we prepared to be guided by animals in other matters? They never cook their food or make exchanges among themselves of one kind of food for another, or use artificial coverings. It would be quite as reasonable, on such foundations, to argue against cookery and barter, and to assert that milliners and tailors are unnecessary traders, because animals never cook their food or put on other than their natural coverings. We must look deeper into the case, and get more certain proof against the use of alcohol than this, before we can justly decide that it is hurtful under all circumstances and ought to be dismissed from common use.

The evidence derived from its rejection by animals not helping us, we may look to its effect upon the human economy. There has been a conflict in all ages of the world as to the good or evil effects of wine and strong drink. It has been styled God's gift which cheers the heart of man, as well as the "Devil's draught" which steals away his intellect; but so of sleep, "tired nature's sweet restorer", the author of Proverbs says: "Go to the ant, thou sluggard, consider her ways, and be wise." Sloth is the result of excessive sleep, but we must not banish sleep because "some sleep their fill and take their soft repose". A late writer and noted chemist wrote (in his *Lectures on Food*) that "the universal use of fermented liquors was the indication of their serving a profound physiological purpose and supplying a common want. The fact", he says, "of their use from time immemorial, and that no fluid containing sugar, whether the juice of vegetable matter or the juice of fruit, can be exposed to the air without spontaneous or immediate fermentation, are evidences of useful purpose." This argument is as unsound as that which objects to stimulants because animals do not drink them. We might just as well assume that, as milk cannot be kept exposed to the air without rapidly changing, therefore the changed milk is "evidence of useful purpose", and that articles of diet which, sooner or later, have become tainted, become so that they may "supply some common want".

The first question which we have to solve is, whether any force can be produced out of alcohol, *quid* alcohol, either as animal heat, muscular power, or nervous energy. Is it capable of being at all utilised in the animal economy? Dr. Henry Bennet says (*Nutrition in Health and Disease*, p. 64) that alcohol feeds organic combustion and creates heat, and even Dr. Richardson (*Temperance Lesson Book*, p. 182) says that, "in its first action, it causes the warmth of the body to rise". But there is then a divergence of opinion; on the one hand, eminent men agree with Dr. Bennet, and assert that alcohol is rapidly decomposed and heat disengaged. Dr. Parkes, from his practical observations, was satisfied that it did evolve heat, though it lowered the temperature for a short time after being taken; whilst others equally eminent affirm that there is no utilisation in the ordinary sense, and some say that the whole of the alcohol is passed through the body and is expelled without any of it being changed into force-producing matter. I cannot endorse this opinion, because it is contrary to almost universal therapeutical experience. Every medical man in extensive practice must have seen cases, which now and then have fallen to my lot to witness, in which life has been prolonged for many months without any other nourishment than that which was contained in the spirituous liquors or wines which the patient would alone consume; cases in which it was impossible for life to have been sustained upon the few grains of organic substances which were contained in the colouring matter or extractive of the liquor, or in the sugar which is sometimes given with the stimulant. It has been shown that dilute solutions containing alcohol of about the strength in which it is likely to be found in the body, viz., 1 in 1,000, if passed several times through six inches of a silicated carbon filter, metamorphosed the alcohol into complex products non-volatile at the boiling point of water: the alcohol being changed by this plan of proceeding into glycol, which is considered one of the saccharine group. If this be a possible contingency, it may be transformed into force in the human economy under certain unknown circumstances, and as such it may be useful without danger as a luxury. It may be argued by the austere ascetic that all luxuries are evil, and that they should not be used at all. I need not stay to consider this line of argument. To abolish all luxuries would be to bring enormous misfortunes upon the whole race of mankind, for which there could be no excuse; and I must assume that a luxury which is not immediately injurious may be fairly used by all who can afford it.

It is forcibly argued by some, whose opinion is worthy of deep attention, that alcohol is hurtful under all circumstances. They state that it is immediately injurious to those in health, and that there are other stimulants equally if not more useful, which could be employed in disease. They contend that its ordinary sale should be prohibited on that account, in the same way that arsenic or strychnine is prevented from being a common article of merchandise. Let us now look into

this view of the question, premising again that the individual experiences of those who have been accustomed to the use of stimulants are not in any way to be depended upon for an accurate estimate of their effects, and that their evidence is worthless for scientific purposes.

If alcohol be administered in potent doses to one unaccustomed to its use, there is no doubt of its injurious and even fatal results; but such would also be the effect of the administration of potent doses of phosphorus, sodium, or potassium, and yet they exist as necessary elements in many foods, and are absolutely required to enable the body to be built up properly. Because, therefore, a large dose of alcohol, phosphorus, or calcium is injurious, it does not follow necessarily that a small one is mischievous likewise. Indeed, if lime and common salt are withheld, the constitution is sure to suffer; we have rickets established in the one case, and in the other the body is tormented by parasitic life. We must not assume that, because a large dose is injurious, a small one is so also. Lime and salt are necessities of life, and yet they are injurious in large doses, and it is not an argument against their use in small ones. Alcohol, like lime and salt, may be beneficial if used at the proper time, and it ought not, therefore, to be absolutely prohibited as a common article of commerce unless it can be shown that some injurious sequence is sure to follow sooner or later upon its use in small ones.

We must look a little closer into its action upon animal life before we can solve this point. The first deduction to be made from its continued use is, that the body, after a short interval, becomes very tolerant of its effects, and apparently the more, in moderation, a man takes into his system, the more he can carry without apparent injury. Those accustomed to the daily use of alcohol can take a much larger quantity with impunity than the teetotaler can do. One man may take a bottle of wine and half a pint of brandy every day of his life, whilst another man only takes a bottle on a given day once a week, or three or four glasses of brandy and water on Saturday night. The one may be of the race of "fine old English gentlemen", who never transgresses the rules of propriety, and goes honoured sooner or later, generally sooner, to his grave with blessings on his head; whilst the other becomes a habitual drunkard, a transgressor of the law, and an outcast of society, although he does not consume one-sixth part of the liquor which is taken apparently with impunity by the other. This result shows that conditions vary very much in different constitutions, according to the regularity with which the dose is taken, and alcohol, or some of its constituent elements, collects much more rapidly in some habits of body than in others. It differs within certain limits from most reagents, and helps to protect those using it regularly from its own evil effects. In this it appears to be allied with tobacco, and also with certain miasmatic influences, which require some constitutions to be acclimatised before they can bear that which is manifestly injurious in its first effect, however they may be able to stand against its bad influence after a time.

It is stated by microscopical observers that alcohol acts immediately upon the blood-corpuscles, as well as on the fibrin which is contained in the liquor sanguinis. It is said that one part of alcohol mixed with five hundred of blood interferes with the power of the corpuscles to absorb oxygen; it abstracts water from the blood-discs and makes them adhere together in masses in the blood-vessels; it also causes the plastic or fibrinous part of the blood to coagulate, which then collects in the capillaries, and the current may be thereby stopped.

From frequent observations, I incline to believe that this is true, and that this result explains some of those unfortunate cases which now and then occur to the obstetric practitioner. The free administration of alcoholic stimulants to the weak and debilitated, especially when there has been hæmorrhage or long continued suffering, and perhaps too great dependence on stimulants, has led to the sudden development of embolism. A clot of fibrin has been deposited rapidly in the heart or large blood-vessels, and the patient is dead in a very short time. I have also seen many cases of paralysis and epileptiform convulsion which had been caused by embolism, and which, in my opinion, had been promoted by alcoholic saturation. Such cases have done well, and have ultimately recovered, if alcohol have been superseded; but, if it have been persevered in, in most instances which I recollect, there was a continuation of the disease. An excessive quantity of alcohol does impede the purification of the blood, and the elimination of carbonic acid, by obstructing endosmose and exosmose in the lung-capillaries; the purple tint which pervades the skin of the regular toper is sufficient proof that this is true. Observation shows that the exhalation of carbonic acid is decreased in quantity after the imbibition of alcohol.

Whilst these are undisputed facts as regards large doses of alcohol, it has not been shown that a similar result follows from the smaller quantities which are found in the weaker drinks, such as natural wines and weak beers.

Alcohol is not cumulative under ordinary circumstances, or the man who takes his bottle of wine daily would suffer more and sooner than he who only takes a bottle one day in the week; but it is cumulative under some conditions at present unknown, and in which it is probable that the ordinary elimination or oxidation is interfered with, so that the toper, who could formerly take his bottle with ease, gets quite drunk by taking three glasses of his favourite liquor. One very eloquent writer, and former orator to this Society, says that "we may trust a great deal to instinct, and that tastes are, generally speaking, expressions of the wants of the system". I consider this a most dangerous argument to use; for no man taking stimulants can be himself aware of all the harm that they may be doing to his constitution, or know the time when they may become cumulative. All those who indulge in any kind of vicious practices would be glad to be able to rest upon such a dictum, and to affirm, and excuse themselves by affirming, that their vicious tastes "were but the expression of the wants of the system".

It appears to be supported by a sufficient weight of evidence that, when once the system has been exposed to the full influence of alcohol in such a way that a portion of the blood has been so acted upon that its discs have become corrugated and some of the fibrin coagulated by its action, a cumulative effect may begin, and with that cumulative effect there will be developed a taste for more which prevents the instinctive desires of the individual from being any guide as to the real wants of the system so long as any altered material exists in the blood. The lightest kind of wines generally contain ten per cent. of alcohol, so that they must be diluted with five times their amount of water to reduce them to a harmless condition. The reduction is seldom effected in this country, although the general consumption at the dinner-table of saline waters, which has lately come into fashion, is tending greatly in the direction indicated. Porter, stout, and ales all contain at least double the amount of alcohol beyond that which would make them safe for absorption at all times, unless freely mixed with other things. To take them, therefore, on an empty stomach tends more rapidly to bring about the point of saturation than when food is taken with the drink.

Alcohol transudes most rapidly through membrane, the rapidity of transudation varying very much according to the stage of dilution, and in its transudation it acts upon the membrane. It is quickly conveyed to all parts of the body, and we have no means of judging where it is likely to manifest its first effects, neither have we any means of knowing when the limit is reached beyond which it will not be safe to allow blood-disturbance to proceed. The alteration of shape of a few blood-corpuscles, the interference with their diffusive power, the interference with the transudation power of membrane, or the coagulation of a few grains of fibrin, are of comparatively little consequence, especially if the place be one of secondary importance; but when the number of altered corpuscles passes beyond a certain percentage of the whole volume of blood, evil must result. This percentage is much more rapidly reached in some habits of body than in others; it will depend very much upon the power of those organs to do their duty whose function it is to remove the altered fibrin and imperfect oxygen-carriers from the circuit. If they be defective, deterioration will be much more rapid. Thus, of two men, each taking the same quantity of liquor in the course of a month, one taking it only with food and the other on an empty stomach, the latter becomes rapidly saturated, the former escapes without serious damage.

If coagulated fibrin be not removed as soon as coagulation takes place, if it gravitate to some one organ and impede circulation there, we have the commencement of those organic changes which are constantly found in the bodies of the intemperate classes, by means of which their habits are unerringly revealed to the pathologist. The fibrin may be removed at first without setting up mischief; but the altered blood-corpuscles and interference with physical power of membrane increase the evils which arise from want of oxidising power, and fatty degeneration sooner or later follows.

Here is the great difficulty which meets the view of all those who have considered the action of alcohol in an unbiased manner, and which has led so many among us to become total abstainers. They refuse to take alcohol as a luxury. The evil is so great and the resulting good so small, that they prefer to do without the good and so avoid the evil; and, as society is at present constituted, they are probably right. Still, the lighter wines, if entirely unfortified, and the weaker beers may be taken with impunity; they may even assist digestion, and be of advantage with or immediately after food. If taken with other food, when great exertions are being made, and when there is a call upon the stomach for fuel to supply waste of tissues, there is sufficient evidence to show that they enable the machine to obey that call with better effect than would be the case if stimulants were altogether withheld; but, if the effort be continued from day to day beyond the ordinary capacity of the machine, and that effort be sustained by more fuel

in the shape of stimulant, the human machine, like all others, must wear out sooner than it would otherwise do.

Whenever, therefore, the consumption of alcoholic drinks exceeds the quantity which gives rise to the probability that more than one part of alcohol to five hundred of water may exist in any part of the circulation, harm, in some form or other, must result. That harm need not necessarily be permanent, and its cause may be removed altogether from the system, or it may be partially removed, a particle of matter being left *in situ*, which acts as a foreign body when alcohol is again taken, aggregating to itself fresh coagulated matter or freshly agglutinated corpuscles, by which the symptoms of alcoholic excess are rapidly induced when those particles are situated in any of the primary nerve-centres.

We may fairly assume that there are occasions in which stimulants may be useful and even necessary; but as habitual drinks they must be hurtful, unless more diluted than we are accustomed to take them, and it appears to be our duty as medical advisers to forcibly state this fact to those consulting us, and to advise their non use in daily life.

Having come to this conclusion as regards their use as common articles of food, we may now inquire when they are likely to be beneficial as medicines. To enable us to answer this question satisfactorily, we must study their effects a little more closely than we have yet done.

A stimulant in moderate doses promotes the secretion of gastric juice; it brings a flush of blood to the capillaries which surround the gastric follicles, producing congestion immediately. This is relieved by a free flow of gastric fluid, and the rapidity of digestion is promoted. But the action is followed by a reaction, and the next day there is a deficiency of gastric juice, and, as a consequence, a want of appetite. The deficiency may be remedied by another dose of the irritant. The dyspeptic symptoms are relieved for the time being by a "pick-me-up", and so each daily exhibition leads to increased dyspeptic disturbance, until the follicles are so altered that the whip no longer acts, and the general health fails. If an excess of stimulant be taken at any one time, it acts immediately on the pepsin in the gastric juice, as well as the lining membrane on the vessels, and destroys the power of digesting and rearranging the materials which are contained in the food.

The rapidity of the current of blood being delayed in the capillaries of the stomach, their tension is interfered with, they dilate, and a larger quantity of blood is present than is right; as a sequence, local warmth is promoted, and, in vulgar parlance, "coppers are hot". But it has been fully proved by accurate observers, that the quantity of heat in the body is not materially added to by alcohol, but that, on the contrary, there is a reduction from the general amount in consequence of the loss which arises from increased radiation from the surface of the body. The temperature of the "dead drunk" man is lower than that which usually marks the natural heat of the body. This rule does not obtain at all times, as there are exceptional conditions which occasionally modify it. A dead drunk man often has some disease going on in his body which raises the temperature to above 98.5 deg.; but if there be no active disease, and if the temperature of the body of an insensible person be found below the natural standard without any evidence of collapse from any other cause, it may be safely assumed that he is drunk rather than that he is suffering from active cerebral lesion.

The picture which I have drawn of the gastric vessels may be found in any other organ of the body. There is dilatation with reduced power of contraction. This vaso-motor paralysis, so to speak, is more continuous as well as more complete in some organs than in others, and some forms of alcoholic drinks produce it much more certainly than others. This is the case if the alcohol be impregnated with some of its allies, especially amylic alcohol and fusel-oil; these latter are always more or less present in potato spirit, with which wines are commonly fortified. The influence of these alcohols is very decided upon the nervous centres; they immediately produce some of those exaggerated forms of drunkenness in which violent excitement and maniacal delirium are manifest. They make the fluid pleasanter to the taste; and some of their forms are frequently added for the purpose of producing a so-called "bouquet". Their effects are far more serious and immediate than those which follow from the simple use of ethylic alcohol. Time fails me to do more than simply allude to this important point. It may be that some conditions of the body, which arise from a continuous soakage with alcohol, may enable it to change ethylic alcohol into some of the heavier forms: fusel-oil may be manufactured, so to speak, in the human economy itself. The odour of the breath of a dead drunk man is often more than the odour of alcohol; but upon this point chemists have not yet afforded any safe information.

It is uncertain whether the congestion arises from an immediate action upon the tissue of the capillary, or whether the first effect of the alcohol may not be on the nerve, or whether an effect upon the nerve-

centre may not also accrue, as well as a local effect be produced before vaso-motor paralysis can arise. It may, like the blush of shame or the pallor of fear, arise from direct nerve influence, or it is possible that the blood, altered by the alcohol, may be unable to affect the nerve-centre so as to exert its controlling influence upon the particular set of capillaries more immediately concerned, or it may act in different ways according as the membrane is or is not altered by the alcohol. Be it as it may in its first origin, the effect is to interfere with the proper renovation and nutrition of the part and to commence a disease of the particular organ affected. Dyspepsia is the first outcome of the use of stimulants, and as a sequence to a common result, viz., inflammation of Glisson's capsule, we may have so-called cirrhosis or fatty degeneration of the liver, and similar changes may take place in the kidney; the heart and large blood-vessels suffer directly or indirectly; the muscles may be destroyed, or the nerve-tissue of the brain or spinal cord may be the parts which show the effect of the reagent first.

There is another class of disease not always so clearly identified with the administration of alcohol. I seldom meet with acute neuralgia in the total abstainer, whilst hysteria is in a great measure absent in those families whose ancestors have been perfectly temperate people. I have traced back several cases of strongly marked hysteria, and in all I have found a certain dependence upon alcohol, not only in the patient, but also in the patient's immediate ancestors. I have met with numerous cases of acute neuralgia in highly sensitive females; it is generally styled agony in those who are hysterically inclined; some declare that it is only relieved by alcohol, or chloral-hydrate, or some other narcotic. The medicine allays the pain if given in sufficient doses; but, as the effect of the dose goes off, the disease returns with still greater intensity until, at length, the stomach rejects the remedy, or some other circumstance comes into play which causes it to be laid aside. The pain has then to be borne with for a time, but after two or three days of comparative abstinence, the pain subsides and the patient is in comfort. There is then, from some accidental cause, a transient return of pain; the stimulant or the narcotic is again resorted to; it relieves for a short time, but that relief is purchased by a return of acute pain; there is soon afterwards another paroxysm, and the whole course is gone over again.

A close attention to numerous cases of this kind, both in high life and low life, has satisfied me that, so long as the alcohol is given sufficiently in excess to induce moderate vaso-motor paralysis, there is relief from the pain; but, as soon as that influence lessens, there is an aggregation of altered fibrin, microscopic in quantity, either in the capillaries which supply the sentient nerves or in the nerve-cell itself, which sets up an irritation, which is felt at the periphery of that particular nerve, and neuralgia results as a sequence of that irritation.

Many kinds of so-called rheumatism have a similar origin. The imbibed alcohol affects different parts of the cerebro-spinal nervous system, according as the result attaches itself, as altered matter to one or other class of nerve-cell, and neuralgia, or rheumatism, or rheumatic gout, as they are often called, or even gout itself, is the outcome of the action.

The cases of neuralgic disease, to which I more especially refer, occur in highly hysterical constitutions, and are not generally accompanied by any cutaneous capillary congestion, except when neuralgic pain is absent. There is sometimes great mental power in this class of cases, a brilliant intellect or great genius, which only shows itself when the cerebral capillaries are congested and the cutaneous system gorged with blood. These cases generally go from bad to worse, and end in suicide, or as general paralysis or dementia. The tissue of the brain and spinal cord being subject to changes which correspond, in a great measure, with those diseases of liver and kidney which are induced by alcohol, a low form of inflammation is set up first, and after that atrophy from impaired nutrition or fatty degeneration, ending in so-called white softening.

There is also a class of cases, not so generally attributed to alcohol as a cause, which I believe to have their origin in its habitual use, which are due to spinal irritation, and are sometimes called spinal neuralgia.

If time would allow, I could detail to the Society numerous cases in which so-called rheumatic pains have continued month after month and year after year, apparently relieved for a time by the use of stimulants; but the use being always followed a day or two afterwards by renewed pain and general distress, and yet the amount of stimulant taken has been in no way excessive. In such cases, I have omitted the use of stimulants altogether, and, after a few weeks of further suffering, the pains have subsided and there has been a fair recovery. Once or twice, I have suspected locomotor ataxy, which developed when the patient has persisted in the use of stimulants, but it has not done so when they have been given up. Such cases are generally associated with a lithic acid diathesis. However much we may try to cure them, we cannot succeed effectually unless we enforce total abstinence, even putting aside

pharmaceutical tinctures. The plan is often given up by the patient too soon; he finds that the pains are at first even more severe; he becomes disappointed and low spirited; then some acquaintance advises him that abstinence is doing him harm. He takes stimulant unknown to his doctor, he feels renovated by it, his pains are eased, and he falls back into his old habits before there is time to effect the removal from his body of the remains of former doses of his favourite drink. He is then quite convinced that the treatment is wrong, and he will not continue it, whilst, if he had persevered a few days or weeks longer, he would have found relief and been on the high road to obtain a perfect cure.

These cases are allied to those of the habitual drunkards and so-called dipsomaniacs, who are persons who have produced so much mischief in their nerve-centre that they are unable to take even a moderate amount of stimulant without a catarrhal state of the stomach supervening, which at once gives rise to an irresistible drink-craving from which they have no escape if they can obtain alcohol. In such cases, there is always an altered state of blood-vessel, or some interference with the nutrition of the cerebral organs, such as a varicose condition of the arterioles or small veins in the nerve-structure, the result of alcoholic excess, which is at once renewed by each application to the wine or spirit bottle. There may be in such cases a cirrhotic condition of some of the glands, or else a fatty degeneration which is incompatible with healthy vigour. These conditions may be removed in their early stages, as well as all other morbid results which are not self-productive, if proper measures are taken to promote their removal. The first and most important step is the immediate and total abstinence from all kinds of alcoholic drink.

The principle upon which we propose to cure the habitual drunkard is to restrain him from the use of his liquor, so that he may entirely recover his health and his power of self-control. There are several stages in this process. First, his digestive power has to be restored: a very difficult and a very slow process. Then the deposits which have already taken place in his glandular system, his blood-vessels and nervous centres, have to be removed, and altered membrane has to be restored. Simple food with healthy habits of body reduce the alcoholic saturation to a minimum, and enable the patient to get healthy digestive power.

The dyspeptic state must be cured before the alterations in glandular organs can be removed; they must do their duty properly before the nerve-tissue can be renovated; and, until the whole are restored, any return to alcoholic diet is followed by relapse. It is only by long continued self-denial that cure can be effected. That I have not overdrawn the picture as to the condition of the nervous system and the seat of disease in such cases, is shown very fully by Dr. Magnan in his work on *Alcoholism*, which has been translated by Dr. Greenfield. It abounds with instances which prove most clearly that the immediate action of alcohol is to dilate the capillaries of the nerve-centres, increasing them to three or four times their ordinary dimensions, and thus paving the way for that atrophic degeneration which is frequently associated with other changes in advanced states of alcoholism. The cases detailed by Dr. Magnan are very instructive; and, if taken in conjunction with others, in which, with similar symptoms, the microscope reveals changes which were formerly unsuspected, we cannot doubt at all as to cause and effect.

The hallucinations and delusions which accompany excess of alcohol even in young beginners are associated with capillary dilatation; and, as a sequence, there is a pressure on nerve-substance which cannot be repeatedly renewed without the risk of subsequent atrophy or degeneration of one part or another of the tissue immediately affected.

Is it to be wondered at that cure in such cases is only to be obtained by long continued treatment? Is it a fair objection to take to long continued treatment, that relapses are common? Can relapse be considered a reason for not attempting cure; and is it to be endured that, with a knowledge of the capability of cure, we should not have power given to us to attempt it, because the disease is said to be the result of a vicious habit?

An opinion was expressed to the Lords' Committee on Intemperance that dipsomania is a kind of epilepsy, and that its attacks correspond with the latter disease. I cannot think that there is any foundation for this idea, any more than that attacks of asthma or any other recurring disease may be epileptic. That dipsomaniacs often become epileptic is undoubtedly true; but many forms of disease tend to set up epileptiform attacks before a fatal termination arises. Epilepsy will arise in any kind of constitution; but drink-craving will only be induced in those who court its advent by taking excess of alcohol.

Another eminent physician, who agreed in the main with Dr. Brunton, expressed an opinion that habitual drunkenness may be cured

by punishment; and that, if its victims were brought under the influence of good education, and some reasonable punishment inflicted, they might be trained to good habits. I do not think so, unless alcohol is rigorously withheld. Some of the worst cases of dipsomania that I have met with have occurred in highly educated individuals; and it is found, by overwhelming experience in the magistrates' court, that punishment has no deterring effect in preventing drunkenness in those who have been two or three times convicted, and who have lost their self-respect and power of self-control. The inconsistency of such an argument is seen at once; for such cases may be epileptic, and yet they are to be dealt with as criminals and punished accordingly.

It is true that, if the alcohol be withheld, the so-called "epileptoid attack" will not come on; for, like the so-called "sunstroke", it is in a great measure caused by the imbibition of drink; but it is not consistent with our ideas of justice to punish a man because he has had either of the conditions mentioned, which are undoubtedly diseases. The frequency with which the plea of sunstroke is urged as a reason for mitigation of punishment by the drunkard in the dock of a police-court is not a little remarkable; and, although I have never myself allowed that plea to be used in arrest of punishment in those cases in which the free will of the individual was manifest beforehand, yet it did sometimes avail when the individual was not a free agent. The plea set up has satisfied me that there is an intimate connection between the embolism which causes the so-called sunstroke and the alcoholic soaking in which the victims indulged. Like to outbursts of passion and to other vicious practices, there is an inability to exercise free will at first; but

"Facilis descensus Averno,  
Sed revocare gradum, superasque evadere ad auras,  
Hoc opus, hic labor est."

The work and labour required to return to the right path are greater than most men, unaided by restraint, are able to use. The battery of nerve-force, in which free will and the higher orders of mental powers are produced, is damaged by the reagent, and is unable to set up those actions which are required for the production of self-control and self-respect. Thus that which was a vice in its early stages becomes a disease later on in life.

The man who refuses to exercise his own self-control when he has the power, after a time becomes a nuisance and a scandal to society at large. He is slowly committing suicide, and is ruining the happiness, and probably the worldly prosperity, of his immediate relations. He ought to be deprived of his liberty to do wrong to himself and others, until such time as his tissues are restored to that state in which his power of self-control may be regained.

So far, the effect of alcoholic drinks seems to be for evil and not for good; and some persons ask very pertinently why they should be retained at all in the *Pharmacopœia* as therapeutic agents, when other stimulants might be used with as much advantage in those cases in which they appear to be required. But so powerful a means to evil, like every similar thing, may be used beneficially, if used aright. There are conditions of the body in which it performs a duty more satisfactorily than any other stimulant. It seems to preserve the body from decay, performing a vicarious duty, being sacrificed itself, and so saving the patient's life. It interferes with the normal changes which are required for the continuance of health, and retains the products of tissue-change in the blood; but in certain forms of disease, when the blood is rendered impure by the retention of those matters which should be excreted, if the retention have not been caused by alcohol, and great heat be developed in consequence of the combustion or oxidation of such matters, alcohol seems to take the place of those of the tissues which are oxidising; it lessens temperature and saves the fabric from death. This effect is seen most frequently in some zymotic form of disease; there is a great tendency to sloughs and bed-sores, which tendency is materially diminished in those who have had alcohol administered, as compared with those who have not.

The therapeutic effects of alcohol, when exhibited in certain typical forms of fever, are most marked. The cases which require it are those in which there are a dry tongue and skin, no sickness, and no indication of cerebro-spinal lesion. If there be any indication of the latter with a moist tongue, stimulants universally do more harm than good, because the tendency is then to increase the congestion upon which the lesion depends. When a case is benefited by alcohol, there are soon produced a lessened temperature, a slower pulse, a moister tongue, and a quieter condition of system generally.

In these cases, the effect of alcohol has to be most carefully watched, and the moment there is evidence of cerebro-spinal lesion or of alcoholic excess, its use must be discontinued. I have seen patients in serious danger, which has been brought about by the wine and spirits

which have been too freely exhibited, rather than by the disease itself. There is something so utterly repugnant to all moral feeling for a medical prescription to be the instrument by means of which a man is sent *drunk* out of the world, that I need hardly insist in this assembly upon the necessity of watching for the probability of such a result. But, in those cases in which the remedy is beneficial, it may sometimes be freely pushed in a marvellous manner with most excellent results.

The cases in which the temporary administration of alcohol may be useful are those in whom the surface of the body has been chilled, and in whom the powers of life are weakened in such a manner that the heart is unable to do its work of propelling the blood to the capillaries with its usual ease. The action of alcohol in these cases acts something like taking off the pendulum of a clock; the spring is able to work so much faster, and to get over an extra amount of beats in the same space of time. Internal congestion, irregular circulation, so to speak, fulness in one place, with unfilled cutaneous capillaries, are cases in which alcohol may be exhibited with immediate advantage. The tension of the capillaries being overcome, there is a diminution of the impediment to the flow of blood, and, as a sequence, a possible diminution of the internal congestion. So, if the action of the heart itself be too weak to overcome the tension of vessels, we may induce a kind of vaso-motor paralysis to enable it to do its work more easily for the time being, and get over a passing difficulty in that way. How far it is prudent to push this vaso-motor paralysis for any length of time is another matter, as a continuance of it must lead to the first stages of tissue-change, which then becomes itself of primary importance.

There is a class of persons to whom alcohol may be useful even in comparative health. When the powers of life begin to decay, when the force of the heart is not enough to transmit the blood to the extremities of the body, and the aged person feels the influence of cold, the blood scarcely passes through the unfilled cutaneous capillaries; by dilating them and diminishing their tension the heart is relieved and the functions of the skin and other organs are more efficiently performed. A moderate dose of alcohol taken with food is always beneficial to an old person under such circumstances, and I cannot see any reason why it should not be administered. Again, there are conditions sometimes present in youth in which alcoholic drinks also are useful; no other kind of stimulant acts so equally and so satisfactorily; there are a few cases—and a very few only—in which they may be administered in middle-age; taken as a whole, a weak heart with unfilled cutaneous capillaries will be always found in those cases in which it is likely to be beneficial. The stethoscope most clearly reveals them, the impulse of the heart and the general rhythm of the pulse not at all corresponding.

So long as alcohol is taken only in such quantities that it becomes utilised at once in the equalisation of animal heat, no harm can result, but if there be more than sufficient to do this, and its specific action be produced on the blood itself, mischief sooner or later results. In this it differs from fat, with which it seems to be allied as a diet, which, if not used up, may be stored in its proper place out of the way, but the changed matter which arises from an excess of alcohol is always stored in the tissue of an organ. Thus its effects may find a home in the capillaries themselves, interfering with their elasticity, or it may be laid down in muscular tissue, and there is then a decrease of power and so-called rheumatic pains are produced. If nerve-tissue be the seat, there is interference with the power of thought, with volition, self-control, and other mental actions, the effect of which is to render the patient a weak-minded and unstable character. In a state of health, it does not prevent the waste of tissue, whilst it does prevent the discharge of effete products. There is a decrease of the formation of carbonic acid, and in this is probably found the reason why there is a decrease of temperature. It stands in the way of more beneficial actions unless it be at once used up. If there be no muscular exercise going on, or no extra mental labour called for, and no action at all required except that which keeps up temperature to a normal standard, it is hurtful; work which is kept going by continual doses of alcohol always ends in a break-down. If it be taken for the purpose of increasing muscular exertion, ultimately there is great loss of muscular power, as athletes well know. If mental exertions be kept going by alcohol, there is mental break-down, as the lunatic asylums testify; whilst it is quite impossible for organic life to be performed in a healthy manner if alcohol be habitually used to promote digestion. The evidence which was afforded by the Abyssinian and Ashantee campaigns and the Arctic expedition help to prove this, whilst the unanimous opinion of those who are competent to judge informs us that, in the Russo-Turkish war, the temperance of the Turkish soldiers enabled them to bear injuries with impunity, whilst similar injuries easily caused the Russians to succumb.

It has been argued by some experts that it is unwise to leave off

alcoholic drinks at once; that it is better to do it by degrees. I never could see any reason for this. The experience of all gaol surgeons is in accord with my idea, that no evil, but real good, results from immediate and total abstinence. I am satisfied that when mischief is arising from its use, it is best to immediately desist from it. If mischief then result, it is because it had already commenced, and not from the abstinence; although when a man has been accustomed to his daily dose of alcohol for a long series of years, and his constitution has become acclimatised without evidence of tissue-change, he should not abandon its use. I could not advise an old man to give it up; such a change would certainly do harm, not good.

I cannot leave the subject of nerve-disturbances produced by alcohol, without referring to the connection which exists between intemperance and crime and lunacy. Statistics are not to be depended upon, because they are not drawn up with scientific accuracy, neither are they usually based upon similars. Yet there are some facts which are something more than coincidences. There is an undoubted increase in the consumption of alcohol per head of the population. The report of the Select Committee of the House of Lords on Intemperance tells us that the consumption per head in the United Kingdom of the following articles in 1876, as compared with 1861, had increased.

	1861.	1876.
British spirits .. ..	0.68 gals.	0.91 gals.
Foreign spirits .. ..	0.13 "	0.35 "
Wine .. ..	0.37 "	0.57 "
Malt .. ..	1.61 bus.	2.02 bus.

The increase year by year was progressive.

The same progressive increase was observed with regard to crime.

	1861.	1876.
Committeals for drunkenness .. ..	83,196	203,935
Committeals for assaults .. ..	85,443	122,913

There is also a rise in the number of lunatics which the increase of population does not account for. In 1861, there were 39,645 under the supervision of the Lunacy Commissioners; whilst in 1875 they had increased to 63,793; and out of thirty-nine medical attendants of lunatic asylums who were consulted by Canon Ellison, thirty-two replied that, in their opinion, there was a distinct connection between an increase of drinking and lunacy as either cause or effect.

The Chief Inspector of the Metropolitan Police shows us that 251,125 persons were charged at the various police-courts in the Metropolis with drunkenness in the ten years ending 1876. That more than a quarter of a million of persons had within ten years recklessly thrown away their liberty of action in the eyes of the public, by rendering themselves slaves to a vicious habit, is a fact which must make men thoughtful as to the future of our people.

The poisonous nature of alcohol in large and continuous doses has never been doubted, and no one can study its effects on the death-roll of this country, or read Dr. Magnan's work on Alcoholism, without being thoroughly satisfied on that point. Dr. William Farr, in his supplement to the thirty-fifth annual report to the Registrar-General, tells us that those who supply the community with drinks, food, and entertainment in inns and beerhouses are shown to suffer more from fatal disease than any known class. He says also that the majority of the publicans and the greater part of the wine merchants are comparatively temperate; yet, as the mortality of the whole trade is high, the mortality of the intemperate among them must be excessive. In the same report, the deaths amongst those engaged in the sale of stimulants is returned at 2,538 out of 74,367 persons so occupied, which gives a death-rate of 30.4, whilst 1,988 blacksmiths are registered out of a gross total of 108,939, a death-rate of only 18.2 per 1,000; that of men in all industrial occupations was 19.9. The report tells us not only that the poisonous effect is undoubted, but that the effect is progressing in an increasing ratio. Thus we find that in the year 1857, 323 deaths were reported in which the verdict of a coroner's jury was death through excessive drinking; in 1875, the number had increased to 516. It also tells us that, whilst in 1857 294 deaths were directly attributed to intemperance, 569 were so registered in 1875. The deaths from delirium tremens also reached the number of 485. Thus in one year, 1875, we actually have 1,566 deaths, in England alone, directly caused by alcoholic poisoning—not one-hundredth part of those which are hastened by alcohol. But supposing 1,566 deaths had occurred from hydrophobia or serpent bites, or had happened to passengers on the railways in the kingdom, commissions and edicts and proclamations from Privy Council would have been issued, and Acts of Parliament would have been rapidly passed to provide against the continuance of this wholesale slaughter. Not so, however, with the poison of alcohol; it works its way, in a great measure unheeded by the Legislature, except so far as it is made to be a means for increasing revenue by increasing the sale of the poison itself.

I have endeavoured to prove the truth of the proposition by statistical data obtained from the Registrar-General's publications, attested by the returns of the Census Commissioners; but, unfortunately, they do not refer to the same districts and are not based upon exactly the same foundations, so that the data do not correspond. There are, however, some striking points made out. Thus, taking the "England Tables" the mortality in the year 1871 among ministers of religion was 666; of these, 464 lived to be over forty-five years of age, or 69 per cent. Taking the number of deaths among gardeners—men much exposed to vicissitudes of climate—1,949 died; and of these, 1,335, or 68.2 per cent., lived more than forty-five years. Then, passing to the other end of the death-roll, I find, out of 725 brewers who died in the same year, 294, or 41 per cent., only reached the age of forty-five; and of 2,728 publicans and eating-house keepers who died, 49 per cent., or 1,330, were over forty-five. These facts show that the occupations which bring men into contact with the sale of alcoholic drinks materially shorten their lives.

When we come to deal with the character of disease which causes death, statistics do not help us. I have waded through an immense mass of figures without satisfactory result; for upon this point statistics prove nothing. A reference to the physiological effect of alcohol will easily explain why this is so. I have shown that its effects may fall upon any one of the excretory organs or upon any part of the nervous system. It follows that a very large number of persons may die from disease induced by a too frequent application to alcoholic drinks without the remotest suspicions in the minds of themselves or their friends that such is the case. Disease of brain, heart, lungs, kidneys, stomach, indeed of every organ of the body, may have its first origin in alcoholic excess, although the person so affected may be a temperate man and have never been drunk in his life. I have, therefore, been reluctantly compelled to put statistics aside. I have also looked carefully into the reports of the National Temperance Hospital, and have compared it with reports of similar institutions in which stimulants are freely used; but as the results, as based upon the reports, are fairly open to objection, I do not use them here. The difficulty of obtaining the life-history of a given case renders all hospital returns unsafe and unsatisfactory as bases upon which to found a basis for the treatment of disease. That temperance does promote length of life is a truism which even the intemperate are ready to grant, although we have not much statistical proof of its soundness. I may, however, support my statement by a return which has been kindly given me by a director of the Temperance Provident Life Office; being a statement of mortality from 1866 to 1877. The insured lives are divided into two sections: teetotal and general. The temperance section gives, as the result of twelve years' working, 1,619 claims expected, the actual number being 1,156; whilst in the general section, 2,846 claims were expected, 2,807 were made. The claims in the temperance section were 28.5 below the expectation, whilst in the general section they were 1.4 per cent. below only. This return is a clear proof of the commercial value of abstinence.

In concluding my subject, I have only to remark that alcohol in any of its forms may be a good medicine, but is a bad diet, and that its action as a poison is visible among all ranks of society. It is our duty as medical men to advise our patients accordingly.

**WORCESTER.**—The estimated population in 1877 was 34,626; the deaths 865; and the death-rate consequently 24.95 per 1,000, and the zymotic death-rate 4.2, which is much in excess of the average, in consequence of the great mortality from measles, scarlatina, and diphtheria. Dr. Strange states that he has inspected the whole of the district during the year, and especially the poorer houses; and finds a great improvement in their sanitary condition as compared with former years, as roofs have been made watertight, yards better paved and drained, and the interior of the houses is more cleanly. Articles of food were analysed, and found to be fairly good; the mortuary is finished; and the removal of nuisances has been fairly carried out.

**CREWE.**—Dr. Lord reports that a special inquiry was made during the year as to the sanitary condition of the workshops, lodging-houses, bakehouses, slaughter-houses, piggeries, etc.; and fifty-six notices to abate nuisances on these premises were consequently served. The water-supply is good, most of the sewers ventilated, and the streets kept clean; but he says that the ashpits are a great nuisance. The birth-rate was 37.5 and the death-rate only 14.1 per 1,000 living, against 15 in 1876. Dr. Lord, however, is not satisfied, as there were nearly 50 per cent. of deaths under five years of age. The chief mortality from zymotic diseases was caused by scarlet fever, and the next by typhoid, viz., eleven; but no special cause is given for these deaths.

## CLINICAL LECTURE ON AMPUTATION AT THE HIP-JOINT:

CASE ILLUSTRATING A NEW METHOD OF COMPRESSING  
THE COMMON ILIAC ARTERY.

By RICHARD DAVY, M.B., F.R.C.S.,  
Surgeon to the Westminster Hospital.

GENTLEMEN,—I shall endeavour to-day to engage your attention on the gravest amputation in surgery, viz., that at a hip-joint. For the practical elucidation of this lecture, I will read the notes of the boy's case who is now in this theatre; next I will describe in detail the method of operating; and will lastly carry out the whole procedure on the dead body.

C. C., aged 9, school-boy, was admitted into Mark Ward on July 10th, 1876, suffering from morbus coxae (femoral and acetabular) on the right side. In 1874, he had two severe falls, one especially from a cliff near Varmouth; pain in the right hip and lameness set in at once. Some months afterwards, swelling and puffiness were noticed over the right hip; the abscess, however, did not open over the articulation, but burrowed along the adductor group of muscles; and, in June 1875, a sinus formed at the junction of the middle and lower third of the thigh. Suppuration was watery and profuse; the limb became everted and drawn up towards the abdomen. He was admitted because alarm had arisen from his emaciation. From July 1876 until January 1877, he was kept in the recumbent posture; had a most generous diet and quinine; rest to the joint was maintained; and at times he was slung in the open air in a hammock. The boy was so surely losing ground that, on consultation, it was agreed to remove the right thigh at the hip-joint.

*Method of Operating.*—In all severe amputations, one of the first considerations of the surgeon is to anticipate shock and to prevent the loss of blood. I am inclined to permit any patient to have a glass of wine or brandy and water about one hour before the operation; the result partakes more of a sedative than stimulating character; apprehension is lessened; cardiac tone is gained; fitness for the ordeal is exhibited. The American surgeons, with their characteristic ingenuity, devised pressure on the abdominal aorta for hæmostatic ends during amputations high up towards the pelvis. Lister arranged a horse-shoe clamp and screw-pad for compressing the aorta above the umbilicus. I saw this mechanism (1860) used in Symes's brilliant operation on gluteal aneurism at the Royal Infirmary, Edinburgh; but in 1874, during the delivery of the Surgical Lectures at the College of Surgeons in London by Professor Holmes, I drew the lecturer's attention to the possibility of controlling the aorta, common iliacs, and internal iliacs by pressure through the rectal wall, and wrote the following note to the BRITISH MEDICAL JOURNAL.

"June 20th, 1874.—*Compression of the Internal Iliac Artery.*—Sir, —Mr. Holmes, in his lecture on Gluteal Aneurism at the Royal College of Surgeons, June 8th, mentioned the late Mr. Symes's case, treated by boldly laying open the sac, and restraining the hæmorrhage by Lister's aortic clamp. It may be well to draw surgical attention to the fact that the internal iliac artery may be effectually compressed for a time by pressure through the rectum on the true pelvic wall; a less serious procedure than compression of the aorta through the abdominal wall.—I am, etc.,  
RICHARD DAVY."

On January 16th, 1877, this case presented a fair opportunity for testing the suggestion. The right leg and thigh were emptied partially of blood by Esmarch's bandage. Chloroform was administered, and about one fluid ounce of sweet oil was sent up his empty rectum. A straight lever of wood (run smooth and round out of a lathe) was introduced *per rectum*; the small end was applied over the right common iliac artery between the lumbar bodies and psoas magnus muscle; the projecting part of the lever ran nearly parallel to the left thigh.

My colleague Mr. Thomas Bond readily compressed the common iliac artery by elevating the projecting arm of the lever, the perineal tissues acting as a fulcrum. Accordingly, as Mr. Bond elevated or depressed the lever, so did the right femoral artery cease or continue to pulsate. The left femoral was undisturbed, beating with regularity throughout. A long square anterior flap was made by transfixion over the joint; the muscles and capsule were divided, and a short posterior cut severed the limb. The arteries were tied, sutures in-

sented, and the boy placed in bed. About a wineglassful of blood only was lost.

January 30th.—The stitches were removed.

February 3rd.—The ligatures were removed.

May 16th.—He was discharged convalescent. Three sinuses were together weeping half an ounce of pus *per diem*. The boy looked fresh and well.

February 15th, 1878.—The boy says now that he is quite well; two sinuses are discharging a little, and that little is becoming less every day. He gains weight and flesh.

My finger in the acetabulum readily entered his pelvis during the operation; a loose piece of bone was removed; and this pelvic mischief accounts, in my opinion, for the yet present sinuses.

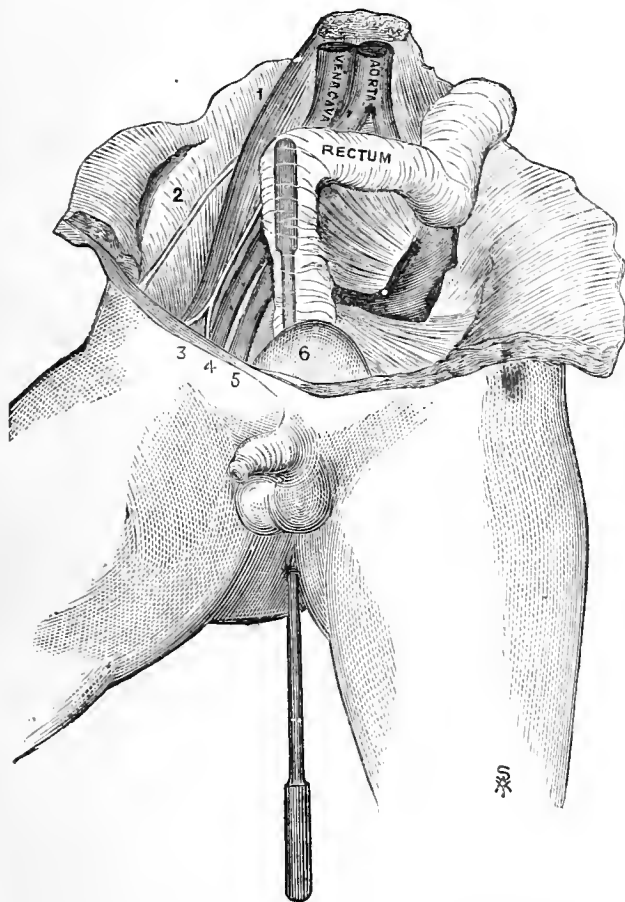

Fig. 1.—The rectum is supposed to be transparent. 1. Psoas magnus muscle; 2. Iliac muscle and exterior cutaneous nerve; 3. Genito-crural nerve; 4. External iliac artery; 5. External iliac vein; 6. Bladder.

In this operation, I have demonstrated that surgeons possess a new method of controlling hæmorrhage; and as an amputation at the hip-joint must ever represent a grievous loss of tissue, any amelioration in its performance must be welcome to the surgeon and the patient. I venture to say that compression of the iliac artery *per rectum* is less serious than compression of the aorta through the abdominal wall; that the former is more *easy and reliable* than the latter, a straight smooth lever alone being required; that the circulatory system is far less disturbed, by reason of the circulation in the opposite limb remaining undisturbed; and no danger results to the rectum from the lever if guided by the hand of an expert surgeon.

[Mr. Richard Davy concluded by demonstrating the operative details on the dead body; and suggested that this new method of compressing the aorta and iliacs might apply to many operations in pelvic surgery.]

M. RICHTER has, he considers, demonstrated that the gastric juice is a combination of hydrochloric acid with tyrosine and leucine. M. Richter's researches bear especially upon the nature of the albuminoid substances in combination with the acid.

## CLINICAL LECTURE

### ON ANTISEPTIC OSTEOTOMY FOR ANKYLOSIS AND DEFORMITY.

By RICHARD BARWELL, F.R.C.S.,  
Surgeon to Charing Cross Hospital.

GENTLEMEN,—Some months ago, I spoke to you concerning the value and use of osteotomy in cases of ankylosis of the knee. I mentioned why, in most cases of true ankylosis at that joint, it would very nearly always be found a most efficient substitute for the more severe operation of excising a wedge of bone from the angle. One of the cases brought to your notice in that lecture, was one of true or bony, the other one of false or fibrous, ankylosis. I now show you a third. A. T., aged 14, also a case of false ankylosis, upon whom I performed osteotomy of the femur very close to the knee, and who has now, you see, a quite sufficiently straight limb, with which he walks very well indeed; the better, too, for possessing a slight amount of mobility at the point of ankylosis. Now, before we go on to another sort of deformity, to which I more especially wish to direct your attention, allow me to say a few words concerning this operation in falsely ankylosed knee-joints. There are very many cases of this sort, in which stretching the fibrous bond with a certain degree of force is the best possible treatment. You have seen me do this a great many times so as to procure a very useful and mobile limb. But there are other cases, like these two, R. B. and A. T., in which the surgeon finds one of two impediments. One is produced by extreme and invincible shortening of the posterior crucial ligament, which causes, if the surgeon wrongfully persevere, posterior luxation of the tibia, partial or total, while extension is produced; the other obstacle only arises when the joint has been more disorganised than in the above event, so that throughout what was its whole, or nearly its whole area, fibrous or fibro-cartilaginous bonds unite the bones. If these bonds be fairly long, the knee may simply be put straight by manual power; but if they be short, and if the shape of the joint-surfaces be much altered, considerable force will be necessary, and this force is in such cases extremely likely so to rend the union that a knee movable in all directions—a flail-joint as it is called—will result. This joint on the knee is very useless, or worse. Therefore when, the patient being narcotised, the surgeon meets with such difficulty, that either one or the other of these misfortunes appears imminent, it is wise to abstain from further effort, and to divide the femur as close as he can to its lower end, either then or on some future occasion. The result will be a rapid and safe convalescence, and an extremely good limb quite sufficiently straight and with a certain, perhaps a very useful, amount of mobility at the knee. Thus much I have felt it right to add to the subject of my former lecture. We will now turn to another class of deformity.

Rickets produces certain curves of the bones which, if they persist, are extremely ugly and detrimental. I say if they persist, because it is desirable to guard against the notion that I would advocate operative interference during early childhood, or while there is a fair chance of spontaneous recovery—for a certain number of young people do recover even from pretty severe distortion of the bones, if they can be placed in the best circumstances for such cure to take place. But a large number of such children, especially after a certain age, do not recover, but must remain permanently distorted, unless operative surgery intervene. The cases which I will show you immediately are not the first cases of rickety distortions remedied by surgery, though one of them offers the largest results hitherto attained or attempted. In 1861, Billroth operated on a bent tibia, and has since repeated the procedure (Langenbeck's *Archiv*, vol. i, p. 677); and, in 1874, Mr. Howard Marsh published in the *Medico-Chirurgical Transactions* three cases in which he had partially divided the tibia with the saw and had fractured the fibula, and one case in which he had removed from the tibia a wedge-shaped piece of bone, a very severe operation unlikely to be repeated.

A few words concerning the *rationale* of the method which I practice may be desirable. My mode of carrying it out you have witnessed. It will be seen at once that, if a bone abnormally bent be

divided, and then placed in a straight position, there must result at the place of division an angular interval between the ends of the bone; that is to say, the two flat surfaces caused by the division will not be in contact throughout, but will only touch each other at one side or corner, while the rest will lie apart more or less according to the amount of rectification which the limb required; and it must of course happen that the interval will correspond with the concave side of the faulty curve.

The problem to be solved is so to arrange matters that this in some cases tolerably wide gap between the bone-ends may be most readily and certainly filled up; and I need hardly say that this will occur if we can leave the periosteum over this gap either entire or very nearly so. The weapon which I use is the chisel. I have no hesitation in saying that this is the best instrument for several reasons; one is the absence of detritus, the other the less injury done to soft parts. Let us for a moment consider what the saw must do to the tissues in the immediate vicinity of a cylindrical bone, one, namely, whose section would be of a circular form. The instrument must have a certain play beyond the edges of that bone, and must, therefore, make in its neighbourhood a quadrilateral wound of a size larger than the tangential square, and this wound not cut clean as with a knife, but mangled throughout by the teeth of the saw. I use, then, the chisel (first employed by Billroth) and, through the same periosteal wound, cut in all directions, but not quite through the bone. I believe practice has given me the capability of judging, partly by distance, partly by sense of resistance, and partly by the sound elicited, when I have reached to very near any of the surfaces. There I stop, and I believe can always avoid going through and cutting the periosteum. The rest of the bone is broken, but even in this simple matter there is a certain method. Firstly, the power must be applied in a direction away from the place where the chisel entered; secondly, the jerk though sharp must be very short, the bone moved but very little away from its natural position. Then the rectification must be done slowly and with a slight amount of extension, not for fear of riding (I have never seen such displacement), but simply to obviate tearing the periosteum.

We will go on to the consideration of cases.

E. B., aged 9, a strong looking handsome child, who has been brought up in a healthy house in the country, was sent to me in October 1877, her mother begging that I would do something to put her legs straight. The condition was then, as you see, very ugly. (Fig. 1.) The bones were well consolidated; and, I think, there was no chance of their getting straight without operation. Accordingly—

October 25th—I divided the right fibula on a very oblique line backwards and upwards, so that the ends might ride and obviate, on straightening the leg, separation of the tibia. I then almost divided the tibia from its inner and posterior edge at a right angle with the shaft; the parts left were easily snapped; the leg was slowly straightened, and put up in plaster of Paris: all this was done antiseptically. The plaster supplied, however, was not very reliable. I therefore postponed operating on the other leg.

November 1st.—I performed the same operation on the left side, and treated the limb in the same manner. No fever or pain followed; the wounds were both healed on November 25th, that on the right leg probably a week sooner, but, after dressing it on the 30th, the dressings had not been disturbed. From this date, nothing further is to be said until December 11th, when the child was allowed to get up.\*

\* That the child had not yet been shown at the Clinical Society of London. Certain of the members remarked that she did not walk very well—a defect resulting from the very recent getting up from bed.

but, in a few days, the union was found hardly strong enough to support the weight, and there was a little yielding of the tibia outward.

She was ordered to bed again until January 22nd.

February 1st.—She left the hospital with the limb as now shown, and walking quite well. (Fig. 2.)

I will but detain you with one other case, one in which no fewer than six bones were divided.

E. E., aged 17, an inmate of the Cripples' Home, where she first came under my notice, begging that something might be done to help her. I therefore took her into Hospital on March 27th, 1877. She was fairly healthy, but the strongly bowed legs were a great trouble. She could not walk, since at each step her body had to be thrown over so much that she either fell or was obliged to seize on some support. Crutches, owing to this oscillation, impeded her, and were worse than useless. The plate, as here given (fig. 3), speaks for itself; but it is well to give some measure-

ment as more accurate than mere appearance. When she stood with the inner malleoli in contact, the knees were just over six-and-three-quarter inches apart.

April 12th.—I divided the fibulæ (obliquely), and then the tibiæ about an inch below the head of the one and the tubercle of the other, and then put the legs straight in plaster of Paris. Both limbs were similarly treated.

May 3rd.—Neither pain nor fever resulted from the above operation; there was fair union. I should have operated a week ago on the femora, but that the catamenia, which were excessive, intervened. To-day, I divided both femora above the junction of the middle and upper thirds from the outer side, and put the limbs in plaster of Paris. She was placed on a couch, properly arranged to obviate any necessity for movement.

July 10th.—The plaster was removed; but the union of the left was less strong than the right, and it was placed on a MacIntyre's splint.

July 11th.—The patient got up, and was placed on crutches.

July 30th.—She could walk very well, balancing rather than supporting herself with crutches.

Another patient called her rather suddenly: she was startled, turned quickly, fell, and broke her right thigh obliquely about an inch and a half above the artificial fracture.

The second fracture did not do so well as the one I had purposely made: it was very difficult to prevent the bone from riding, and to keep it straight. The progress was slow, and the result a slight bend forwards of this part, and a shortening, which the original section had not produced.

On December 28th, 1877, she left the Hospital, able to walk well, and with the limbs very fairly straight.

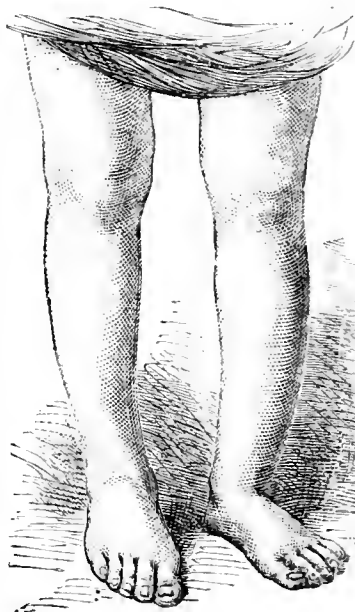

Fig. 2.

Fig. 1.

Fig. 3.

A little examination of the plate (fig. 4) shows that the right femur is more bent than the left—the result of the accidental fracture; and, had this not occurred, there is no doubt that the knees would have been almost, if not quite, in contact. Even as it is, the result is such as to render it doubtful whether she is now a fit inmate of an institution for cripples.

These cases show clearly that osteotomy with the chisel is an operation unattended with danger, with fever, or indeed with more than very trifling pain; by its means we can rectify deformities and lameness, hitherto considered beyond the reach of art; and, as in the case of ankylosis, may substitute a very mild operation for one greatly more severe. In none of the many cases on which I have performed this operation has the fracture suppurred or inflamed, but the bones have united with remarkable rapidity, even when a large wedge-shaped gap must have existed.

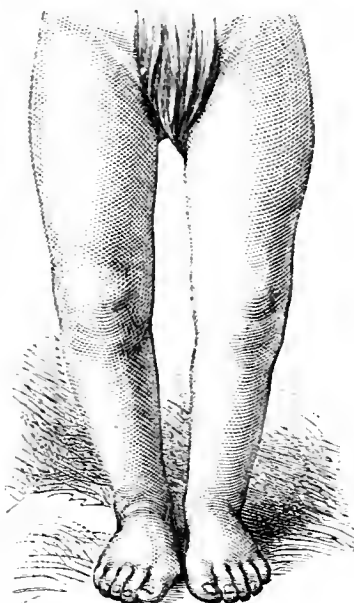

Fig. 4.

[To be continued.]

## CASE OF PARTIAL CONVULSIONS (JACKSONIAN EPILEPSY); WITH OBSERVATION ON PERCUSSION OF THE SKULL IN DIAGNOSIS.\*

By ALEXANDER ROBERTSON, M.D.,

Physician to the Town's Hospital and City Parochial Asylum, Glasgow.

I SHALL first record this case, and afterwards direct attention to its points of special interest.

J. N., aged 38, engineer, while in Madras, in 1868, had sunstroke. Previously, and also after its occurrence, he was of drunken habits. In 1869, he had syphilis—a chancre on the penis, followed by indolent bubo in the groin, and a severe and protracted attack of pains in the joints and bones, which were worse at night. There is not, however, any history or existing indication of nodes, nor are there any glandular enlargements, and he has a healthy aspect. About seven years since, he began to suffer from seizures of an epileptiform character, recurring every six weeks or two months, but latterly at rather shorter intervals. These have occurred in different forms; but the following has, upon the whole, been the most frequent. Spasmodic action, usually without premonitory symptoms, begins in the right hand as a whole, though, in a number of instances, it has begun in the little finger; then the hand becomes clenched and bent at the wrist, the forearm is flexed on the arm, and the head is drawn towards the right shoulder. The arm, in this contracted state, is then jerked across the breast for about a minute, after which the attack ceases. Consciousness is not impaired during the whole time. On a number of occasions, the convulsive seizure has been limited to the right lower extremity; beginning in the right foot, extending thence upwards to the thigh, and ending in forward and backward movements of the leg, which lasted for some minutes. At other times, however, and more frequently of late, the attacks, beginning in the arm and progressing as described, have extended to the side of the body and right leg, and have advanced to unconsciousness. When this happens, the last event he is aware of is the forearm turning outwards from the chest and becoming supinated. So far as can be ascertained, the convulsive action seldom affects the left side. The succeeding unconsciousness may last a quarter of an hour or even longer. All the fits are accompanied by severe pain in the convulsed members. They are also followed by more or less of paralysis in the same parts, which, however, does not generally last above three or four hours, and

may pass away in a much shorter time should the preceding convulsions be slight.

On September the 24th, he had a severe fit. The convulsions were stated by an intelligent patient beside him to have lasted about three minutes, and the unconsciousness about ten minutes. I saw him just after he had become fully conscious, and proceeded to test the motor power and the sensibility in the extremities which had been convulsed. The following notes were then made. At twenty minutes after the fit began, when I placed my fingers in his right hand and asked him to squeeze them, no appreciable pressure was felt on his attempt, while the pressure with the left hand was moderately firm; at thirty minutes (tested by dynamometer), pressure by the right hand two pounds, left hand thirty-five pounds; at fifty-five minutes, right hand twenty-six pounds, left thirty-seven pounds; at two hours, right hand fifty-four pounds, left fifty-one pounds. The patient is right-handed. At twenty minutes, he could scarcely raise the right leg from the bed; but after that, power was restored to it nearly *pari passu* with the arm. At twenty minutes, he scarcely felt sharp pinching in either the right upper or lower extremity; at thirty minutes (tested by aesthesiometer), both on the back and front of the right hand and wrist the two points of the instrument were felt as one at nine inches, whereas on the palm of the left hand the points were felt as two at one inch and a quarter, and at three inches on the back of the same hand; at an hour, on the front of the middle finger of the right hand both points were felt at an inch, and, on corresponding finger of the left hand, at three-quarters of an inch—sensation being all but fully restored in the affected hand.

Some months ago, I happened to be in the ward, when he had a seizure with very different features from those hitherto described. He began to cry out in a mournful strain, "Oh dear! oh dear!" and, on my going up to him, he asked me, with a wild frightened aspect, what was going to be done to him. In about half an hour, he regained his mental composure. There were no convulsive movements. He states that previously he had suffered from three other such turns.

He is of average intelligence; and, in illustration, it may be mentioned that he has the charge of the galvanic batteries in the hospital. He states, however, that his memory is rather impaired. He does not suffer from headache, but, on tapping somewhat firmly with the point of the finger all over his head, he feels pain of moderate severity on the left side, above the centre of the left ear, over a nearly circular area two inches in diameter. The lowest part in the circumference of this space is two inches above the highest point of the ear. He was not aware of any pain or uneasiness in this region till his attention was directed to it by the percussion. There is no indication of any other impairment of nerve-function, except a little deafness of both ears, probably due to his occupation, and a just appreciable greater width of the right pupil than the left one. The retinae are normal in appearance.

The treatment has consisted chiefly in the administration of the iodide and bromide of potassium. He is at present getting the iodide in thirty-grain doses, twice daily. Besides, since the discovery of the local pain, which is only lately, the first of what is intended to be a succession of blisters has been applied over the affected region.

REMARKS.—1. The lesion is probably situated on the surface of the brain, involving the inner membranes, in the area corresponding with the dull pain, and thus implicates the motor region for the extremities, as indicated by Hitzig's and Ferrier's experiments.

2. Percussion of the skull was of material aid in the diagnosis. By this mode of examination, namely, smart tapping by the finger, the force applied may apparently be transmitted to the membranes and surface of the brain, to such a degree as to induce pain in these parts, if they are in a morbid condition. Obviously this test will more likely be of service when the disease is circumscribed than when it is generally diffused. It is worthy of note that, as no pain is felt till the part is percussed, probably the lesion does not implicate the skull, or the skull and dura mater; for when these parts are involved, and particularly when syphilis is the cause, the pain at the affected points is usually distinct enough, especially at night, and indeed is often very severe.

3. The starting-point of the morbid action inducing the fits would seem to have been sometimes in the centre for the arm, at other times in the centre for the leg, and occasionally in that for purely mental function.\* This suggests the propriety of not too hastily arriving at a conclusion respecting the limits of a lesion, by reason of the convulsive movements occurring in the same order in two or three successive fits.

4. The paralysis which followed the convulsions, though at first very complete in degree, was of brief duration; and is explained in accordance with the view now being generally accepted, that this form of palsy is due, not to organic change, but rather to temporary exhaustion

\* In a paper published in the *Edinburgh Medical Journal* for December 1874, I directed attention to this occasional varying mode of commencement of the fits in the same patient.

of the nerve centres, and perhaps also, I would add, of the nerves involved. It apparently corresponds with the transitory paralysis induced by physiologists in the lower animals, by passing a strong galvanic current through the spinal cord or motor nerves; or, in a minor degree, with the fatigue that follows unwonted and excessive voluntary muscular exercise.

5. It seems probable, from the fact that the severe pain which accompanied the convulsions was followed by ephemeral anaesthesia in the affected members, that the centre for sensation, and possibly also the corresponding sensory nerves, were in a state similar to those for motion. This association is analogous to what is observed in hemiplegia due to organic lesion, and, just as in it, the sensory defect was even of shorter duration than the loss of motor power.

6. It is worthy of being recalled that analogues of convulsions with excessive pain, followed by temporary palsy and anaesthesia, exist in the sphere of special sensation, as in a case recorded by me in the BRITISH MEDICAL JOURNAL (April 18th, 1874), in which, at the beginning of an epileptic seizure, a ball of red fire was seen by the patient, who for some hours afterwards was unable properly to recognise that colour. And I think we also see an analogous condition in the sphere of mind in the degree of dementia which ordinarily follows an attack of acute mania before restoration of full mental power.

## ON THE TREATMENT OF PUERPERAL HYPERTYREXIA BY COLD.

By ALFRED WILTSHIRE, M.D., F.R.C.P.Lond.;

Joint Lecturer on Midwifery and the Diseases of Women and Children at St. Mary's Hospital; Vice-President of the Obstetrical Society of London.

DR. PLAYFAIR'S case of puerperal septicæmia, with hyperpyrexia, treated by the continuous application of cold (recorded in the JOURNAL for November 17th), opens up for discussion the practice of treating such cases by the rapid abstraction of heat, a remedy which has proved of inestimable value in other grave maladies accompanied by hyperpyrexia. As I am able to contribute particulars of two cases similarly treated by a method which appears to possess some advantages, I avail myself of the opportunity now afforded by Dr. Playfair's communication to lay them before the readers of the JOURNAL.

The cases were briefly narrated at a meeting of the South-Eastern Branch on December 9th, 1875 (see the JOURNAL for December 25th, 1875); but no particulars have until now been published.

In the autumn of 1873, I succeeded my friend and colleague Dr. Edis in the charge of the in-patients of the British Lying-in Hospital, an institution to which I was then physician. In giving the patients into my charge, Dr. Edis remarked that there was something wrong about the place; for none of the mothers had a temperature under 100 deg. Fahr., upon which I observed that I should feel compelled to close the hospital, if things continued in an unsatisfactory state. I regret to say that closure immediately became necessary, on account of the serious symptoms which arose in two newly admitted patients.

A day or two after I took charge, two healthy young women, primiparæ, were delivered in the hospital. Both were married, were aged respectively 23 and 26, and had fairly good labours, there being nothing abnormal in either case. I had the temperature watched, as has now for many years been my custom, and very speedily it attained high figures. There was no local condition in either case to account for this abnormal elevation of temperature, and it appeared to be only too clearly due to the unhealthy surroundings of the patients. Finding that quinine in large and repeated doses, intra-uterine irrigations, purges, and so on, were ineffectual for the reduction of the excessively high temperature, which in each case exceeded 106 deg.; and feeling persuaded that such hyperpyrexia was incompatible with life, if long-continued, I had the patients packed round with vessels containing ice; hot water-tins, soda-water and other bottles, being filled with broken ice.

This dry cold method was selected because it obviated the necessity of removing the prostrate patients from their beds: a point which has always seemed to me to be of much importance in the treatment of hyperpyrexia by cold, since the patients for whom it is necessary are usually extremely exhausted. The temperature in each case was promptly reduced, but it rose again, after a variable fashion, when the cold was removed, and occasionally, I am bound to say, apparently in spite of it. Still, in the main, when it was carefully and assiduously applied, the effect of this method of reducing temperature was distinct, and the relief experienced by the patients was at times great and palpable. The only inconvenience arising from its use was the inability of the patients to sleep during its application. Chilling of

the skin appeared to be attended by increased vascular supply to the nervous centres, and consequent wakefulness. This might doubtless have been obviated if we had then had at command the efficient means we now have for cooling the head; viz., the ice-cap. As it was, sound sleep speedily followed the removal of the cold; the cerebral vessels being obviously relieved by the flushing of those of the skin. For many days, a weary fight was kept up with fluctuating success, the temperature occasionally remaining normal for several hours. Ultimately, one of the patients recovered, and the other, to my great regret, sank. Unfortunately, no necropsy was obtainable.

I believe that, could we have removed the patient whose case ended fatally from the building, she also would have recovered; for, again and again, her temperature fell to normal or near it, and she appeared to be on the verge of convalescence; she seemed, however, to get fresh doses of poison and relapsed accordingly. What tends to confirm this view is the fact that the other patient, who oscillated in like manner, only recovered on being removed, though at some risk, to her home at Croydon. In neither case was there any purulent collection or other abnormal condition, except that, in the one that ended fatally, there was at one time slight tenderness of the uterus. Both were what might be called ichorrhæmic cases; they were poisoned by their environments, the poison exerting in them powerfully phlogogenic effects. This is by far the most fatal form of "puerperal fever"; in my experience, it is much more rapidly and certainly fatal than where "puerperal fever" is accompanied by suppuration.

Some weeks afterwards, on attending a meeting of the South-Eastern Branch at Croydon as the guest of Dr. Alfred Carpenter, I found the surviving patient in the Croydon Hospital, whither she had been taken shortly after her removal to her home. Her appearance interested me greatly; for, from a plump blonde with plenty of fair hair, as she was when I first saw her, she had changed to a thin dusky-skinned woman with scarcely any hair. Her appearance showed plainly the severity of the struggle she had gone through: her epidermic structures generally had withered, as usually happens after *post partum* inflammations.

In both the cases just related, the skin was occasionally sponged with cold water. There was one noteworthy difference between them, inasmuch as only one of the patients perspired, and that was she who recovered. The other's skin was obdurately dry, and it is obvious that her power of radiating heat was correspondingly diminished. Efforts were made to induce sweating, but unsuccessfully. Her friends said they had never known her to perspire.

The advantage of applying cold to hyperpyretic patients without moving them is obvious. It is especially useful, for example, in acute articular rheumatism, and in cases of typhoid fever where perforation of the bowel from ulceration is dreaded, since movement from the bed to a bath, or *vice versa*, might precipitate bursting. This plan has already been attempted with partial success by wet packing and so on; but the packing around with vessels containing ice in addition to the wet sheet or sponging appears to be a ready and powerful means of abstracting heat without unduly disturbing the patient.

Besides its value in puerperal cases, as illustrated by Dr. Playfair's case and by the foregoing, I have also found it of great value after ovariectomy. During the past year, I used it in conjunction with another and similar method, also very valuable—the ice-cap—in, among others, two cases of ovariectomy at the West London Hospital. Both patients recovered, and I believe they owe their recovery in no small degree to the prompt abstraction and subsequent control of heat by the continuous application of cold.

My own observations enable me to concur fully in the opinion that the control of abnormally high temperatures by the application of cold is not only largely feasible, but that it is a therapeutic agent of immense value in a great number of cases. I mean that, by the rapid reduction of hyperpyrexia, not only do we remove excessive and dangerous heat, but also that probably we, at the same time, hinder its production: a result of enormous importance. I am, therefore, quite at one with those who consider that we ought not to wait for *foudroyant* manifestations of hyperpyrexia, but that alarm should be taken early, and efforts made, if possible, to suppress its genesis. There are doubtless still unused methods of doing this, and it will well repay those who are called upon to employ cold to devise means suitable to different cases. For example, where the patient can bear removal from the bed to a bath of cool water without risk, nothing can be better; but numbers of patients could only be so moved at great hazard, and then such measures as water-beds and cushions filled with cold water, vessels containing ice, ice-caps, sponging with cold water, wet packing, exposure to cold air, and so on, might be adopted. Wet packing may, in a modified way, be advantageously combined with ice-packing; and, as both are applicable without undue disturbance of the patient, they are

valuable auxiliaries in cases of marked prostration. Moistening the skin and allowing free evaporation not only favours the radiation of heat, but is also extremely grateful to febrile patients. I have adopted the combined plan with decided advantage.

I have more than once stated, at the Obstetrical Society and elsewhere, that quinine appears to exert much less influence over hyperpyrexia of ichorrhæmic origin than over that associated with, if indeed it be not dependent upon, suppuration; and I would venture to suggest the probability that the ichorrhæmic cases which show the highest temperatures and are the most rapidly fatal may be more favourably influenced, if not entirely controlled, by the assiduous application of cold than by the administration of quinine, valuable as that drug doubtless is in other cases. The brilliant results which have attended the administration of salicylic acid and its salts in acute rheumatism, usually a non-suppurative disease, lead one to hope for similar results in puerperal septicæmia unaccompanied by suppuration. I cannot forbear remarking that our present therapeutical resources encourage the belief that we are better able to cope with "puerperal fever" in its various forms than heretofore, more especially when their employment is not unduly delayed.

It only remains for me to say that the further admission of patients into the hospital was immediately suspended on the appearance of unfavourable symptoms in the two patients whose cases I have just related; and that, on inspection, quite enough was found to account for the unhealthy state of the building. Thorough measures were resorted to with marked success, and the recommendation that the hospital should be closed periodically for thorough cleansing and disinfection was adopted by the authorities. This plan has been attended by marked success; and I learn from the matron (Mrs. Freeman) that, at the present time, the condition of the patients is most satisfactory, although other metropolitan lying-in hospitals are not so free from mischief as could be wished. The acting matron (Mrs. Thompson) deserves a warm acknowledgment of the intelligent skill with which she attended to the two patients whose cases are related above.

## TWO CASES OF HYPERPYREXIA TREATED BY THE COLD BATH.

By A. T. H. WATERS, M.D., F.R.C.P.,  
Physician to the Liverpool Royal Infirmary.

THE following cases may perhaps be considered worth publishing. Their publication has been delayed by the unsuccessful endeavour to recover the lost notes of a third case—one of typhoid fever—treated on similar principles.

CASE 1.—I was summoned on May 15th, 1876, to see a patient who was under the care of Dr. Johnstone of Upholland, and it is with his consent that I publish the case. The patient was a married lady twenty-six years of age, of strumous aspect, suffering from an attack (the first) of acute rheumatism, with pericarditis. Her attack had commenced on May 8th, and she was first seen by Dr. Johnstone on the 10th, when the temperature was 104 deg. During the four following days, the temperature, when taken, ranged between 104 deg. and 105 deg. I saw the patient at 5 P.M. on May 15th, about the eighth day. The case was one of severe rheumatic fever, and the physical signs of pericarditis were well marked. The patient was restless, but free from delirium. The pulse was 120, and the temperature 104.2 deg. The urine was very acid. The treatment which had been adopted by Dr. Johnstone was the administration of bicarbonate of potash, with bark and opium, and four ounces of brandy daily. I recommended that the treatment should be continued; the dose of potash, however, to be increased, and that of opium diminished. I further advised that, should the temperature rise to 106 deg., the patient should be put into a bath at 95 deg., to be cooled down to 75 deg. or 70 deg. On the following day, at 1 P.M., Dr. Johnstone found the temperature 106.2 deg., accompanied with "furious delirium". Dr. Johnstone says: "I had her put into a bath (tepid), which was quickly cooled down to perfectly cold. (I cannot give you the temperature, but the water was cold from the pump.)" The patient was in the bath half an hour. The delirium sensibly decreased during this time. She slept a little the night after the bath, and, on the following day, she slept profoundly for two or three hours, and after this there was no delirium. At 10.30 P.M. of the 16th—viz., between eight and nine hours after the bath—the temperature was 102.6 deg. On the 17th, at 9 A.M., it was 103 deg.; at 3.30 P.M., 102.8 deg.; and at 10 P.M. 102.8 deg. Dr. Johnstone says: "Beyond this, I have no further record. I can only say that her progress towards recovery was

uninterrupted. She left home about the end of June for the seaside, feeling perfectly well, but with a slight systolic murmur."

CASE II.—E. W., a domestic servant, nineteen years of age, was admitted into the Liverpool Royal Infirmary, under my care, on November 21st, 1876, suffering from typhoid fever. She had been confined to her bed for about a week, but had not been under medical treatment. There had been slight looseness of the bowels, but no decided diarrhoea. She was ordered milk and beef-tea, and effervescent mixture, three times a day. On the morning of the 22nd, the day after admission, the temperature (then and afterwards taken in the axilla) was 101 deg., and in the evening 104.6 deg. On the 23rd, it was 101.8 deg. in the morning, and 104.6 deg. in the evening. Three ounces of brandy were ordered on this day. On the morning of the 24th, at 9.30, the temperature was 105.6 deg.; at 12.15, 106.4 deg.; and at 12.45, when I paid my visit to the hospital, it had risen to 106.8 deg. There was no delirium; but the patient was restless. Being unable to remain at the Infirmary, I gave directions that the temperature should be taken every quarter of an hour, and that, if it rose to 107 deg., the bath should be used. At 1.15, the temperature was found to be 107.2 deg., and the patient was put into a bath at 100 deg., which was gradually reduced to 75 deg. The patient was in the bath an hour and five minutes, and on removal her temperature was 99.6 deg. At 3 P.M., ten grains of quinine were given, and were vomited; at 3.35, five grains were given, and retained. The temperature began to rise soon after the bath, and at 5.15 it was 105.6 deg., and the bath was again used; the temperature of the water being 99 deg. at the beginning and 76 deg. at the end. The patient was in the bath an hour, her temperature on removal being 100.8 deg. At 6.30, five grains of quinine were given. The temperature again rose after the second bath, and at 8.15 it was 103.8 deg.; and the house-physician thought it best to use the bath again. The patient remained in it half an hour, the temperature of the water being 97 deg. at the beginning and 76 deg. at the end. On removal, the patient's temperature was 99.8 deg. She was put to bed, and I saw her immediately afterwards, and ordered five grains of quinine to be given every four hours. She slept during the night, and, at 9.30 A.M. on the 25th, the temperature was 99 deg. and the pulse 100. She had perspired freely, and had taken six doses of quinine, with a good deal of milk and beef-tea, and nine ounces of brandy, since the first bath. The quinine was now ordered to be taken every six hours. The highest recorded temperature of this day was at midnight; viz., 104.2 deg.; but it soon fell, and, at 9 A.M. of the 26th, it was 100.4 deg., and in the evening 102.4 deg. On the 27th, great pain was complained of in the left side; but no signs of pleurisy or any inflammation could be detected. The pain continued for some days, and was relieved by subcutaneous injections of morphia. The quinine was diminished, and the patient took nothing but milk and beef-tea, with a moderate quantity of brandy. There was no diarrhoea throughout, and only a few characteristic spots appeared. For a few days, the temperature remained very moderate, and there was no complication; but, on the evening of December 2nd, the temperature was found to be 104.8 deg., having risen from 99 deg. since the morning. The patient was carefully watched, and five-grain doses of quinine were given every six hours. The temperature soon began to fall, and, on the evening of the next day, it was 100 deg. With the exception of a rise of the temperature to 102.5 deg. on December 10th, and of 103.5 deg. on the 13th, the recovery was uninterrupted. She was discharged from the hospital on January 5th, 1877, the temperature having been normal for a fortnight.

## NOTES ON A CASE OF MULTIPLE EXOSTOSES.\*

By THOMAS JONES, M.B., F.R.C.S.,  
Surgeon to the Children's Hospital, Manchester.

THE condition of several exostoses developed in the same individual is a sufficiently rare occurrence to induce me to place on record the following remarkable case.

Wm. S., aged 9, a native of Warrington, was admitted into the Children's Hospital on July 3rd, 1877. The immediate cause of the parents seeking advice was a large tumour springing from the posterior surface of the right leg about two inches below the knee. This mass, of irregular shape and firm consistence, was found to spring from both bones. The skin over the tumour was of normal colour and freely movable. A further examination of the boy resulted in the detection of a number of bony outgrowths, of various sizes and

\* Read before the Section of Surgery at the Annual Meeting of the British Medical Association in Manchester, August 1877.

shapes, in different parts of the body. They were connected with the following bones: the right clavicle, one at each end; the upper extremities of both humeri; the carpal ends of the right and left radii; the lower ends of both ulnæ; the second phalanges of the ring and middle fingers of the right hand; the outer side of the second phalanx of the middle finger on the left hand; the dorsal surface of the middle phalanx of the left ring finger; the lower border of the same phalanx; the lower ends of both femora; the posterior surface of the right femur; the upper ends of both tibiae; the outer surface of the left fibula; and the dorsal surface of the middle phalanx of the left second toe.

Besides these outgrowths, the upper end of the left fibula and the lower end of the right radius are very materially increased in thickness. I would also mention a deformity of the left ulna which the boy presents. The lower third of this bone appears to be quite in a rudimentary state, and to join the radius, thereby destroying the power of pronation and supination in the left forearm.

The progressive increase in the size of the osseous tumour situated on the right lower extremity rendered its removal advisable. The operation by a single straight incision in the long axis of the limb was performed on July 18th. The fibular attachment of the tumour was much broader and firmer than the tibial. On section, it was discovered that the greater part of the mass was made up of cancellated bone-tissue, and that it was enveloped by a thin layer of glistening cartilage.

The case I have briefly related, while agreeing in many respects with those already published, differs in many particulars. It coincides with the cases referred to in Paget's *Surgical Pathology*, and with Dr. Poore's (*Lancet*, Nov. 29th, 1873), in the tolerably symmetrical arrangement of the growths, and in those on the right side being larger than those on the left; but, unlike these, careful inquiry has failed to establish the presence of any osseous deformities in other members of the family.

I am unable to offer any theory as to the causation of these exostoses. I think, however, I may say with confidence that they were not the result of conditions which are generally looked upon as causes—such as rickets, syphilis, and struma. There is an entire absence of the usual indications of either struma or syphilis, and the conformation of the osseous system in general renders the probability of rickets ever having existed very unlikely.

The local hypertrophy of the right radius and left fibula appears to lend some countenance to the observation made by Sir James Paget, that these exostoses are to be regarded as closely related to osseous malformations by excessive development.

In conclusion, I would submit that the formation of a number of bony tumours in connection with the osseous system should be looked upon as evidence of a constitutional ossific dyscrasia.

## SURGICAL MEMORANDA.

### ON TREATMENT OF FRACTURE OF BOTH BONES OF THE LEG.

I beg to offer a suggestion in the treatment of fracture of both bones of the leg. We have all noticed the difficulty of keeping the inner edge of the patella in a line with the great toe; that is to say, after the bones have been carefully set in the straight position with the inner edge of the patella in a straight line with the great toe, after the lapse of a few days the patella is more to the outer side than it should be, in consequence of the external rotation of the leg from the hip. My plan of treatment is to set the limb in the straight position, to swing it in one of Salter's cradles, and then to rotate the whole limb outwards. The advantages of this treatment are: 1. The greater comfort of the patient, as it is the natural position of the limb; 2. The prevention of that rotation at the seat of fracture which ends in the turning in of the foot after cure.

J. B. RICHARDSON, M.B. (late House-Surgeon Torbay Hospital), Lynsted, Torquay.

### CATGUT LIGATURES AND DRAINS.

It is not my purpose to open up a discussion with Mr. Lane upon the fitness of catgut ligatures; but I must crave permission to make a brief statement upon a question of fact. In calling my description of the state of the vessel ligatured, as revealed *post mortem*, "very singular," Mr. Lane seems to throw some doubt upon its accuracy. May I, therefore, be permitted to state that the artery was exactly as I described—"cut through, with the exception of a short interval about a

line in length"? On referring yesterday to the *post mortem* record of the case made by the pathologist to the infirmary, Dr. James Ross, I find, indeed, that it is spoken of as if completely cut through; but this was not the case, as I found on demonstrating the specimen to my class in practical surgery at Owens College. In the same record, indeed, I find that a loose and soft coagulum is mentioned as being present on the proximal side; but Dr. Ross told me yesterday he regarded this as a *post mortem* clot, and in this opinion I concur. That the ligature was properly tied, we had evidence in the absence of the radial pulse for two days; its reappearance at this date being, I think, due to a yielding of the ligature and a re-establishment of the through current of blood. The reason that no violent hæmorrhage took place before death was doubtless due to the fact that the external wound had nearly healed; and there was much firmly organised lymph around the vessel, forming, for the time at least, an efficient barricade.

S. MESSENGER BRADLEY, Manchester.

## THERAPEUTIC MEMORANDA.

### ERUPTION AFTER BROMIDE OF POTASSIUM.

REFERRING to Dr. W. Russell's interesting case of bromic eruption controlled by arsenic (*BRITISH MEDICAL JOURNAL*, March 16th), I would point out that Bartholow says: "Bromic acne may be, in part at least, prevented by the conjoined administration of arsenic" (three to five minims of liquor arsenicalis) (*Materia Medica*, p. 371), and I have verified this several times. It deserves still further inquiry, and the influence of arsenic itself over the nervous system is such as to make it, for its own sake, a most useful adjunct to treatment by the bromides in many cases, e.g., of cerebral or spinal congestion.

EDWARD MACKAY, M.D.

## OBSTETRIC MEMORANDA.

### INTRODUCTION OF THE HAND INTO THE UTERUS AND REMOVAL OF THE PLACENTA, SIX WEEKS AFTER DELIVERY.

IN none of the cases quoted by Dr. Matthews Duncan, in his recent paper on the subject (*BRITISH MEDICAL JOURNAL*, November 1877), was the introduction of the hand into the womb, practised at nearly so long an interval as six weeks after the expulsion of the child.

During my absence from home on December 11th, 1875, Mrs. L., aged 25, and mother of three children, began to abort at the middle of the fifth month, and during the night was delivered, without assistance, of a well-formed male child of that term. My friend Dr. St. Clair, who saw the patient for me, three hours after the child had been born, was unable to remove the placenta, owing to the obstinate refusal of the patient to submit to interference. On my arrival next day, twelve hours after the child had been expelled, I found the cervix unusually long and the os firmly contracted; but, from the size of the womb, I concluded it still enclosed the placenta or a large clot. There was then no doubt in Dr. St. Clair's mind that the placenta was still *in utero*; but there was, he said, a possibility that it had come away, as at least one vessel had been emptied without his inspection. All efforts, then, within the bounds of legitimate force, only proved the futility of further attempts to reach the interior of the womb. Nothing then was to be done, but to wait and watch for symptoms. So things went on from day to day and from week to week until, at last, I began to think that the placenta must have been removed unnoticed, or, disintegrated, had come away in the discharges, which all along had been considerable. The possibility of its being absorbed was also suggested. During this time of considerable doubt and no little anxiety, I sought and availed myself of the kind and valuable counsel of several friends. The patient gained in strength, and there was not an unfavourable symptom; but the abdomen increased in size, and the patient herself imagined that she was still pregnant with a second child. While I was with her, however, on January 22nd, 1876, a gush of blood poured from her without warning, saturating her clothes and the bed on which she was lying. With ergot, and by using my finger as a plug in the os, which was dilated to about the size of a sixpence, I endeavoured to control the flooding, and as quickly as possible got the patient under chloroform, introduced my hand into the vagina, and with great difficulty dilated the os until at length I got my whole hand into the womb. There I found a large placenta, only partially, for about one-third of its surface, detached from the uterine wall; the remainder I peeled off

and slowly withdrew the whole mass. The uterus contracted immediately and the hæmorrhage ceased. The patient, naturally of a delicate constitution, made a rapid recovery. The placenta, when removed, was perfectly fresh, well nourished, and measured four and a half inches in diameter.

LESLIE JONES, B.F., M.D., M.Ch., Blackpool.

#### RETENTION OF THE PLACENTA AFTER ABORTION.

IN THE JOURNAL for May 4<sup>th</sup>, under the heading "Obstetrics", Dr. Hervieux reports a case of retention of placenta in the uterus for twenty-one days after an abortion at the sixth month. This reminds me of a case which happened in my practice some years ago, a short account of which may be interesting.

I was called to see a lady who was in the fourth month of her pregnancy, and who was suffering from severe hæmorrhage, which was so profuse that I was obliged to plug the vagina. She aborted at the fifth month; but the placenta resisted all justifiable means for its expulsion. She convalesced in the usual time; but, as the placenta was still retained, I obliged her to keep the recumbent position. She continued perfectly well; and, in thirty-eight days after she aborted, the placenta was expelled during the action of some purgative medicine which I found it necessary to give her. The placenta was small, healthy, and without a trace of fœtor.

RICHARD STANISTREET, M.D., L.R.C.S.I., Malahide.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN AND IRELAND.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### CONSULTATIONS.

**APRIL 25TH.**—*Large Abscess of Thigh, etc.*—A man, aged 64, but looking much more aged, had been admitted into Harley ward eight weeks previously. He had been unable to pass his urine without difficulty, and had been under the care of a surgeon for some weeks, during which period he suffered from constant pain on the inner aspect of the left thigh. On admission, there was a large fluctuating swelling at the seat of pain, extending from about half way down the front aspect of the thigh downwards and inwards as far as the popliteal space. Fluid could be detected in the left knee-joint. The urine was turbid, of neutral reaction, and slightly albuminous. The difficulty in micturition appeared to have been due to atony of the bladder. The swelling was punctured, and a large quantity of creamy pus escaped, mixed with blood and old clots; the femur was found to be denuded of periosteum. The patient rapidly lost flesh, and the abscess-cavity continued to discharge, the temperature persisting at from two to three degrees above the normal point. This case was brought forward by Mr. Callender, who was ready to perform amputation if his colleagues thought it would increase the slender chances of recovery which the patient had. None, however, were in favour of the operation, which, it was considered, would only hasten death, already only too near at hand.

**May 2nd.**—*Large Nævi of Forearm.*—Mr. MARSH brought into the operating theatre for consultation a child two years of age that had been born with a large subcutaneous naevoid tumour above the back of the wrist, another on the back of the forearm below the olecranon, and another on the front of the arm immediately above the bend of the elbow; all these growths were on the right upper extremity. The lowest had distinctly naevoid characters from the first; the others had of late developed more definite naevoid features than they possessed when they were first examined, and the cutaneous vessels over them were enlarged. During the last few weeks, the lowest had, rather suddenly, become larger, firmer, very smooth and globular, and the integument over it was very red. Mr. Marsh believed this lower tumour to be a suppurating naevus, and proposed to explore it; but thought it within the range of possibility that the growth might be malignant.—Mr. CALLENDER felt tolerably certain the tumour was naevoid, and recommended an exploratory incision. The suppurating was beneficial, and would ultimately cure the naevus.—Mr. THOMAS SMITH and Mr. LANGTON were of the same opinion as to the nature of the disease; they recommended expectant treatment, as the inflam-

matory changes would most likely cure the naevus and render exploratory incisions unnecessary.

*Swelling of the Forearm.*—Mr. THOMAS SMITH brought forward a young man who had been troubled for a year with a general, firm, ill-defined swelling of the forearm. Mr. Smith, judging from the general characters of the disease, stated that either a large tumour of one of the bones of the forearm existed, or else there was diffused chronic periostitis and osteitis. The latter was the more probable. Mr. Smith proposed to keep the patient at rest for a few weeks, giving a trial to various drugs, and if no improvement resulted to make an exploratory incision which would let out pus, if any were pent up under the periosteum.—Mr. CALLENDER also believed there was inflammatory mischief in the bones from some injury, which had either torn the muscles from their periosteal attachments, or bruised the bone itself.—Mr. LANGTON could detect, on pressure, deep-seated fluctuation in the part.—All the surgeons agreed to Mr. Smith's proposed line of treatment.

*Injury to Urethra: Stricture: Extravasation.*—Mr. CALLENDER desired to consult the opinion of his colleagues on a case of great interest in Harley ward. A man, aged 32, had fallen, six years ago, astride over the bulwarks of a barge on board which he was working. He felt no ill effects till a few days later, when he passed blood with his urine. A stricture ensued and gave him great trouble. On Jan. 23rd of this year, he was admitted into the hospital with extravasation of urine. Free incisions were made into the groin and scrotum, and much inflammation followed. Many attempts had been made to pass a catheter, but the smallest were stopped close to the membranous part of the urethra by a stricture which appeared to be impassable; or, possibly, the instruments entered an old false passage running in the normal line of the urethra. The patient can at present pass a little urine by the meatus, but most of that fluid escapes during micturition through large sinuses in the scrotum. The urine had been constantly slightly albuminous during his stay in Harley ward; and his health had been in a bad condition for some years. Taking all the untoward circumstances of this severe case into consideration, Mr. Callender believed that it would be advisable to open the bladder above the pubes and let the urine escape for a time through a catheter inserted in the wound, so that the urethra might be kept well at rest. Then, when the local mischief had subsided, he would pass a catheter from the vesical orifice of the urethra and would introduce another by the meatus, and, with the instruments as guides, he would finally be enabled to lay open the stricture. This plan, originally suggested by Hunter, had been successfully adopted by Mr. Callender in a case recorded in the second volume of the *Saint Bartholomew's Hospital Reports* (On an Operation for the Relief of a Stricture of the Urethra).—Mr. LANGTON approved of the proposed treatment. In a similar case, he had opened the bladder above the pubes and retained a catheter there for some time. The patient is now in China in perfect health. He continues to pass urine by the suprapubic incision, which is closed by a plug during the intervals between micturition.—Mr. MARSH, also, was in favour of Mr. Callender's proposal, especially as his previous case had been so satisfactory; and, on the other hand, the state of this patient's health contraindicated urethrotomy or perineal section.

#### KING'S COLLEGE HOSPITAL.

##### CASES OF CHEST-DISEASE.

(Under the care of Dr. BURNEY YEO.)

*Pleuripneumonia supervening upon diffused Bronchial Catarrh (? Catarrhal Pneumonia): Exploratory Puncture.*—J. G., a man aged 31, was admitted to hospital, March 8th, suffering from an acute illness of four days' duration. The onset had been sudden, with shiverings, soon followed by urgent dyspnoea. He had always had a cough, which had been much worse during the last three months, and, apparently, depended upon diffuse bronchial catarrh. He was a member of a healthy family.

When examined on admission, his temperature was 104 deg. Fahr.; pulse 128; respirations 48 to the minute. There was dulness at the right base behind up to the angle of the scapula, and in front the dulness reached to the lower border of the fourth rib. The whole of the right chest was obviously distended, and its base measured half an inch more than the left; there was also an entire absence of tactile vocal fremitus corresponding exactly to the area of dulness described; the heart was not displaced, nor was the liver depressed. On auscultation, vocal resonance was absent over the lower part of the right lung; there was no tubular breathing, but faint crepitant rales were distinctly heard on deep inspiration; these appeared to be superficial in their origin. Over the upper part of the right lung there were abundant

most bronchitic *râles*, so also over the whole of the left lung. As the case went on, the temperature did not fall as it usually does in an ordinary pneumonia, but kept up into the third week of illness at the average of 102 deg. Fahr.

Throughout the illness, the patient was much prostrated; there has been no orthopnea, but hectic flushing has often been observed. The area of dullness over the right lung gradually extended, so that diminished resonance was observed over the whole of the front of the right chest, as also behind. At one time, the tactile vocal fremitus returned in some degree, and there was some resonance on percussion, while the crepitant *râles* were heard larger and looser, as if the air-passages were again opening up; vocal resonance, however, was still absent, and still there were no tubular breath-sounds at the base. There was no albuminuria.

There was some hesitation in arriving at first at a positive diagnosis in this case; it resembled in many respects a case of croupous pneumonia with plugging of the air-tubes, occurring in a lung previously the seat of scattered catarrhal pneumonia. The absence of any indication of displacement of the heart or of the liver, the subcrepitant *râles* heard apparently superficially over the right chest, and the return at one time of the vocal fremitus, seemed to indicate the presence of pneumonia rather than of pleuritic effusion; and the maintenance of the pyrexia also favoured the view of the existence of pneumonia to some extent of a catarrhal form.

On April 5th, the dullness over the right front had become almost absolute; the edge of the liver was felt depressed two or three finger-breadths below the margin of the ribs. There was complete absence of tactile fremitus over the lower lobe, yet, on deep inspiration, faint subcrepitant *râles* could still be heard all over the area of dullness. It was determined to make an exploratory puncture with a hypodermic syringe; serous fluid was withdrawn, and then, with the aspirator, forty-six ounces of clear straw-coloured fluid were removed. Immediately after the introduction of the needle (low down in the axilla), and before many ounces of fluid had been withdrawn, the point of the needle was felt distinctly to grate against the surface of the lung, and it had to be withdrawn partially and inclined obliquely in order to continue the aspiration.

REMARKS.—This appeared to be a case in which an acute attack of pleuropneumonia supervened on chronic bronchitis, probably complicated with patches of catarrhal pneumonia. Though from the first there was absence of vocal fremitus, and tubular breath-sounds over the area of dullness, while there was some bulging of the chest-wall, yet the occurrence of superficial subcrepitant *râles* on deep inspiration, and the partial return of vocal fremitus, together with certain of the general symptoms, gave rise for a time to the suspicion that the whole of the lower lobe of the lung had become distended with both croupous as well as catarrhal exudations; that the air-tubes were more or less blocked, which prevented transmission of any vocal thrill to the chest-wall, and accounted for the absence of tubular breath-sound. It would seem, however, to have been a case where the lung, more or less condensed by exudation and somewhat incompressible, was surrounded at its base by a not very deep layer of pleuritic fluid, so that on deep inspirations the slight movement of air in the superficial air-cells could be heard on listening over this area of dullness. It afforded a good example of the value of the hypodermic syringe for making exploratory punctures in such doubtful cases.

*A Case of Probable Pulmonary Stenosis: Unusual Seat of Cardiac Murmur.*—A girl, aged 19, came under observation complaining of pain in her left chest and shortness of breath, with occasional faintness, but no cough. These symptoms commenced a year previously, when she was laid up for a few days with what was termed "inflammation of the chest". As a child, she never could run without getting out of breath; but there never appears to have been any cyanosis. All the members of the family appear to be healthy, and there is no history of rheumatism in the patient or in her family. The girl is well nourished, and all her organs, except the heart, appear healthy.

The following were the physical signs of the condition of the heart. At the second left intercostal space, near the sternal end, *i.e.*, over the region of the pulmonary artery, a distinct vibratile thrill was felt; at the same spot was heard, with maximum intensity, a loud, prolonged, harsh, almost rasping *bruit*. This was the only *bruit* detected; it was conducted equally well in all directions, being still audible, but diminished in intensity at the apex and in the axilla. Outside the apex-beat in the axilla, the normal first and second sounds could be distinctly heard, indicating that the murmur was not of neutral origin. In time, the murmur occupied nearly the whole of the cardiac revolution, including the entire diastolic period. The pulmonary second sound was abolished, and was replaced completely by the murmur.

At the second right cartilage, *i.e.*, over the aortic area, the murmur was still heard, but with less intensity; the aortic click was distinct, though feeble. The murmur was also heard over the large vessels at the root of the neck on the right side, which prevented the absolute exclusion of all possibility of disease of the aortic valves. The area of precordial dullness was normal, or slightly increased in its vertical dimension. There was no very decided evidence of hypertrophy of either the right or the left side of the heart; the force of the impulse was not increased, but the apex-beat was somewhat displaced to the left. The radial pulse was jerky, rather small in volume, regular, 66 to the minute. The pulse in the carotid was locomotor, and suggested that the period of dilatation was prolonged. There was no venous dilatation or other sign of tricuspid disease.

REMARKS.—Dr. Yeo pointed out that this was an exceedingly rare form of cardiac disease. It was certainly not a case of auricular impulse in the second left interspace due to mitral stenosis or regurgitation, for, on listening a little outside the apex-beat in the axilla, quite normal cardiac sounds, systolic and diastolic, could be distinguished apart from the loud almost continuous murmur heard in the distance. Indeed, on listening carefully over the apex, one might fancy one was listening over two hearts, for to the right of the apex the normal cardiac sounds were entirely replaced by the loud, harsh, and prolonged murmur; while to the left of the apex the natural cardiac sounds could be distinctly heard. Absence of pulmonary second sound in the second left interspace, and its replacement by the murmur, also pointed strongly to the pulmonary orifice as the seat of the disease. Had the patient been a male, the strong tactile thrill and impulse in this unusual situation would certainly have aroused the suspicion of aneurism. Dr. Yeo leaned to the belief that this was a case of malformation of the pulmonary valves, not unlike a case previously under his care, in which the segments of this valve were so united as to form a narrow funnel-shaped orifice to the artery.

*Case of Cardiac Disease with high fluctuating Temperature.*—A male, forty-four years of age, was admitted on February 16th, complaining that he had been becoming thin and weak for the last twelve months, and that for the last three months he had had a cough. Latterly, he had noticed considerable swelling of the abdomen, with pain in that region. He had rheumatic fever when sixteen years of age, and had suffered constantly from rheumatism. On examination, a loud systolic *bruit* was heard both at base and apex of heart; loudest at apex. The liver-dullness was greatly increased, and extended from the upper margin of the sixth rib down to the level of the umbilicus. The spleen was also greatly enlarged. The urine was scanty and high coloured, free from albumen. The lung-sounds were normal. The tongue was clean. The gums were red, with a tendency to bleed; and occasionally there was a little blood-stained expectoration. The terminal digital phalanges of both hands were slightly bulbous, and of a curious bright rose colour, contrasting much with the pallor of the adjacent skin. The distal phalanges of the toes presented a similar appearance in a slighter degree. Pulse 90. His appetite was fairly good. The point of chief interest in this case was the range of temperature observed throughout. On the 18th, two days after admission, the morning temperature was 97 deg.; evening temperature 100.2 deg. On the 19th, the morning temperature was 98.8 deg.; the evening temperature 104 deg. Then, for two days and a half, it varied between 98.4 and 100 deg., and on the evening of the 22nd again rose to 103 deg., and for the next seven days oscillated between 98.6 and 103.4 deg.; the highest temperatures appearing to occur with something like regularity on alternate evenings—*e.g.*, evening temperature, on 21st, 100.2 deg., and on 22nd, 103 deg.; on 23rd, 100.6 deg., on 24th, 102.2 deg.; on 25th, 100.2 deg., on 26th, 103.2; on 27th, 100 deg., on 28th, 102.4 deg. But on March 1st, the temperature rose again in the evening to 103.4 deg., and the next day he was ordered three grains of quinine every four hours. The temperature then fell steadily about six degrees, and for three days and a half remained below 99 deg.; but, on the evening of the 4th, it again rose to 103.4 deg.; the next day kept below 100 deg., and the following evening rose to 103.6 deg.; the next morning fell to 97.8 deg., and then rose gradually for four evenings till, on the 10th, it was again 103 deg.; the quinine was increased to six grains every four hours, and then for four days the temperature only rose once above 100 deg. But on the 15th the temperature suddenly rose from 98.4 deg. to 104.6 deg.; eight grains of quinine every four hours were now given, and in less than twelve hours the temperature fell eight degrees and a half, and remained subnormal for two days. Then it again rose, in spite of the large doses of quinine, to 101.4 deg., and ranged for three days between 100 deg. and 103.6 deg. Salicylate of soda was given instead of the quinine, ten grains every six hours; at first, the temperature fell from 102.6 deg. to 97 deg. in twelve hours; after this, it gradually rose till March 26th, when

the patient had quite an acute febrile paroxysm. It began about 11 A.M., with slight shivering and feeling of cold; temperature 102.6 deg.; pulse 150; heart's impulse very strong; dyspnoea and a sense of dragging opposite the first piece of sternum; no tenderness over spleen; face flushed and dusky; surface warm. The temperature continued to rise till, at one o'clock, it reached 105 deg., and remained so for two hours; at 3 P.M., it began to fall; at 5, it was 102.6 deg., and he was perspiring (he had begun to take quinine six grains, infusion of digitalis sixty minims, every four hours); at 9 P.M., the temperature was 101.2 deg.; it rose again at midnight to 103.6 deg.; this was followed by a temperature-depression to 101 deg., then it rose to 104.2 deg. The dyspnoea was gradually increasing in severity; moist rales were heard at both bases; there was slight hæmoptysis, and a small quantity of blood in a motion which he passed, and shortly afterwards he died, March 28th. On *post mortem* examination, it was found that both aortic and mitral valves were the seat of old deformative changes. The aortic valves were thickened, and contained small calcareous masses; they were slightly incompetent, allowing of very small regurgitant stream, and the spot on the surface of the ventricle, against which this regurgitant stream must have impinged about an inch below the sigmoid valves, was the seat of a patch of endocarditis, from which long rough vegetations projected; and as these jutted out into the efferent current of blood, no condition could have been more favourable for the continuous production of fine emboli. The chordæ tendineæ of the aortic curtain of the mitral valve were ruptured, the free extremities being covered with black clot. The margins of the mitral flaps presented on their auricular surface a fine granular or rather eroded appearance; and this, together with the rupture of the chordæ tendineæ, suggested recent ulcerative inflammation. The lungs were oedematous, and the seat of hypostatic congestions; there was a small amount of effusion in both pleural cavities. The liver weighed 104 oz., and reached nearly to the umbilicus; it contained no evidences of coarse embolic infarction. The spleen weighed 43 oz., was of firm consistence, and, with the exception of one or two minute black spots close to the surface, presented also no signs of embolism. Small hæmorrhagic patches were found on the mucous membrane of the small intestine. The brain was slightly oedematous. There were no other noteworthy changes.

It was expected during life that *post mortem* examination would probably disclose coarse embolic changes both in the spleen and the liver, and thus account for the high fluctuating temperature. This, however, was not the case; and if the high temperatures observed were to be attributed to embolic process, they must have been capillary, and led to no appreciably naked eye changes. It is also possible that the physical conditions may have been dependent, to some extent, upon slow ulcerative endocarditis. There was no reason to suppose that the patient was affected with malarious fever. It was remarkable that the tongue remained almost constantly clean and moist, and the appetite fairly good.

#### JERVIS STREET HOSPITAL, DUBLIN.

EXTENSIVE COMPOUND COMMINUTED FRACTURE OF THE SPHENOID,  
WITH RUPTURE OF THE INTERNAL MAXILLARY ARTERY, AND  
SUBSEQUENT NECROSIS.

(Under the care of Dr. E. W. COLLINS.)

IN November last, a fine healthy boy, fourteen years of age, was struck in the left temple by a moulting cutter, propelled with considerable force from some machinery eighteen feet distant, which he was minding in a saw-mill. He was taken up senseless, and bleeding so profusely from the wound, that he quickly lost a large amount of blood. He was carried to the hospital in a state of syncope, due to the hæmorrhage and to concussion of the brain. A large lacerated wound in the left temporal fossa commenced immediately above the centre of the zygoma, and passed directly upwards for several inches. From a superficial examination, it was evident that the depth of the wound was considerable. Owing to the collapse, the hæmorrhage had ceased. The wound was interfered with as little as possible, and any detailed examination as regarded its depth avoided, in order not to disturb such natural hæmostatic processes as might already have taken place. Such superficial branches of the temporal artery as spouted when the wound was exposed were ligatured. The wound itself was cleansed, and its edges were brought together with sutures. Firm pressure was maintained over the wound by a large compress and knotted capeline bandage.

At his visit on the following morning, Dr. Collins learned that severe reactionary hæmorrhage had taken place at 5 A.M., which the resident pupil had great difficulty in arresting by continued pressure

over the wound. He had the boy then conveyed to the operating theatre, in order to thoroughly examine the wound and adopt such measures as might be necessary to prevent further recurrence of hæmorrhage. That the bleeding was arterial and from a vessel of considerable size, he was convinced by the time of its occurrence, its profuseness, and the difficulty experienced in its temporary arrest. Ether having been administered and the compresses removed, masses of coagula were seen filling the wound, and bleeding immediately took place. Clearing away the coagula, Dr. Collins passed his forefinger downwards and backwards through the wound, between the zygomatic arch and the pterygoid ridge of the sphenoid, into the zygomatic fossa, where the internal maxillary artery lies. The zygoma was felt bared of periosteum to some extent, but not broken. In the upper wall of the zygomatic fossa, the top of the finger passed into a large fissure, where the base of the great wing of the sphenoid was so extensively fractured that the pulsations of the brain were perceptible. No loose pieces of bone were felt. Meanwhile, arterial blood rushed so very profusely from the deepest part of the wound, either from the internal maxillary artery itself or from one of its larger branches—possibly the middle meningeal—that the boy, weakened by the two previous hæmorrhages, became alarmingly collapsed. By the aid of the hypodermic administration of ether, he rallied. Direct digital pressure within the wound somewhat controlled, but did not completely arrest, the flow. The depth from the surface of the zygomatic fossa in which the forefinger was buried; the narrow undilatable channel leading to it between the zygoma and sphenoid, which admitted little more than the finger; and the constant welling up of blood through the wound, rendered it impossible to ascertain with exactness the source of the bleeding. But one immediate hæmostatic measure was applicable, direct compression within the wound. Ligation of the carotid artery was reserved as a *dernier resort* in case of the failure of compression. The entire wound was carefully plugged from the bottom with long strips of lint; this most effectually checked the hæmorrhage.

The gradual removal of the plugs was commenced on the fourth day; from this time they were thoroughly carbolised. On the ninth day, the last plug was floated out without recurrence of bleeding. At each dressing, when the wound was filled with water, the fluid rose and fell in unison with the pulsations of the brain. Steady and progressive improvement was maintained daily. No untoward intracranial or other complications arose, owing, no doubt, to the very free bleeding, aided by ice to the shaved head, bromide of potassium, and purgatives.

The wound rapidly healed by granulation to a certain point. The sinus, which continued to discharge in January, afforded evidence that necrosis of the fractured sphenoid had taken place. The boy was sent to his home for some time, to allow the gradual and complete separation of the dead bone before its removal was attempted. On his return at the end of six weeks, the probe immediately struck loosened dead bone. On the following morning, having opened up the wound in the temporal fossa, Dr. Collins removed many large detached sequestra of the sphenoid. Smaller pieces subsequently exfoliated, and were withdrawn from time to time; till, finally, the last piece was extracted about five months after the accident, and the wound completely healed. The boy has presented himself at the hospital on several occasions, and is apparently in the enjoyment of excellent health, both mental and bodily.

In his remarks upon the clinical features of interest in this case, Dr. Collins drew attention to the symptoms presented by a man, under his care some months previously in the same ward, who had sustained severe cerebral concussion, with, probably fracture of the petrous portion of the left temporal bone, the result of a fall on his head from a scaffold. Considerable collapse and loss of consciousness existed. Both pupils were equally dilated, though perfectly sensitive to light, and the pulse from the outset was remarkably slow (about 40) and weak—conditions which continued for some weeks after admission. A flow of blood from the left ear was soon replaced by a clear fluid, which ran away for twelve hours. Tenderness on pressure existed over the mastoid and auditory processes. A few days after admission, his urine was found albuminous to the extent of one-ninth. Convalescence was extremely slow, lasting over several months. Even when last seen, the man was very anæmic, weak, and unable for mental or bodily exertion, pain in the head being readily excited. The albumen had disappeared from his urine.

From the marked and prolonged slowness of the pulse, dilatation of the pupils, and temporary albuminuria, succeeded by such tedious and imperfect convalescence, Dr. Collins formed the idea that, in the last-mentioned case, besides a probable fracture of the base involving the pars petrosa, a certain amount of hæmorrhage into the cavity of the

arachnoid had also taken place, which gradually became encysted and partly absorbed. He referred to the researches of Mr. Prescott Hewett and other writers, in connection with the pathogenesis of such arachnoid cysts as the result of hæmorrhage.

## REVIEWS AND NOTICES.

ON THE TREATMENT OF WOUNDS. CLINICAL LECTURES. By SAMPSON GAMGEE, F.R.S.E., Surgeon to the Queen's Hospital, Birmingham, etc. London: J. and A. Churchill. 1878.

MR. GAMGEE has recently devoted a course of lectures to the important subject which has of late years been attracting much attention from all surgeons who have the advance of their calling really at heart, and which may almost be said to have divided the profession by the heated discussions to which it has at times given rise. So much has this been the case, that it has become difficult for any surgeon who has stepped from the ranks of conservative orthodoxy to avoid becoming a partisan of this system or of that, and it is universally allowed that one of the privileges of partisanship is to decry all other systems than your own. Mr. Gamgee takes his stand, not simply as a partisan, but as the champion of a system of surgical dressing, and, as such, he claims his just rights. The main features of his system are the entire absence of moisture in the dressings, the maintenance of a moderately firm and uniform pressure over the wounded parts, and the insurance of absolute immobility and rest. The principal dressings advocated by Mr. Gamgee are cotton-wool, carded oakum, and styptic colloid; and these may be used either singly or in combination; and, to insure rest, millboard splints are in many cases superadded. The greatest care and nicety are employed in applying the dressings, and by these means Mr. Gamgee has been enabled to treat, with remarkable success, many cases of the most severe forms of surgical injuries. Mr. Gamgee does not give us the statistics gathered from his practice; but, from the data which his lectures supply, we may justly infer that his results have been considerably better than those which are usually met with in hospital practice.

He is not, however, content with bringing forward the most powerful argument in favour of his own system, viz., that it has enabled him to achieve results which have generally been looked upon as almost beyond the reach of surgical skill, but he endeavours to bring its merits into still greater prominence by annihilating the claims of other systems. A few, almost contemptuous, sentences suffice to dispose of plain old-fashioned water-dressing; but a far more imposing rival is found in the antiseptic system of Professor Lister; and it is the vigorous attack which he directs against this method of dressing which constitutes the *pièce de résistance* of Mr. Gamgee's book. We cannot but regret, however, that Mr. Gamgee should in this instance have broken the rule which he laid down for himself, to describe the various methods by which wounds may be successfully treated without entering upon controversial matter; for his careful description of the procedure adopted by Professor Lister, with the results of which Mr. Gamgee expressed himself highly pleased, is to some extent marred by the spirit of antagonism which he displays towards the whole system. Of these results, he says: "Collectively and separately considered, these results are admirable." Such being the case, why attack the method of dressing which produced them? The truth of the germ theory is not yet completely decided, one way or the other, to the satisfaction of the whole scientific world, and it certainly cannot be decided on *a priori* grounds. Still less can we expect to come to any *a priori* conclusion as to its applicability to practical surgery. The only way by which the matter can be settled will be by the comparison of statistics of the various methods of dressing, drawn up with great accuracy and on a sufficiently large scale to reduce the chances of fallacy to a minimum. These statistics have not been published; and we think, therefore, that it would have been better if a surgeon of acknowledged scientific reputation like Mr. Gamgee had waited, before attacking the system, until he had more data at his disposal. That these data may be obtained, it is absolutely essential that men, possessed of the patience and ardour of Professor Lister, should look steadily forward, year after year, accumulating results and perfecting their methods. Their earnest belief in the truth of the hypothesis which guides them, far from being an embarrassment in their work, is in reality essential to its proper performance; and we, therefore, differ altogether from Mr. Gamgee when he insinuates that the germ-theory is standing in the way of advance in surgical dressing. We cannot accept the argument, that the process of dressing is too elaborate to be used at the pit's mouth or on the battle-field. If it be ultimately found that a certain number of lives or limbs are saved by the antiseptic dressing, which would have been lost had other methods been adopted, this dressing should be used whenever practicable.

When we cannot have the best, we must be content with the best possible; and there is no worse fallacy than to suppose that, because a method cannot be universally adopted, no attempt should be made to adopt it at all.

It is curious to find that, whilst he has no mercy for the antiseptic theory, Mr. Gamgee in practice falls back upon it to some extent, for the three principal dressings which he advocates, viz., oakum, cotton-wool, and styptic colloid, are all used on account of their antiputrescent qualities. Of oakum, he says, "its antiputrescent qualities make it specially valuable when wounds are discharging"; of styptic colloid, he says, it is "also valuable for its antiputrescent properties"; whilst he quotes with evident approval M. Guérin's communication to the Académie de Médecine, in which the following passage occurs. "Cotton-wool, while preventing putrid fermentation, does not offer any obstacle to the penetration of air. . . . It only bars the passage to the parasites and other germs of fermentation contained in atmospheric air."

We have no wish, neither do we feel it possible at present, to pass any judgment on the antiseptic question; but we feel assured that nothing will be gained by attacks upon it based upon grounds which are entirely *a priori*. If the result were bad, there would be some excuse for attacking the method; but, so long as the results are acknowledged to be excellent—and, indeed, by many eminent surgeons of all countries believed to be incomparable—the method may very well be left alone until an inquiry can be made, with ample data, and in a truly scientific manner.

Apart from this matter, however, we have nothing but praise for Mr. Gamgee's work. He is clear in his descriptions of both his own method of dressing and of those of other surgeons, and a considerable number of cases are detailed in illustration. In the closure of arteries, Mr. Gamgee prefers torsion wherever this is practicable. He strongly advocates non-intervention in depressed fractures of the skull even where the fracture is compound, so long as there are no brain-symptoms. Throughout his work he appears as a champion of conservative surgery in its highest degree of development; and his book is, therefore, well calculated to advance the practice of the great art of which he is an able teacher.

THE ELEMENTS OF THERAPEUTICS: A CLINICAL GUIDE TO THE ACTION OF MEDICINES. By DR. C. BINZ, Professor of Pharmacology in the University of Bonn. Translated from the Fifth German Edition, and Edited, with Additions in conformity with the British and American Pharmacopœias, by EDWARD L. SPARKS, M.A., M.B. Oxon. London: J. and A. Churchill. 1877.

It is but rarely that a foreign work on therapeutics is translated into English; and, although Professor BINZ is a high authority, and Dr. SPARKS a very excellent translator, we fail to see any advantage possessed by these *Elements* over our own approved manuals; rather the reverse. Those who make a special study of therapeutics will find in it an useful summary, but those that expect a practical clinical guide may be disappointed.

The classification is simple, if not scientific, and is in part physiological, in part chemical. The twelve chapters deal briefly with twelve classes: 1-2. Nerve depressoria, excitantia; 3. Ethero-oleosa; 4. Emollientia; 5. Adstringentia, amara, alkalina; 6. Plastica; 7. Antidyscratica et antiseptica; 8. Antiseptica; 9. Antipyretica; 10. Evacuanta; 11. Caustica; 12. Mechanica.

The depressants are made to include opium, belladonna, physostigma, and aconite, chloroform and iodoform, ether and amyl-nitrite, the alkaline bromides, and oxide of zinc. By John Harley and others, belladonna is reckoned a cardiac stimulant; and Professor Binz records that it increases the pulse-rate; sometimes, but rarely, it seems to depress nervous subjects; yet it scarcely finds a consonant place in classification between opium and aconite. It cannot be that the ultimate poisonous effect is taken as a basis for its position; were it so, all poisons would come in the same category; for death by poison comes always with depression at the last. And again, digitalis, which in its full action is a typical depressant, comes in the second class—of excitants—with caffeine and ergot, tobacco and strychnia, ammonia and alcohol. Such conjunctions and disjunctions are rather novel than consistent.

Treating of ethereal oils, their antiseptic power, their lessening of reflex excitability, and their increasing the colourless blood-corpuscles, are recorded; but a large part of the section goes in simple enumeration of drugs and preparations—e.g., a page and a half to syrups and tinctures of orange, lemon, and ginger. It is true, that American preparations are given for comparison, but we scarcely appreciate the advantage that Dr. Sparks seems to expect from this. He hopes that the comparison may lead to simplifying both *Pharmacopœias*—a good

hope, doubtless; but materials already exist for use when the time is ripe, and the volume is not large enough to spare room for so much pharmacy. At the same time, we may allow some use in the comparison for those physicians who see many American patients on their travels. The retention by Dr. Sparks of the metric system is also, in one sense, a move in the right direction, but we think its adaptation to prescriptions really the last to be made; for us to use it for this purpose, before it is sufficiently vulgarised, would only lead to mistakes.

Referring to individual drugs, we find special attention given to their physiological action (only when important), brief notices of experimental research, and ingenious theories in explanation; but the statements are not very well arranged, nor are they easy to follow or grasp, so that one requires to be already fairly acquainted with recent work, in order to appreciate and digest them; and in the therapeutical part, to which in a "clinical guide" we naturally turn, we find little, if any, guidance or detail. The speciality of the work is rather that its endeavours to reason out the bearings of ascertained physiological fact, than to be guided by observations of disease. This is high scientific ground. In the statements themselves, there is no waste of words; they imply, we need scarcely say, intimate acquaintance with modern as well as original researches, and will well repay thorough digestion by an earnest student. It would be impossible, however, to practise from the book alone; it must be looked on rather as a summary and a text. Names of original writers are often given, but no references, which we much regret. About the confession of ignorance on certain points there is no scruple. Thus, "our clinical knowledge of hyoscyanus is thoroughly imperfect"; "we have very little scientific knowledge of pulsatilla" (*pace* Baron Störck); "nothing definite is known about the therapeutical use of aconite" (page 22) etc.

The first chapter, on opium, will illustrate most of our remarks. Morphia is taken as its representative, the therapeutical points of difference between it and the crude drug being disregarded. Small doses excite for a time; large ones quickly stupefy and paralyse, especially in highly organised nervous natures; the drug diminishes also the activity of respiratory centres in the medulla and the functions of cord generally, not of striped muscular tissue. Small doses stimulate the vaso-motor system, contracting the arteries; large ones paralyse, and depress temperature. In narcotised animals, septic injections produce no fever. Morphia diminishes intestinal sensibility, not the secretions; it diminishes carbonic acid, not urea; large doses paralyse the dilating power of the sphincters. The cells of the cerebral cortex have decided affinity for the drug, and are paralysed by it. Natural sleep is regarded as the result of fatigue of these cells, produced by accumulated products of tissue-change, and this result is imitated by morphia. It produces also anemia of brain; but this cannot be a main condition of sleep, because alcohol and chloral produce a sleep in which the vessels are not contracted.

As a remedy, morphia is used to diminish central and peripheral nervous excitement in many conditions, as in pneumonia, bronchitis, intestinal catarrh, typhoid fever, salivation, etc.; a mere enumeration, without any qualifying remarks. Its cautious use as an antidote to belladonna is recommended. The maximum dose of pure opium is set as fifteen *centigrammes* (two grains and a quarter); and we learn that in Germany the physician is required to place a note of admiration (!) on his prescription ordering this.

Then come three and a half pages enumerating the preparations of the drug, and a page as to its hypodermic use, one-thirteenth of a grain being indicated as the first dose. Cannabis Indica follows in the same section, occupying only a few lines. We learn only that it is said to induce sleep without unpleasant effects; nothing as to its value in dysmenorrhœa, menorrhagia, or neuralgia.

In regard to other drugs, nitrite-amyl, chloral, caffeine, ergot, mercury, certain sections may be more detailed; and we must add that all good new remedies receive at least a mention, and that Dr. Sparks has himself added to the text many useful paragraphs. But it remains that the treatise is essentially one of "elements"; and, whilst it has a value as a text and a summary, and a special value as representing the teaching of a distinguished professor, it is not likely to supplant the more practical English and American text-books already in use.

#### REPORTS ON VENEREAL DISEASES AMONG EUROPEAN TROOPS IN INDIA.

THE reports just published of the Lock hospitals—nine military and four civil—of the Madras Presidency, give full details for the year 1876 of the number and character of venereal diseases affecting the European soldiers, and the women registered under the Contagious Diseases Act in that presidency. They are chiefly interesting as affording data whereby to judge of the working of the Act in diminishing venereal

diseases. Most, if not all, the reports assert the benefits of the Act; but they all also agree in lamenting its inefficacy to meet the entire evil. In general terms, it may be admitted as a manifest fact that the destruction of the sources of a contagious disease must *pro tanto* diminish the spread of the contagion. But, in dealing with this particular contagion, there exists, as we find, an insuperable obstacle to its entire repression. Parent Duchâtelet forcibly felt this, and acknowledged that the root of the evil, and the main production of it, would never be reached unless clandestine prostitution could be controlled. This standing difficulty the medical authors of these reports acknowledge. In small towns, no doubt, the police can, in a large degree, lay hands effectively on the female sources of the disease; but, in large cities everywhere, and in country districts of India, this seems impossible. Prostitutes in India are not regarded as social outcasts. Prostitution, we are told, is there a recognised trade, "a form of religious consecration". Besides this, venereal diseases are very common in domestic life in the rural districts of India as well as in the towns, and "are not regarded with abhorrence, as in England". The worst "cases of syphilis in females which are admitted to hospitals come from country districts, and occur in the persons of married women or of widows who are not prostitutes". Under these conditions, it is no wonder that medical officers find their efforts largely neutralised. Clandestine prostitution is very extensive, and escapes control. Another obstacle arises in the very working of the Act. Its rigorous enforcement tends to produce the very evil it would cure. The result, we read, of an effective registration of women and of a detective agency is this: "A gradual diminution in the number of registered prostitutes; an abandonment of the station by them; an increase of clandestine prostitution; a diminution in the amount and severity of syphilis among the non-registered." Under these circumstances, we need not be surprised if the statistics give us no striking evidence of the benefit of the Contagious Diseases Act. Clandestine prostitution is widespread, and the worst form of disease exists amongst the non-registered. Indeed, a comparative reading of the reports of the medical officers shows that much caution is required in judging of the actual effects of the Act in the diminution of venereal diseases. It is generally admitted that these diseases in India, as elsewhere, are of a far less severe character now than they were fifty years ago, and far more amenable to treatment. This fact may be in part attributable to the elimination of what Mr. Syme used to call the mercurial disease in syphilis, in consequence of its treatment without the mercurial poisoning of other days. Then, again, conclusions from the statistics of one district, or from the comparison of any two years, are full of fallacy. Different districts give great differences with regard to the ratios to strength of admission to hospital of European soldiers.

The following, for example, are the numbers—ratios to strength per thousand—of European soldiers admitted to hospitals for venereal diseases during 1876 in the nine different districts of the Madras Presidency:—320, 280, 279, 210, 126, 166, 125, 98, 94. In all these districts, the Contagious Diseases Act is in operation. Taking the total number of cases during the last seven years which have occurred in these districts, the general average seems to be much the same. This may be inferred from the following table, which gives "the ratio per cent. of admission from venereal disease to strength".

1870	..	..	15.41	1874	..	..	18.59
1871	..	..	17.37	1875	..	..	19.32
1872	..	..	16.42	1876	..	..	17.92
1873	..	..	14.68				

These percentages are calculated on the total number of European soldiers, varying from 8,900 to 10,000, during the years given. In the report, we read, as a comment on these figures, that "venereal affections generally seem to have their times of increase; and that there are periods of maxima and minima every fourth year". In two of the stations where there are no Lock hospitals, and where the number of troops is 134 and 150, we find that, in the first, the ratio of admissions in 1864 per 1,000 was 44.7, and in the latter 38.6. These figures show plainly enough what caution is required in judging statistically as to the effect of the Contagious Diseases Act. The health officer of Madras, in his report, says: "It is constantly being asked, Has the Contagious Diseases Act done any good?" And he answers the question by what he seems to consider an unanswerable reply: viz., "that out of 10,827 European troops and 1,400 married women, having 2,900 children born to them and now living, not one of these children has been a subject of syphilis. This can scarcely be believed in a country of so much venereal disease. . . . The absence of all diseases amongst the children speaks well either for the freedom from syphilitic disease in the Madras Presidency or the morality of the married soldiers and their wives." Now, this asserted freedom from venereal diseases may be inferred from the fact that, of 10,827 soldiers, 1,852 were, in

1876, admitted into hospital for venereal diseases; and we have no information given us as to the condition of the children in former years to use as a comparison; and no account is taken of the great mildness of the character of venereal diseases at the present day in India. The fact, therefore, on which the health-officer relies is not of much value as it stands at present.

SYNOPSIS OF THE DISEASES OF THE LARYNX, LUNGS, AND HEART; comprising Dr. Edwards's Tables on the Examination of the Chest. By F. DE HAVIDLAND HALL, M.D., Assistant Physician to the Westminster Hospital. London: J. and A. Churchill. 1878.

THIS tabular form of showing the diseases of the larynx is quite novel, and may with advantage be extended still further in a new edition; to all students of laryngoscopy the tables are invaluable, and now that the use of the laryngoscope is no longer confined to a few specialists, but is in frequent employment with practitioners, their value will be enhanced. Our examining bodies, it is to be hoped, will be alive to the necessity of testing the knowledge of candidates in medicine upon these diseases of the larynx which, by the aid of the laryngoscope have been brought to light, and, but a few years ago, were almost unknown.

There is one very much neglected point in ordinary clinical teaching, upon which the late Dr. Hughes Bennett and Sir Wm. Ferguson insisted strongly in their clinical lectures; viz., making the students thoroughly acquainted with normal healthy structures, and the normal and healthy sounds of the various organs of the body. This is particularly necessary with the sounds of the chest before proceeding to learn diseased ones. The student could not do better than take Table II of Dr. HALL's synopsis, and examine as many healthy adults as he can come across, and so educate his ear. The arrangement of the chief diseases of the chest in parallel columns of symptoms, physical signs, and *post mortem* appearance, started by Dr. Edwards and extended by Dr. Hall, is most convenient; as, at a glance, the student can see what conditions are to be met with in any given stage; and, for the purposes of examination, this is invaluable, as it enables the student to place before the examiner in the best possible light the knowledge which he possesses, and the examiner is saved a great deal of trouble. Moreover, the plan inculcated in these tables of examining the chest in a methodical manner, making use of the methods of inspection, palpation, percussion, and auscultation, in the order given, facilitates a thorough examination of the chest, and prevents anything from being overlooked; and, after all, the definition of "genius being attention to trifles," is not far short of the truth. More mistakes are made in a physical examination of the chest from the disregard of a systematic plan, than from any other cause. The same may be said of medicine generally. A student cannot too early initiate himself into a habit of examining the body on a fixed and definite plan. Let the system be based upon what plan he may find easiest to himself, but let the order of his examination be always the same.

Not the least valuable part of the synopsis are the tables of differential diagnosis. These tables do not partake of the objectionable type of books brought out by "grinders"; they are skeletons which the students can habituate in his study of other treatises in medicine; and are invaluable aids, also, by the bedside, enabling him readily to compare signs met with in disease with those observed in health.

## NOTES ON BOOKS.

*Clinical Work* is the pleasant and rather novel title of a quarterly journal of Therapeutics and Public Health, edited by Dr. Andrew Davison, and published at Port Louis, Mauritius. The field of observation, if not large, includes many opportunities of interesting study; and the present number has some valuable notes on Malarial Fever, Dysentery, Tannin as a substitute for Quinine, and other subjects which are natural to the soil and climate.

The first number of *Brain, a Journal of Neurology*, is extremely good. It has a valuable series of original papers, all of which deserve reading. Those by Mr. Jonathan Hutchinson and Dr. Bevan Lewis are of the first order of merit; while M. Durel, in relating his recent valuable researches on Brain Traumatism, and Mr. G. H. Lewes on Motor Feelings and Muscular Sense, are distinctly original, although not altogether beyond the regions of actual doubt. The reviews are able, and the summaries well chosen. Altogether, this is the best neurological journal which has yet appeared, and, if it can be maintained—as we believe it can—at its present standard, deserves a permanent success. It will be simply indispensable to working students of the physiology and diseases of the nervous system.

## SELECTIONS FROM JOURNALS.

### SURGERY.

REFLEX PARALYSIS FROM PHIMOSIS AND ADHERENT PREPUCE.—Dr. W. H. Whitehead reports the following case in the *Cincinnati Medical News* for November 1877. John A., aged 7, was perfectly healthy up to the age of four, when he began to have convulsions, and continued to have them, without impairment of health, up to the age of six. Then he began to be clumsy, and finally became generally paralysed. When first seen by Dr. Whitehead, he could not move hand or foot, nor articulate a word; his expression was somewhat idiotic; his bowels were constipated, and he had been as long as ten days without a motion, even after taking several doses of castor-oil. On examining the abdomen, the penis was accidentally touched, when the organ became erect, and the boy instantaneously had a convulsion. His mother said that with every fit the penis became erect, and that he had as many as sixteen in twenty-four hours. On examination, he was found to have phimosis with adherent prepuce. He was circumcised, and the adherent membrane torn from the glands. Behind the corona was impacted sebaceous material. No medicines were given. On a next visit, two days later, the boy was sitting in a chair, with more intelligent countenance; his bowels had been moved regularly, and he had had only one convulsion. Five days afterwards, he could walk across the room, and had had no convulsions. In two weeks, he had very much improved.

TREATMENT OF FRACTURED CLAVICLE.—In the *Chicago Medical Journal*, Dr. H. Van Buren recommends the following method of treating fractured clavicle. A bandage three or four inches wide, of double thickness and sufficient length, is made. On one end a loop is made by returning the bandage upon itself and securing by stitches. The hand of the injured side is passed through the loop, and the loop is carried up to a point just below the axillary margin. This bandage is then passed directly across the back, and under the sound arm, and over the sound shoulder, and returned across the back and stitched to itself at the point where the loop is formed. The arm of the injured side is then flexed with the hand on the chest, pointing in the direction of the sound shoulder. Another bandage of double thickness, and of the same width, is pinned or stitched by one end to the lower margin of the first, in front of the sound shoulder. It is then passed diagonally downward, and across the chest, under the hand and forearm, which has been flexed upon the chest, and carried around the arm at the elbow, and back on the dorsal surface of the forearm and hand to the point from which it started, and this end is also pinned to the first bandage. The lower margins of this bandage are stitched together for a distance of three inches at the elbow, thus forming a trough for it to rest in. The same may be done at the upper end, in which the hand may rest. This sling serves the triple purpose of drawing the lower end of the arm forward and upward, and thus throwing the injured shoulder backward; it supports the forearm and hand in a comfortable and quiet position; and, last, it prevents the first bandage from cording under the sound arm, by its attachment to its lower margin.

### MIDWIFERY AND DISEASES OF WOMEN.

SURGICAL TREATMENT OF INTRA-UTERINE SUBMUCOUS FIBROIDS.—Dr. E. T. Easley (*Richmond and Louisville Medical Journal*, February) offers the following conclusions on this subject. 1. Cutting operations, for the removal of submucous intra-uterine fibroids, are not justifiable, unless it is evident that their presence endangers life. 2. Primary enucleation, when at all practicable, is slightly preferable to the secondary method. 3. In secondary enucleation, the surgeon need not be solicitous to remove the growth *en masse*; but when the process is once set up he may, with great certainty, rely upon its piecemeal disintegration. 4. In primary procedures, the treatment should be chiefly such as is best calculated to limit shock, and, afterwards, to nourish the patient and guard against pelvic inflammations. 5. In the secondary method, most authorities say the ergot of rye should be given to the extent of maintaining vigorous uterine action. Decomposing discharges and shreds of slough should be carefully removed, the patient's strength be sustained, and all constitutional measures to prevent septic infection strictly enforced. Locally, detergent fluids are to be freely used, and the utmost cleanliness observed. 6. The mortality has exceeded one-half, and it is not likely that it will ever be reduced to one-third, of all the subjects of operation.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 18TH, 1878.

CHOLERA IN THE RED SEA.

It is now possible to recount with some degree of completeness the general facts relating to the recent outbreak of cholera in Western Arabia and on the east coast of the Red Sea. It would be premature to discuss the very important bearing of these facts upon the vexed question of quarantine. Indeed, at a recent meeting of the Epidemiological Society, at which Mr. Netten Radcliffe communicated to the members the details of the outbreak as then known, he deprecated such discussion until later in the year, on the ground that, until the autumn had come and passed, we could not be quite sure that some parts of Egypt—Upper and Middle, if not Lower—had escaped infection. In this view of the question, the Society, as a whole, concurred; and we are not prepared to say that it was not the proper course for a scientific society to pursue. Mr. Radcliffe, moreover, showed how that, supposing, as is to be hoped will be the case, Egypt should escape any manifestation of cholera this year, the question as to the part which quarantine may have had in securing its exemption will be a very thorny one. For the recent extension of cholera into Western Arabia has not been the only recent extension of cholera beyond the boundaries of India. The disease spread to the frontier of Persia in 1876, and then appears to have died out. It is probable, therefore, he argued, that we have been witnessing in Western Arabia, as in the countries bordering Northern India, a partial extension of the disease, and not the beginning of a pandemic. The point here raised will prove a knotty one; and, for the present, we must leave it to the epidemiologists to knock their heads against it in their own good time.

Meanwhile, our Levantine friends are by no means disposed to postpone the discussion of the question referred to, and their conclusions therefrom. Quarantine was *their* bridge of escape from a great danger; and the danger having been avoided, as they think owing to this bridge, they are not in the least disposed to doubt the means by which they escaped. In truth, we learn that the facts of the recent extension of cholera in Western Arabia and on the Red Sea coast furnish, in the estimation of our Levantine brethren, a triumphant vindication of quarantine. At present, without committing ourselves to an opinion upon the subject, we may say (except for the important reservation as to other recent extensions of the disease made by Mr. Netten Radcliffe) the facts appear to be in favour of this view. At any rate, we cannot affect surprise that they should be regarded as proving it, so far as our present information stands. We do not propose to discuss the question at present; but it will be well that we should set forth the several facts bearing upon it as they have now become known to us.

We assume that the disease which has lately caused so much anxiety in the Red Sea was cholera, although doubts have been expressed on this subject by certain persons who are stated to have witnessed the malady at Jeddah. But it is quite incredible, having regard to the familiarity which the medico-sanitary agents of the Egyptian and Ottoman Governments have lately acquired with malignant cholera,

that a mistake could have been made in diagnosis by them. Indeed, unless the symptoms which characterised the progress of the malady in the recent outbreak, as detailed to us, were a pure invention, we know not what the disease could have been unless it were cholera. The doubts raised in this case seem to be of much the same character as those which have been raised as to the recent existence of plague in Mesopotamia. The doubters in the last-named instance, while denying the presence of plague, admit the existence of a plague-like malady new to medicine, and which they would designate "bubonic fever" or "plague-like malarial fever". In like manner, the doubters in the first-named instance, while refusing to admit the recent presence of cholera in Western Arabia, grant the existence of a "choleraic disease", and in effect, if not in words, would name it "choleraic fever". When we are reduced to the dilemma of choosing between the acceptance of a disease which is well known and a new disease which so closely simulates the other that it must be named from it, we shall be pretty safe in assuming that the known disease is in question.

The existence of cholera in Western Arabia, at Mecca, appears first to have become known to the Egyptian General Board of Health on the 1st of January of this year. Two days before this day, the first ship bringing pilgrims returning from Mecca brought up at the quarantine station at Tor, in the Gulf of Suez. The news of the appearance of cholera at Mecca was presently confirmed, and measures were taken by the Egyptian Board which practically amounted to an entire cutting off of all communication, whether by sea or land, with the infected locality until the outbreak of the disease came to an end. As the facts relating to the disease accumulated, it became known that cholera had first been recognised at Mecca almost immediately after the termination of the rites of last year's pilgrimage, and at a time when the pilgrims were dispersing rapidly. But there is little doubt that the disease showed itself earlier than the 23rd, and that a knowledge of its existence was either unknown to the Ottoman sanitary officials or suppressed by them. Of the source of the disease in Mecca nothing is as yet known; and, under the circumstances of its first announcement, it is to be feared that nothing will now be ascertained. Of the caravans of pilgrims leaving Mecca of which we have any knowledge, almost all carried the infection with them. In Mecca, the disease lasted until January 11th, and within that period killed, as is reported, seven hundred and eighty-five persons. The pilgrims returning to Jeddah carried the disease with them thither, and in that town it occasioned two hundred and seven deaths, the last occurring on February 27th. Pilgrims and troops travelling from Mecca to the towns on the coast south of Jeddah also carried cholera along with them, and the disease showed itself in Gofudah and Hodeida and some intermediate places. The northern caravans appear to have borne the infection more freely along with them than the southern. Thus the Syrian caravan, consisting of five thousand persons, lost one hundred and sixty-nine from cholera between Mecca and Medina; and the Bagdad caravan, consisting of two thousand five hundred persons, lost ten. The disease was introduced into Medina, and killed over one hundred people there. The Egyptian caravan, consisting of eight hundred and fifty persons, did not have a single case of cholera on its route homeward. The infection does not appear to have been propagated from Medina, and among the numerous pilgrims who proceeded thence to Yembo to embark for the sea-route no case of cholera was reported; but during the stay of these pilgrims at Yembo, twenty-nine fatal cases of diarrhoea occurred.

The great interest of this outbreak, so far as Europe is most immediately concerned, rests in the transmission of cholera on the sea-route from Jeddah and Yembo to Suez. About sixteen thousand pilgrims travelled homewards by this route, and underwent quarantine at Tor. Thirteen deaths were reported during the passage, of which *one* only was assigned to cholera, and five to diarrhoea; and, during the stay of

the pilgrims at Tor, the number of deaths from cholera was six, and of diarrhoea fifty-two. The pilgrims were detained at Tor until the remotest chance of cholera existing among them seemed to be excluded, when the quarantine was raised, and the pilgrims were despatched to their several destinations, those destined to other countries in the Mediterranean than Egypt being sent through the Suez Canal and quarantine. It is believed that no evasion of the quarantine at Tor occurred. Several native craft with pilgrims on board, and bound for the African coast, attempted evasion; but it is said that the measures adopted to arrest these craft at their several destinations before the pilgrims and crews landed were successful. The Egyptian Board of Health, in fact, believes that the stream of infection in course of flow from Jeddah and Vembo to Suez and Lower Egypt was effectually stopped at Tor, and that Egypt has thereby been saved from the introduction of the disease into her midst.

Has this stoppage been so effectual as that Board believes; and, if so, has Egypt thereby been saved from another epidemic of cholera? The answer to these questions is not wholly upon the surface. We shall postpone their consideration for the present; but meanwhile we would observe that the Epidemiological Society could not render a more useful service to the profession, than by subjecting them to detailed discussion when the time serves.

#### A SCOTCH CAUSE CÉLÈBRE.

SINCE the trial of Dr. Pritchard at Glasgow in 1865 for the murder of his wife and mother-in-law by aconite, no case has come before the Scotch Criminal Courts which has excited so much interest as that of M. Chantrelle before the High Court of Justiciary in Edinburgh. To find any case similar to this in the records of our English courts, we must go back to the trial of William Palmer, who was convicted in May 1856 of the murder of his friend Cook. Aconite, strychnia, and morphia were the poisons selected by the three criminals; and the mode of administration was carefully chosen in each case, with the intention of misleading the scientific witnesses and defeating chemical research.

The case of M. Chantrelle, which was the subject of a trial in Edinburgh during the last week, presented the same scientific difficulty as that of Palmer. Although recently administered, no trace of the poison by which death was said to have been caused could be detected in the dead body of the victim. Hence we find the counsel in the case of Chantrelle resting the main part of his defence on this fact, and adopting the language of the late Serjeant Shee in defending Palmer: "If he died of it, the poison must have been there; and, if there, it must have been found."

The prisoner Chantrelle was indicted for administering an opiate poison to his wife on the night of January 1st, 1878. There was no direct evidence of the administration; it could only be inferred from the medical and other circumstances surrounding the case. The evidence showed that the parties had lived unhappily; but there was nothing in the conduct of the prisoner at the time of this occurrence to lead to the belief that he would destroy his wife by poison. On December 31st, she was in perfect health, in good spirits, and occupied herself in household work. In the evening, she had some champagne with her husband, and went to bed as usual. On January 1st, she felt unwell, and went to bed early. At 9.45 P.M., she was seen by her servant lying as if in her usual health. After this, the prisoner went to his wife's bedroom. How long he stayed there, and when he returned to his own room, is a matter of conjecture. The servant heard a groaning at six in the morning, when she got up. She went to the deceased's room, and found her insensible, groaning, and lying on her left side; the clothes greatly disturbed. She found it impossible to rouse her or to make her speak. The bedroom-door was open, whereas it was

generally shut; while the gas was out, although it was usually kept burning. She called the prisoner, who tried to rouse the deceased, but without success. He sent the servant out of the room on some pretext; and, on her return, she found him coming from the window, which he had opened; and he then asked the witness whether she did not smell gas. In a minute or two, she perceived it, although she had not perceived it in the room at any time previously that night. In reference to this fact, which is of importance in relation to the allegation of gas-poisoning, it was subsequently found that the gas-pipe, which was behind the shutter of the window from which the prisoner was seen coming, had been quite recently broken; and, as the gas had been shut off at the meter, that which gave the smell was the residuary gas contained in the pipes.

Two medical gentlemen, who were called to see the deceased, at first suspected that it was a case of gas-poisoning. The facts above mentioned, however, were not consistent with this theory; and, in the judgment of these gentlemen, as well as of others who were subsequently consulted, the symptoms and appearances were not such as would be produced by gas.

The deceased was removed from her bedroom at half-past eight A.M.; she was taken to the Infirmary at two, and died at four o'clock P.M. The main question at the trial was, What was the cause of death—the breathing of gas, or a narcotic poison administered by the prisoner? The circumstances were adverse to the theory of gas-poisoning; and it was alleged, on the part of the prosecution, that this theory had been put forward by the prisoner to conceal the real cause; the prisoner having broken the gas-pipe in the bedroom, so that there might be an escape at the time his wife was discovered. Until he had had an opportunity of doing this, there was no smell of gas; but the deceased was at that time quite insensible. Besides, as the gas was shut off at the meter, the contents of the pipes only would have been discharged, had there been a spontaneous leakage during the night from any accidental cause. This would not have sufficed to produce gas-poisoning, especially as the door of deceased's room was found open.

Dr. Littlejohn, who examined the body, found it in all respects healthy. There was no organic disease. The appearances were consistent with narcotic poisoning; but, as the learned judge observed on this part of the evidence, the *post mortem* examination could throw no light on the question of opiate-poisoning. Opium left no marks of its action, and no traces of opium could be detected in the body by the two principal scientific witnesses, Drs. Littlejohn and MacLagan.

A remarkable feature of this case is that, although the viscera yielded no traces of opium or its principal constituents, morphia and meconic acid, yet the clothes worn by the deceased supplied the chemical evidence which was required.

It was proved that, on the sheet upon which the deceased lay during the night and down to the period of her death, as well as on her night-dress, there were yellowish stains and other stains of a darker colour. The constituents of opium (morphia and meconic acid) were found in these stains by Drs. MacLagan and Littlejohn, as well as by Professors Fraser and Crum Brown. The evidence given by these experienced experts on this fact is conclusive and satisfactory.\* It was suggested

\* In order to weaken this part of the case, Mr. Falconer King, city analyst, was called for the defence, and according to this witness, to quote the words of counsel, "the reactions they obtained were not conclusive proofs, were not proofs at all; they were scouted by Mr. Falconer King as proofs of the existence either of meconic acid or morphia". On turning to the report of Mr. King's evidence, we find that the tests for meconic acid and morphia were not properly applied by him. Corrective experiments were not performed by this gentleman on his first results; hence the apparent discrepancy between his statements and those of the four eminent experts called for the prosecution. The suggestion made by Mr. King, that a crystal of morphia would have furnished better evidence than that presented, will appear absurd to those who know that there is nothing characteristic about this crystal of morphia, and that it could not be pronounced to be morphia except by the application of the tests actually employed by the experts and objected to by Mr. King. It would, besides, be a novelty to obtain hexahedral prisms of morphia from such slight yellow stains caused by opium on linen as are here described. The Lord Advocate's cross-examination of this witness showed that he had omitted a number of precau-

that these stains had the properties of extract of opium. Some had been produced by vomiting, others by parts of the sheet coming into contact with the dress.

From these results, all the experts came to the conclusion that, at some time during the night of January 1st, the deceased had had administered to her (for suicide could not be suspected) a dose of extract of opium. It was proved that the prisoner was the only person about the deceased who had the opportunity of administering a narcotic; and, further, that he was in possession of numerous drugs, including opium, of which he had a fluid extract. It was also proved that he had procured a drachm of this substance in November 1877.

The evidence, scientific and general, therefore, showed that the prisoner had clearly the means and opportunity of administering poison; and the other accompaniment of guilt, motive, was not wanting. This hardly comes within the scope of medical criticism; but it may be observed that there was circumstantial evidence that husband and wife had lived unhappily. The prisoner had insured her life for £1,000 in an accidental death insurance company, and he was, therefore, interested in her death from any accident such as gas-poisoning. The prisoner had many drugs and poisons in his possession; he knew their properties, and had threatened to kill his wife with poison which, as he said, the Faculty of Edinburgh could not detect.

A very skilful and elaborate defence was made by Mr. Trayner, the counsel for the prisoner. Although he denied that death had taken place from opium, he suggested no reasonable cause for the coma and the other narcotic symptoms, or for the fatal results after about the average period. He could suggest no disease which would have destroyed life under the circumstances, and have left no trace of its existence in the body! Like a judicious advocate in a bad case, he contented himself with criticising the evidence of the medical witnesses for the prosecution, without substituting any theory of his own to account for death. The following extract from his clever address involves so serious a scientific error that we cannot do otherwise than expose it. He is represented as saying that "he believed this was perhaps the first criminal case in which the jury had been asked to hold a person guilty of poisoning, where nothing in the body killed had been found to show the cause of killing". This statement implies that no person has ever been convicted of poisoning unless a portion of the poison had been found in the body after death. The fallacy of this proposition was well exposed on the trial of W. Palmer in 1856. It is well known that the jury convicted that notorious criminal, although the cause of the killing was not found in the body of his victim.\*

In the annals of criminal poisoning, this case will take rank with those of Palmer and Pritchard. In it we find a clever well informed man coolly laying his plans to destroy his wife by narcotic poisoning, secretly giving it to her in a form to operate quickly, and in a quantity not to admit of any detection in the body; trying to make it appear as poisoning by the escape of gas. Yet his ingenuity failed him at all points. There was no necessity for his suggesting any cause of death, such as gas-poisoning, or for breaking the gas-pipe in the bedroom to give plausibility to his suggestion. These acts served only to raise suspicion, and, as a rule, every effort made by a criminal to avert suspicion adds to the force of the circumstantial evidence against him.

tions in using his tests, and that, had these been observed, his results would have substantially agreed with those obtained by the witnesses for the prosecution.

In his address to the Court after his conviction, the prisoner utterly repudiated the chemical defence set up for him in reference to the detection of morphia and meconic acid. He admitted that opium was in the stains, but that he did not put it there. He suggested that the stains had been rubbed in by some person.

\* In Alison's *Criminal Law of Scotland*, page 75, is recorded the case of a woman Humphreys, tried and convicted at Aberdeen in 1830 for murdering her husband, by pouring oil of vitriol down his throat. The man survived two days. Not a trace of the poison was discovered in his body, but some spots of vitriol were found on the night-dress of the woman! This was the only evidence; but it was accepted as satisfactory proof, and the woman was executed for the crime.

Using the language of one who has commented on this case: "His motives for the crime of which he has been found guilty; his ability to commit it; his various ineffectual attempts to hide it afterwards, all combined against him, and led to his conviction."

WE regret to announce the death of Dr. Jephson, who expired at his residence, at Leamington, on Tuesday last. We hope next week to publish a memoir of this well-known physician.

AN anonymous benefactor has founded a prize of 6,000 francs (£240), which will be awarded by the Academy of Sciences, Paris, in 1880, for the medical application of the researches of M. Pasteur.

M. LANNELONGUE has investigated the inflammation of the apophyses during the period of growth. These inflammations are often due to muscular fatigue.

MR. JOHN ERIC ERICHSEN, F.R.S., will preside at the annual festival, in aid of the funds of University College Hospital, to be held at Willis's Rooms, King Street, St. James's, on Tuesday next, at 6.30 P.M., when it is hoped that old students will liberally support him.

M. TILLAUX has performed coxo-femoral disarticulation with the thermo-cautery and the galvano-cautery, a proceeding which he recommends in cases where complete hæmostasis is necessary.

DR. FANO has put forward a new theory of visual accommodation. According to his view, the notion of variable distance of objects is due to the formation of more or less distinct images on the different regions of the retina.

AT a meeting of the Lancashire Branch, held last week in Liverpool, it was unanimously resolved to oppose any Bill for the amendment of the Medical Acts which did not include provision for the compulsory formation of conjoint examining boards, and for the direct representation of the profession in the General Medical Council.

M. ROGER-MARVAISE has again laid on the table of the Chamber of Deputies a restrictive proposition for regulating the practice of medicine in France by foreign physicians and surgeons, graduates of foreign universities.

A MEETING of the Metropolitan Counties Branch of the Association will be held at 11, Chandos Street, on Wednesday next, at 8 P.M., when papers on Vaccination will be read by Dr. E. C. Seaton and by Dr. John Greene of Birmingham. It is hoped also that a communication on the subject will be made by Mr. Ceely of Aylesbury. The well-known reputation of these gentlemen as authorities in matters relating to vaccination is a sufficient guarantee that their communications will be of great interest and value, and it is hoped that the members of the Branch will attend in large number on the occasion.

MR. JOHN BRIGHT has once more expressed himself publicly in favour of selling indulgences to propagate small-pox. He is of opinion that the payment of the first fine should serve to procure immunity from further prosecution; in other words, that every father should be at liberty to sacrifice the life of his children by omitting to protect them from the infection of small-pox, and to set up the foci of a dangerous and infectious disease, on payment of twenty shillings. A more pernicious and surprising doctrine was, perhaps, never before put forward by a statesman of position.

THE duties of medical officer of health are sometimes performed under difficulties of an almost insurmountable kind. Dr. Bristowe has endeavoured to "inspect" the gipsy encampments at Dulwich, which are described as being the source of intolerable nuisances; but, owing to the appearance of several ferocious dogs kept by the gipsies, he had to beat a retreat. The magistrate "felt powerless to act"; and Dr.

Bristowe, under the fear of being reduced to a similar state of powerlessness, very naturally refuses to act. The tax-gatherer ought to try to collect licence-money for these dogs, which appear to possess unusual privileges.

M. MAGNAN has been studying afresh the physiological relations of substances having a serial chemical relation. Examining the physiological relations of allylic alcohol, he has arrived at the following principal conclusions. Allylic alcohol slowly precipitates albumen, renders brown the defibrinated blood, to which oxygen cannot restore its colour: it kills the figurate ferments, and arrests the movements of inferior organisms; but it has no action on the soluble ferments, and does not paralyse the properties either of diastase or of ptyaline. It is less rubefacient than essence of mustard. It is a rather powerful poison, which kills dogs in forty minutes. In the series of monatomic alcohols,  $C_2H_{5.4} + 2O$ , the transpirability increases with the volatility, and the figure which expresses it is about the same as the index for carbon in the formula.

#### EARL RUSSELL.

WE are happy to learn that the improvement in the health of Earl Russell continues, especially as regards strength and consciousness: there is also less fever.

#### INSTITUTION CONTRACTS.

A NUMBER of wholesale grocers, who were found to have supplied Hanwell Asylum with "cocoa" consisting of 25 per cent. of added starch, 32 per cent. of sugar, and 3 per cent. of red earth, justified themselves on the ground that the contract price was only £2 per cwt., while it is well known that genuine cocoa sells at the rate of £7 per cwt.; and that it could not, therefore, have been in the minds of the committee that they were going to be supplied with genuine cocoa. This is, of course, not a valid defence; but it is undoubtedly the fact that the committees of many workhouses, hospitals, etc., are in the habit of giving out contracts for necessary articles of daily diet at prices which preclude the possibility of the old people, sick people, and children under their care being supplied with genuine and unadulterated food. It has been conclusively shown, by series of analyses published by Mr. Wanklyn for the Government, that the workhouse milk generally is skimmed and watered; and our own published investigations show the same state of things to prevail largely at hospitals. To this, and as partly explaining it, we may add that we are informed that vendors of pure milk on the largest scale, such as the Aylesbury Dairy Company, habitually decline to send in contracts for such institutions, as the prices offered are such that it is not possible that pure milk should be supplied. The kind of economy which encourages and accepts spurious, deteriorated, and impoverished articles of food for the carefully limited dietary of public institutions, in order to effect an apparent saving, is most honoured in the breach. Some improvement has been effected in many of the principal metropolitan hospitals since we have repeatedly called attention to the subject; but there is still much room for further improvement.

#### VACCINATION AND INFANT MORTALITY.

ON the strength of a spuriously arranged Parliamentary return, which owes its origin to the ingenuity of anti-vaccinationists, a mischievous assertion is being widely disseminated, that there has been a marked increase of infant mortality in England since the Vaccination Act of 1853 made infant vaccination compulsory. Unlike many other of the reckless assertions of this party, this assertion can be very easily disposed of by the simple statement of the fact, that English infant mortality has declined, and not increased, since vaccination became compulsory. The return in question does not afford any information relating to infant mortality from *all causes*, but only from a selected list of fifteen specified causes, the value of the supposed connection between which and vaccination may be inferred from these including diarrhoea, cholera, and diphtheria. It appears to be true that the mor-

ality from these selected diseases has increased; but the return carefully keeps in the background the more than compensating decline of mortality from the other causes. The unvarnished facts of English infant mortality from *all causes*, during the past thirty-one years, are as follows. During the seven years 1847-53, before vaccination became compulsory, the deaths of infants under one year of age were equal to 156 per 1,000 births registered; during the next fourteen years, when, in the words of the return, vaccination was obligatory, the rate of infant mortality declined to 153 per 1,000; and in the ten most recent years 1868-77, during which, in the words of the return, vaccination has been enforced, infant mortality further declined to 152 per 1,000. In the face of these facts, the assertion of a recent increase in the rate of infant mortality, and its attribution to vaccination, is being scattered broadcast among the poor and ignorant, in order to promote anti-vaccination opinions. Unfortunately, the return to which we have alluded is so ingeniously contrived that its figures have been very generally misunderstood; and the increased infant mortality, from the fifteen selected specified causes, has been mistaken for an increase in the rate of infant mortality from all causes. It is impossible to condemn too strongly the publication, in the form of Parliamentary returns, of such worthless and misleading statistics as those to which we have alluded. The cost of such a return must be considerable; but its power for mischief, as it appears, is still greater.

#### VIOLENT DEATHS.

THE deaths referred to different forms of violence during the first quarter of the present year were 4,086, and were fewer than in any quarter since the second of 1873, notwithstanding the increase of population; they were equal to an annual rate of 0.67 per 1,000 persons living, and to 2.9 per cent. of the deaths from all causes. In the agricultural counties of the South Midland and Eastern Divisions, the death-rate from violence did not exceed 0.43 and 0.46 per 1,000, whereas it was equal to 0.72 in the Northern, 0.74 in the Welsh, and 0.93 in the North-western Divisions, in each of which the greater part of the population is engaged either in mining or manufacturing industries. In the twenty large towns, the death-rate from violence averaged 0.82 per 1,000, and ranged from 0.25 and 0.46 in Portsmouth and Brighton, to 1.16 in Birmingham and 1.24 in Liverpool.

#### THE FRENCH POISONING CASE.

REFERRING to the recent trial of the chemist Danval for poisoning his wife (which has lasted a week, and has excited great public and scientific interest), our Paris correspondent writes:

"The accused, Danval, a pharmacien, was charged with having caused the death of his wife by slow poisoning with arsenic. They were only about eighteen months married, for the last twelve of which the victim was always more or less ailing. She was troubled with almost incessant diarrhoea, vomiting, a parched mouth, and a sense of burning in the throat. These symptoms were accompanied with steadily increasing debility and emaciation, of which she eventually died; but, as the medical men who were called in from time to time for advice could not discover any malady to account for the above symptoms, this, coupled with the brutal treatment of the husband, awakened the suspicions of the young woman's parents, caused the exhumation of the body thirteen days after burial, and led to the arraignment of their son-in-law. To bring home the charge against the prisoner was a most difficult matter, and only for the discovery of the presence of arsenic, infinitesimal though it was, the accusation would certainly have broken down, and yet it was this part of the evidence that was most contested. Dr. Bergeron, already known for his experience in matters of medical jurisprudence, assisted by Dr. Delens and M. Pélissier, a distinguished chemist, was engaged for the prosecution. These gentlemen detected arsenic in the stomach, liver, and intestines, but the quantity was so small (one milligramme, or 15-thousandths of a grain) that it was considered insufficient by the defence to cause death. Whereupon other experts were called in, among whom were, M. Bouis, formerly Professor of Toxicology at the Arts et Métiers; and Dr. Cornil, Agrégé of the Faculty of Medicine, and one of the most distinguished histologists of our time. These gentlemen declared that, owing to the absence of the lesions characteristic of poisoning by arsenic, death must have taken place by other cause or

causes. Here I should mention that Dr. Cornil merely gave his opinion on the written report that was presented to him, for he had nothing to do with the necropsy. Professor Gubler was then called in, and he declared that the characteristic lesions of arsenic-poisoning are not always present, as it depends on the mode and length of time of its administration. Dr. Gailard was incidentally called in, and he declared that not only that death in this case could not have been caused by arsenic-poisoning, but that the quantity found in the body might have been absorbed from the particles emanating from the curtains in the bedroom, which were dyed with aniline. When doctors disagree, who is to decide? or, as the French say in such cases, 'Hippocrate dit Oui, Galien dit Non.'

#### THE ARMY HOSPITAL CORPS.

ON the occasion of the review of the troops quartered at the Camp at Aldershot, on the 13th instant, by Her Majesty, the Queen saw march past the saluting-point, for the first time, a large body of the Army Hospital Corps. According to the description of one of the correspondents of the *Times*, "the rear of the column was brought up by the Army Hospital Corps, perhaps the most useful body of men on the ground. Their marching was most creditable, and their appearance neat and smart". The men to whom these laudatory remarks refer were not a small party brought together for the occasion, but equalled in strength a regiment of the line—about nine hundred strong—and were fully trained and equipped for taking the field. They were under the command of Deputy Surgeon-General W. A. Mackinnon, C.B., and the medical officers acting under him. Few probably realise the immense change in the status and position of the Army Medical Department, which is indicated by the mere fact of medical officers marching past and saluting with drawn swords on parade and in the presence of the Sovereign. It is little less than a revolution in the traditions of the medical service, and must have been the subject of much criticism among the various arms of the service who witnessed the occurrence for the first time in a review of British troops. We believe that there is solid ground for anticipating that the command with which the army surgeons have at last been invested over the men specially trained to execute their directions, will be found to conduce greatly to the benefit of the sick and wounded soldiers of the army, not only on occasions of active service in the field, but on all occasions. It must insure more strict attention to instructions, and will show the men that they are to look up to their immediate superiors for interest in their welfare, and not, as has hitherto been the case, to other officers who had no means of rightly judging regarding them or their conduct. At the same time, the medical officers will feel that they are no longer in the anomalous position of having men given to them for the purpose of assisting them in their duties without having any direct authority over them, or possessing any means of enforcing obedience to their professional directions. We congratulate the officers of the Army Medical Department on this important alteration in the regulations affecting their service, the results of which it will require some time to fully appreciate.

#### REVACCINATION IN THE FRENCH ARMY.

WE were recently led to make some exposure of the spurious and misleading anti-vaccination statistics, which are widely circulated. We did so because the occurrence of small-pox in the French and German armies during the war of 1870-71 had been advanced by the President of the "National Anti-compulsory Vaccination League" as a proof of the futility of revaccination in warding off the disease. Our observations were chiefly derived from the experience of the effects of revaccination in the Prussian army of late years, and they sufficiently showed the utter groundlessness of the statements which had been set forth regarding its inefficacy as a prophylactic measure so far as that army was concerned. We have since been put in possession of a few notes on the subject of revaccination in the French army by Dr. Vallin, who holds an influential position in the Val-de-Grâce at Paris. The information contained in them has some features of special interest, and is well worthy of record. Dr. Vallin mentions

that a ministerial decision was come to so far back as the year 1858, chiefly at the instigation of Michel Lévy, that all soldiers should be revaccinated at the time of their entrance into the French army. The measure, however, remained a dead letter, although attention was repeatedly called to the subject. This fact was attributable partly to want of energy on the part of superior officers in insisting upon its execution, and partly to difficulties in procuring vaccine matter in sufficient quantity. The surgeons of regiments contented themselves with vaccinating all those soldiers who did not bear evident traces of vaccinia or small-pox. As to the outbreak of small-pox in 1870-71, Dr. Vallin writes, it may be affirmed that, in one hundred thousand soldiers called by the necessities of the war, ninety thousand had not been revaccinated; while a certain number who, although placed on the military rolls, never joined their regiments, from various causes, had probably not even been vaccinated. Since 1871, stricter measures have been taken to cause every soldier to be revaccinated, and they have been particularly enforced during the last four or five years. All the regiments in a garrison now send their men at stated periods to the military hospital, where vaccine-bearing children have been previously assembled by the medical officers, an indemnity being paid to the mothers for their attendance, and from these children the men, without exception, are vaccinated or revaccinated, as the case may be. As an indication of the advantageous effects of this system, it is mentioned that whereas, when revaccination was tried in the regiments, not more than four or five in a hundred proved successful, now in the hospitals revaccination gives from 30 to 36 per cent. of successful results. Dr. Vallin has had special opportunities of observing the effect of revaccination when outbreaks of small-pox have occurred, as he has charge of the small-pox patients at the Val-de-Grâce, when there are any. Records are kept of every patient, and these show that very rarely indeed is there mention of the man actually attacked by small-pox having been successfully revaccinated during the preceding or antecedent year. More frequently, the statement occurs that the man has been "revaccinated without success". Lastly, in nearly half the cases of small-pox, there is the positive fact that the men had not been revaccinated, either because they happened to be absent from the regiment with the commanding officer's leave, or detached on some outpost, at the time of the general annual revaccination, or because they had been less than a year with the corps, and that the epoch of revaccination had not arrived at the time when they were attacked. When writing his letter, Dr. Vallin happened to have at hand the annual report for the year 1873; and, on referring to this, he found there were only 132 cases of small-pox in the whole French army of 391,000 men. This was an exceptionally fortunate year probably, but it is interesting to note that, of the 132 cases which did occur, 4.8 per cent. had neither been vaccinated nor had had small-pox, 9 per cent. had previously had small-pox, 77.2 per cent. had been vaccinated but not revaccinated, while 9 per cent. had been both vaccinated and revaccinated. The general effect of Dr. Vallin's observations in the French army has been to lead him to regard vaccination as the truest and most reliable prophylactic measure against the disease of small-pox.

#### VOLUNTARY LOCK HOSPITALS.

It has been repeatedly asserted by the opponents of the Contagious Diseases Acts, that, if these were repealed, voluntary efforts would be found amply sufficient to provide and maintain the necessary lock hospital accommodation. During the last debate in the House of Commons, on a motion for the repeal of the Acts (July 19th, 1876), Mr. Stansfeld is reported in the *Medical Enquirer* to have used the following words: "I believe that when this legislation is removed—and it will ultimately be removed—there will be an immense and favourable revulsion of public feeling in regard to this part of the subject; and that voluntary, philanthropic, and religious zeal, in co-partnership with medical skill and medical philanthropy, will find means by which far more good can be accomplished than by any compulsory laws." As we cannot agree with the right honourable gentleman in believing

that the Acts will be repealed, and that we shall have an opportunity of seeing his day dream fulfilled, we may profitably take a view of the past and present condition of matters as regards voluntary lock hospitals: and as charity begins at home, though it does not end there, we would respectfully call Mr. Stansfeld's attention to the county of Yorkshire, with its ten members for the three ridings and thirty-one for the boroughs. Now, it is remarkable that Yorkshire furnishes a large contingent of opponents to the Acts, among them being, in addition to Mr. Stansfeld, the Right Honourable W. E. Forster, Sir Harcourt Johnstone, Mr. Mundella, Mr. W. H. Gladstone, and other less prominent members. It is still more remarkable that Yorkshire does not possess a single lock hospital nor one lock ward in any of its general hospitals. In the Hull General Infirmary, a few cases of venereal disease are admitted yearly, and isolated as much as possible. Cases are also admitted into the Sheffield Public Hospital: but with these exceptions, such cases are excluded from Yorkshire hospitals. It is now nearly eight years since the first attempt was made to ensure the repeal of these Acts, during the whole of which interval the most active opposition has been going on, and large sums of money have been spent, and yet lock hospitals are as conspicuous by their absence in Yorkshire as they were then. Now we must be frank with our readers and the public, and truth compels us to state that only very little good can be effected by voluntary lock hospitals; the exhaustive inquiries into this subject by the late Mr. Acton, by Mr. James Lane, and by Mr. Berkeley Hill, all showing conclusively that prostitutes will not enter hospital until seriously diseased, and will too often leave long before they are cured. Still, it is open to the opponents of the Acts, who hold a contrary opinion, to prove their sincerity in a very practical manner by establishing at least one lock hospital in a locality where it is greatly needed. We would suggest the seaport of Hull, which has been shown to be a hot-bed of venereal disease, especially syphilis. No doubt the members we have named will contribute liberally, and have the hearty co-operation of many others. It will be all needed, since there is no more severe test of clarity than that which is represented by a lock hospital. It was the absence of voluntary lock hospitals, and the persistent refusal of the governors of general hospitals to admit women with venereal disease, which compelled the Government to establish those in Aldershot, Chatham, Colchester, Portsmouth, Devonport, etc.; the number of beds in which, now amounting to six hundred and forty-six, is far greater than those provided in all the voluntary lock hospitals of the three kingdoms. We trust that the foregoing facts will receive due attention in the forthcoming debate on the 22nd instant.

#### DO BACTERIA EXIST IN LIVING ANIMALS?

In the able lectures on the Infective Processes of Disease, delivered this year by Dr. Burdon Sanderson as Brown Professor, and published in January in the columns of the BRITISH MEDICAL JOURNAL, he quoted and appeared to confirm the experiments of Dr. Tiegel, of which he accepted the conclusion, that bacterial germs exist in the interior of the glandular organs of healthy animals during life. The question is one of the highest scientific interest, and of direct application to the principles and practice of antiseptic surgery; since, if wounds are liable to bacterial contamination from within, the basis of antiseptic precautions addressed *ad externum* is very sensibly weakened. Mr. Chiene of Edinburgh and Dr. Ewart of University College have, therefore, repeated Tiegel and Sanderson's experiments under *anti-septic* precautions of a simple kind; the result is to show, both by negative results and by severe test experiments, that in the organs of healthy rabbits, removed immediately after death with antiseptic precaution, no bacteria are found, and that it may fairly be concluded that neither bacteria nor their germs exist in the healthy organs of the animal during life. By way of indicating the relation of their researches to the germ-theory, the authors of the research point out that if neither bacteria nor their germs are contained in the healthy blood, milk, or other secretions (as Professor Lister

has proved in his address, published in the BRITISH MEDICAL JOURNAL of October 6th, 1877); nor in the healthy liver, spleen, kidneys, pancreas, lymphatic and other glands, as the present researches seem to prove—then there is no possible channel left through which bacteria can reach a wound from within; so that, in order to prevent putrefaction and the evils which follow it, it is only necessary to adopt an antiseptic method which will prevent living bacteria or their germs from entering the wound from without.

#### INQUESTS.

WE learn from the recently published quarterly return of the Registrar-General that during the first quarter of this year, 6,785 inquest cases were registered in England and Wales, being equal to 4.9 per cent. of the total deaths; the proportion was smaller than in any quarter since the first of 1872. In the twenty large towns, the proportion of inquest cases averaged 6.0 per cent., against 6.2 per cent. in the corresponding period of 1877, and ranged from 2.6 and 2.8 per cent. in Brighton and Sheffield, to 8.0 per cent. in Birmingham and Leicester, and 9.4 per cent. in Manchester. The fact that only 2.8 per cent. of inquests were held in Sheffield, whereas the proportion was 6.3 per cent. in Leeds, is only reconcilable on the assumption that either too few inquests are held in Sheffield, or that the number in Leeds is unnecessarily large. As bearing directly upon these wide variations in the proportions of inquests held, it may be noted that in Leeds last quarter the proportion of *uncertified deaths*, that is, of deaths registered without the production of a certificate either from a registered medical practitioner or a coroner, did not exceed 3.0 per cent., whereas it was equal to 6.9 per cent. in Sheffield. The registration of deaths without the production of certificates of their causes, affords dangerous facilities to conceal negligence, if not crime.

#### LEAD-POISONING BY FLOUR.

DR. ALFORD, in his report on the Taunton Rural Sanitary District, details the particulars of a local outbreak of lead-poisoning for which he could not account, as it occurred in the same part of his district, but in houses far apart. He analysed the water, cyder, preserved fruits, etc., but without detecting any lead; but, on careful inquiry, he found that the families had one thing in common—viz., they all had their flour from the same mill. An analysis of the flour showed the presence of lead; and, on going to the mill, he ascertained that, during the miller's absence, the holes in the stones had been filled up with lead. Of course the lead was removed, and the disease gradually disappeared. Some of the cases were of a very severe form; and it appeared, on further inquiry, that this is a practice of by no means uncommon occurrence; so that, especially in country districts, this source of lead-poisoning must not be forgotten.

#### SIR EVERARD HOME ON INTRAVENOUS INJECTION OF MEDICINAL AGENTS.

DR. GOODBRAKE writes to the *Chicago Medical Journal and Examiner*:—I have thought the enclosed scrap, taken from the *Pittsburgh Gazette* of July 7th, 1878, might be of sufficient interest to deserve a place in the *Journal and Examiner*.

"*Interesting Discovery.*—In the history of medicine, since the discovery of the circulation of the blood by Dr. Harvey, we have not heard of any of equal importance, except a discovery lately made in England by Sir Everard Home, which will most probably overturn the whole of the present practice in medicine. It has been a prevailing idea that a drop of any fluid introduced or injected into any of the veins produces immediate coagulation of the blood; but Sir Edward Home has ascertained by repeated experiments that medicines directly injected or introduced into the veins produce their effects more rapidly, with more benefit, and with less injury to the system, than when they are swallowed and then pass from the stomach into the circulation. Sir Everard Home has ascertained, not only from experiments made upon himself, but upon many others, that a *vinous infusion* of the *calceolium autumnale* or *meadow saffron*, injected into the vein of the ankle or leg, will cure the most violent gout. Sir Everard states that he completely recovered from a most violent attack of the gout in less

than twenty hours by injecting into the circulation sixty drops of this medicine. Sir Everard mentions that infusions of ipecacuanha and jalap, injected into the jugular vein, produced their respective effects of vomiting and purging much more rapidly, and with more ease to the patient, than when taken by the mouth. An infusion of rhubarb, when injected, causes a profuse flow of urine. In short, according to the experiments of Sir Everard Home, all medicines whatever act better, and are less injurious to the constitution, when injected into the veins than when swallowed by the mouth. Although the reputation of Sir Everard Home in the science of medicine is of the first rank, yet we would wish to have more satisfactory evidence of the effect of his practice before we should recommend a trial of it. We have no doubt that all those sciences immediately connected with the animal and vegetable kingdoms are yet in their infancy, and that great improvements will be made before the *lapse of many years*."

#### THE MORBID ANATOMY OF TETANUS.

DR. E. AUFRECHT of Magdeburg (*Deutsche Medicin. Wochenschrift*, April 8th) gives an excellent account of the morbid appearances found in the spinal cord of a case of tetanus. The patient, a labourer aged 41, got a compound dislocation of the thumb, which was treated by Lister's method. Eight days afterwards, spasm of the muscles of the jaw and neck set in, for which Dr. Hagedorn stretched the median nerve, but with no good result, as the patient died two days after the first appearance of the tetanic symptoms. At the *post mortem* examination, the sac of the spinal dura mater contained a considerable quantity of serum, and the cord, both grey and white matter, was obviously hyperæmic. After hardening for three months in a solution of bichromate of potash, which was changed every day or every second day, sections were made and carefully examined with the microscope. Throughout the cord, the vessels were found distended with red blood-corpuscles; this hyperæmia involved arteries, veins, and capillaries, as was proved by careful isolation. Around the larger vessels, especially in the lumbar region, there were found masses of a hyaline-looking substance, which appeared either dull or with short bright transverse striation. This material adhered to the adventitia, even when the vessels were isolated. He is inclined to regard this material as fibrin, but is bound to point out that it was present also in the cavity of the central canal. More frequently, dark granules of pigment and fatty-looking molecules were present in the adventitia. In the white substance, he found many granules of pigment, etc., and many of the nerve-fibres had fine granules in their medullary sheaths, which gave these latter a dusty appearance. The most marked changes were found in the cells, those of the cervical region having the lesion most pronounced, while, on passing down the cord to the lumbar region, the departure from the normal became less and less, although even in the latter region the morbid appearances were still manifest. These alterations were diminution in the size of the cells, increase of pigment, loss of their processes, disappearance of nuclei and nucleoli, the cells becoming of a diffuse yellow colour and containing refractile drops, or looking like structureless yellow lumps. The cells of the anterior horns of the lumbar region were quite normal, except perhaps a slight excess of pigmentation; those of the posterior horns were in various stages of degeneration. In the cervical region, not one single normal cell could be seen; they were represented by rust-coloured lumps without nuclei, nucleoli, or processes. In addition to the changes in the cells themselves, the grey matter contained many fine granules and coarser angular coloured grains, which quite resembled the pigment-grains of the cells. These were grouped especially round the central canal, which seemed wider in the cervical region. The epithelium of the central canal was normal, but the lumen was in many places narrowed: an appearance, he believes, not due to his mode of preparation. There were also around the central canal many globular bodies without any contour, which resembled oil-globules. Dr. Aufrecht compares these appearances with those described by Lockhart Clarke, W. H. Dickinson, and Tyson. He agrees with Lockhart Clarke in describing the change in the cells as granular degeneration; but differs from him in so far as he is rather inclined

to regard their cell-changes as primary; in fact, as a parenchymatous inflammation analogous to what takes place in the cells of the liver and of the sympathetic ganglion, and not as secondary to the vascular disturbance. He is by no means sure that the masses around the vessels were really fibrin, but is disposed to consider them colloid. This part of the paper seems rather weak, and we are by no means convinced by his arguments; for instance, he contends that, as the hyperæmia extended for the whole length of the cord, while the changes in the parenchyma diminished in their intensity in passing downwards, therefore there was no relation between the two; that the granules were not numerous around the vessels; and that some of the fibrin-looking material lay in the central canal. He contends that there is nothing characteristic of tetanus in this material, as Hayem found it in two cases of acute diffuse central myelitis. This we should not dispute, as we rarely expect to find anything characteristic in the nature of an exudation. Dr. Aufrecht's observations are an important addition to our knowledge of the morbid changes in tetanus, and go to support the view that the lesion consists in an acute diffuse central myelitis.

#### RESUSCITATION OF THE APPARENTLY DROWNED.

THE following letter has been addressed to the Royal Medical and Chirurgical Society by the Royal Humane Society.

"Royal Humane Society, 4, Trafalgar Square, March 30th, 1878.

"Sir,—I am instructed by the Committee of this Society to write and request that the Royal Medical and Chirurgical Society will favour them by reappointing the Council or Committee (which some years since, at the request of this Society, inquired into the various methods of treating the apparently drowned, and which resulted in the recommendation of a modified Silvester system, as now used and circulated by this institution), with a view to inquiring into, and, if advisable, recommending the adoption of, the new method recently brought before the public by Dr. B. Howard of New York, and with which I believe you are acquainted. This method was exhibited at the Society's receiving-house on Thursday last, and the many professional and other gentlemen then present thought it advisable to obtain, if possible, from your learned body an authoritative opinion of the merits of this new method, so clearly brought forward by Dr. Howard. I believe that Dr. Howard will be glad to attend any meeting of your learned Society, so as to answer any questions you may wish to put, or to demonstrate his plan. Trusting that an early reply may be given, so that action may be taken before Dr. Howard leaves Europe, I have the honour to be, sir, your obedient servant,

"(Signed) LAMBTON YOUNG, Secretary.

"The Secretary of the Royal Medical and Chirurgical Society."

In accordance with this request, we learn that a Committee has been appointed by the Royal Medical and Chirurgical Society, consisting of some of the surviving members of the old Committee appointed on this subject in 1862, and others, as follows: Professors Lister, Burdon Sanderson, and Curnow; Drs. Seveking, Lauder Brunton, Andrew, Ralfe, John Williams, and George Harley.

#### GUY'S HOSPITAL.

THE biennial dinner of this medical school was held at Willis's Rooms on Tuesday last, when Mr. Thomas Bryant occupied the chair, and was supported by Mr. Lushington (the Treasurer), Sir William Gull, Dr. Owen Rees, Mr. Cock, and the members of the present staff of the hospital. About two hundred and twenty old Guy's men with their friends attended, and very pleasant and successful was the gathering. After some formal toasts, Dr. Spay and Mr. John Gill returned thanks for the Army, Navy, and Reserve Forces; the latter gentleman having but recently returned from Turkey, where he was engaged during the late campaign as a medical officer in the Sultan's army. Dr. Wilks, in proposing the toast of the President, Treasurer, and Governors of Guy's Hospital, mentioned how intimately the prosperity of the hospital was bound up with that of the medical school. The Treasurer replied. The Chairman, in an eloquent speech, proposed the toast of the evening, Prosperity to the School of Medicine and Surgery attached to Guy's Hospital; and Mr. Cock and Dr. Habershon replied. The former was received with cheers again and again renewed, and gave his

experience of the School at Guy's at its separation fifty years ago from St. Thomas's Hospital, and of its subsequent independent growth. Dr. Pavy proposed the Universities and Medical Corporations; to which Sir William Gull replied, observing that he thought there would come a day when there would be but one Corporation of Medicine. He concluded by proposing the Chairman's health, which was very heartily received by the company. Dr. Owen Rees proposed the Past and Present Students of Guy's Hospital; to which Dr. H. N. Davies replied on behalf of the past students, and Mr. P. Horrocks and Mr. W. C. James for the present students. The health of the Honorary Secretary (Mr. H. G. Howse) was then proposed by the Chairman, and heartily responded to, all present recognising how much the success of the meeting was due to his excellent organisation.

#### ST. JOHN'S AMBULANCE ASSOCIATION.

At a meeting held on Saturday last at the house of Dr. Sieveking, at which several of the metropolitan hospitals were represented, and also the Council of the Order of St. John, the following resolutions were passed.

"1. That each hospital in London forming an ambulance committee should endeavour to guarantee lecturers to the St. John's Ambulance classes in the metropolis.

"2. That the classes should be examined by the Government military instructors detailed for the Order by the Army Medical Department.

"3. That classes of men or women who have obtained certificates may be formed for further instruction under members of the hospital staff; the pupils to receive the further examination from special hospital examiners.

"4. That, in the event of war, in which England may be engaged, the hospitals, through their ambulance committees, will aid the Order in finding surgeons, dressers, and nurses for any field-hospital or train which it may send out in support of the Army Medical Department; and that the Order will employ no one from any hospital without reference to that hospital's ambulance committee."

It is proposed to form a Central Committee, consisting of the medical members of the St. John's Central Committee, with the addition of the chairman and secretary of the ambulance committee formed at the hospital. Several classes for instruction have been opened, of which one commences in Albany Street on the 20th instant, under the direction of Mr. Edmund Owen of St. Mary's Hospital.

#### EMPHYSEMA AS AN AID TO OPERATION.

DR. BOUREL RONCIRE (*Archives de Méd. Nat.*, No. 2, 1878) describes a method of blowing air into the subcutaneous and intermuscular tissue, with the effect of dissociating and isolating the different layers and the superficial tissues, and with the object of facilitating surgical operations. It is employed at the hospital at Buenos Ayres, and is effected thus. In the vicinity of the tumour, the skin is perforated with a trocar; and to the cannula is attached an air-pump. The tissues in the neighbourhood are compressed to prevent undue diffusion of the emphysema; and the air is driven in by a few strokes of the piston in quantity sufficient to distend the surrounding cellular tissue and dissociate the various layers. The enucleation of tumours and the discovery of the vessels are said to be much facilitated by the process, which is described as being free from bad results. It has been employed in a large number of important operations: strangulated hernia, removal of cervical and submaxillary and axillary adenomata, ligation of large vessels, etc.

### SCOTLAND.

#### GLASGOW MILK-SUPPLY.

THE Glasgow Town Council have had prepared a Bill to regulate the milk supply and to amend the "Sale of Food and Drugs Act, 1875", and have remitted to their Parliamentary Bills Committee to adopt the necessary steps for getting the Bill introduced into the House of Commons by a private member of Parliament, with a view to legislation on the subject, in session if possible.

#### THE WATER-SUPPLY OF ARBROATH.

A SERIOUS interruption has occurred to the water-supply of Arbroath. The water is pumped up from a deep well in the neighbourhood, and although there is a double set of pumping gear, there is only one boiler, which is found to be leaky. On Thursday of last week, workmen began to repair the boiler, and the pumping in consequence had to be stopped; the quantity stored in the tank having become exhausted, the supply of water to the town ceased in the afternoon. The pumping was not resumed before Sunday.

#### FINE ART LOAN EXHIBITION AT GLASGOW.

LAST week, there was opened in Glasgow a Fine Art Loan Exhibition, the proceeds of which are to be devoted to the funds of the Royal Infirmary. That institution, owing to the competing claims to support of the recently established Western Hospital, to the dull state of trade, and to the unfortunate action taken by a certain section of the community in regard to the question of internal management and the religious denominations of the nurses, has suffered a diminution of income amounting last year to over £1,000. Under these circumstances, a number of public-spirited gentlemen, acting on a happy suggestion of one of their number, resolved to try if they could not at once raise a sum to provide against such deficiencies and promote the art education of the city, by bringing together a portion of the pictorial wealth known to exist in the private galleries of the west of Scotland. The enthusiasm of the promoters would seem to have been quite equalled by the generosity of the spirit in which they were met. Requiring only about five hundred pictures, they have had about a thousand to choose from. Not only so, but in many cases the owners of the works undertook the burden of insurance, the committee being only called upon to incur liability for £10,000, out of a total value of something like a quarter of a million. Many collectors went further, and delivered their pictures at the galleries free of charge. The result may be regarded as one of the most important exhibitions of the kind ever held north of the Tweed.

#### THE HEALTH OF SCOTLAND.

THE monthly return of the Registrar-General for Scotland, of the births, deaths, and marriages, registered in the eight principal towns of Scotland in April, has been issued. During the month, there were registered the births of 4,060 children; of whom 2,067 were males, and 1,993 females; 322 of these, or 7.9 per cent. of the whole, were illegitimate. The rate of illegitimacy varied in the different towns from 4 per cent. in Greenock to nearly 12 per cent. in Dundee. The deaths of 2,837 persons were registered. This mortality is at the annual rate of 23 per 1,000 persons in Greenock, which is the lowest, and 34 in Paisley, which has the highest percentage; 43 per cent. of the whole number of deaths were those of children under five years of age. The zymotic diseases proved fatal to 450 persons, constituting 15.9 per cent. of the total mortality. The prevalence and fatality of whooping-cough in Glasgow and in Aberdeen, of measles in Edinburgh and in Dundee, and of measles and diarrhoea in Leith, caused the above rate to be exceeded in each of these towns. Whooping-cough was the most fatal of the epidemics. The deaths from inflammatory diseases of the respiratory organs, not including consumption, whooping-cough, or croup, amounted to 28 per cent. of the whole mortality.

#### DEATH OF SIR JAMES COXE.

THE medical profession in Scotland has just lost one of its ablest members in the person of Sir James Cox, M.D., Commissioner in Lunacy, who died on Thursday, the 9th ult., at Folkestone, after a very short illness. He was on his way home from a tour on the continent, where he had been spending a short holiday from his official duties. Sir James was born in 1811, and took the degree of M.D. in the University of Edinburgh in 1824, after an extended medical and general education in Göttingen, Heidelberg, and Paris. He was appointed, in 1855, one of the members of a Royal Commission "to in-

quire into the condition of lunatic asylums in Scotland, and the existing state of the law in that country in reference to lunatics and lunatic asylums". The report of the Commissioners drawn up by Dr. Cox, and presented to Parliament in 1857, was an able document, and led to the passing in the same year of an Act establishing the General Board of Lunacy for Scotland, with Dr. Cox and Dr. W. A. F. Browne as Medical Commissioners. Since that time, he has been a most diligent and able member of the Board; and to him, in a great measure, are due its highly satisfactory working and valuable results. The honour of knighthood was conferred on him in 1863. Sir James was president of the Medico-Psychological Association in 1872, when it met in Edinburgh; and delivered an inaugural address, which was characterised by great boldness and breadth of view. His loss will be greatly felt by a very large circle of friends, medical and general, to whom he was endeared by many sterling qualities of head and heart.

#### DIAMOND ROCK-BORING.

ABOUT four months ago, it was stated that an attempt was being made to reach the deep water-bearing strata at the west of Edinburgh, for the purpose of furnishing a supply of an unlimited quantity of water to a large brewery. Success has attended the operations, which were conducted with the diamond rock-boring machinery. At the depth of six hundred and fifty-seven feet from the surface, water was tapped, and a supply of twenty gallons per minute, or twelve hundred gallons per hour, has been secured.

#### ABERDEEN HOSPITAL FOR SICK CHILDREN.

THE report of this institution, instituted only sixteen months since and already in a condition highly gratifying to its promoters, has just been issued; and states that, six months ago, the hospital was opened and immediately filled, so that the directors will now avail themselves of further accommodation at their disposal. The accounts show a favourable balance. The medical officers, Dr. W. E. Stephenson and Dr. R. J. Garden, to whom the thanks of the directors were given for their valuable services, received one hundred children as in-patients; of those, fifteen remained in the hospital. In the out-door department, 1,059 children had been treated.

#### ADULTERATION OF FOOD.

THE Glasgow city analysts report that, during the last quarter, they had made analyses of only four articles of food: two of sweet milk and two of confections, all of which were found to be genuine. It was pointed out that the very small number of samples which had been analysed was due to the dead-lock they had come to in regard to the administration and exposition of the law regarding the adulteration of food. It has been suggested that some amendment of the Adulteration Act may be got when the Council are putting before the legislature a short Bill, which is at present under the consideration of the Health Committee, to deal with the milk question.

#### THE DRAINAGE OF HAWICK.

THE drainage of this burgh has for several years engaged the attention of the Commissioners of Police, and various preliminary steps have been taken towards accomplishing the object in view. Surveys have been made and plans prepared, and, but for the difficulty of the disposal of the sewage, operations would have been begun long ago. It was at one time suggested to empty the sewage into the Teviot, at some distance below the town; but the plan met with so much opposition from various quarters that it had to be abandoned. Public feeling and the wisdom of Parliament having decided that the rivers were no longer to be regarded as the main sewers of the country, the Hawick Commissioners delayed proceeding with the drainage of the burgh till they should be advised as to, and employ, the best means of disposing of the sewage otherwise than by emptying it from one main outfall into the river. Recently the Board of Supervision has made strong representations on the subject to the Town Council, and they have been compelled to take the matter up in earnest. Messrs. Leslie C.E., were

instructed to prepare a scheme for the purification and disposal of the sewage; and the purification works on their plans have already been completed. The sewers are being laid in straight lines, having man-holes or lamp-holes at all the angles, which at once afford access to them and act as ventilators. The system of purification adopted by the engineers may be described as a combination of the best known means in operation elsewhere, viz., precipitation, assisted if necessary by lime and other chemicals, and land filtration. The main drain carries to the purification-works, in combination with the house sewage, the refuse scourings and washings from the factories and the spent liquids from the dyeworks. From the precipitating tanks the water is distributed over a field five acres in extent, collected again in deep drains, and finally allowed to fall into the river a mile below the town. The solid refuse is to be sold for manure. The cost of the whole works will be considerable, the present estimate being over £20,000.

### IRELAND.

TYPHUS fever is stated to be very prevalent in the Ballinasloe Union.

THE Marquis of Sligo has promised to secure a supply of water for Westport at his own expense.

ON last Saturday, a lunatic residing near Lurgan committed suicide by throwing himself under an engine on the Great Northern Railway; and, a couple of days afterwards, a woman who was subject to epileptic fits placed her neck on the rails in front of an approaching train, and was instantly killed.

#### RATHMINES MAIN-DRAINAGE.

THE Main Drainage Board of the Rathmines and Pembroke Townships, two important suburbs of Dublin, at a meeting held on the 7th instant, accepted a tender for constructing a main outfall and intercepting sewers at a cost of about £77,000.

#### SANITARY CONDITION OF ARDEE DISPENSARY DISTRICT.

DR. MOORE, sanitary officer, having reported unfavourably of the sanitary state of the town of Ardee and the surrounding district, the Local Government Board have recently drawn the attention of the guardians to the neglect of sanitary arrangements, and regret that they have not taken steps to remedy the evils complained of. They state that this important matter demands their prompt and effectual attention, the board, as the sanitary authority, being responsible for all questions relating to the sanitary condition of the town as well as other parts of the union. Dr. Moore remarks that there are no sanitary arrangements carried out in his district, and that the same condition of things remains as before the Sanitary Act came into operation.

#### RATHDOWN UNION.

AT a meeting of the Board of Guardians of this union last week, two additional cases of small-pox were reported from one of the union districts; and a complaint was made by one of the guardians that three patients had returned from Dublin as convalescent from the disease. It was pointed out that a prosecution could be instituted, and it was recommended that the clothes should be burned in such cases, the patients referred to having been brought into the workhouse hospital. It is a very serious matter to discharge small-pox patients from hospitals whilst they are liable to carry the infection to others, and it is one which, it is affirmed, has on more than one occasion occurred in the institutions which admit this class of cases in Dublin.

#### THE QUEEN'S UNIVERSITY IN IRELAND.

A VACANCY having occurred in the Senate of this University by the resignation of Mr. W. Mac Cormac of St. Thomas's Hospital, since appointed one of the University Examiners in Surgery, a movement has been instituted to endeavour to secure the seat for a representative

of the medical graduates:—as Mr. Mac Cormac was—in the person of Dr. W. Thornley Stoker. The large number of medical graduates in the University Corporation entitle them to adequate representation on its Senate. Dr. Thornley Stoker is a distinguished graduate of the University, and holds a high professional position; being Professor of Anatomy in the School of the Royal College of Surgeons, and Surgeon to the Richmond and to Swift's Hospitals. Dr. W. Thomson and Dr. Roe of Dublin are the Honorary Secretaries of Dr. Stoker's Committee. The next examinations in the Faculty of Medicine will be held in Dublin, commencing on June 3rd, and terminating on June 14th.

#### THE LIFFEY NUISANCE.

IN connection with the high death-rate of Dublin—which, not inclusive of the number of deaths from small pox, has existed for some weeks past—the extreme offensiveness of the atmosphere in the neighbourhood of this river is worth noting. Memorials complaining of the nuisance caused by the operations at the bridges in course of erection, and before alluded to by us, have been presented to the Public Health Committee. They, however, have been “referred on”, and reports subsequently received from engineers; but nothing, so far as we are aware, done in abatement. As showing the extremely polluted condition the bed of the river must be in, and the depth of filth lying on it, we may mention that the mud, etc., from the lowest excavation overlying the rock for the central coffer-dam for the new bridge, had a most offensive smell, and that the eyes of the workmen were affected by it in a remarkable manner.

#### THE ADELAIDE HOSPITAL.

THE vacant surgeoncy to this hospital caused by the retirement some months since of Mr. Albert Walsh, was filled on the 9th instant by the appointment thereto of Dr. Kendal Franks, the junior in point of professional standing of the several candidates. Dr. Franks graduated in medicine in 1875. He is a M.D. of the University of Dublin, Surgeon to the Throat and Ear Hospital, and Demonstrator of Anatomy and Private Teacher in the School of the Royal College of Surgeons.

#### LADY-DOCTORS.

AT the last monthly examinations of the King and Queen's College of Physicians in Ireland four ladies presented themselves; one for the final examination for the licence to practise medicine, and three for the previous examination. Mrs. Clark, who is a M.D. of the University of Berne, passed the final examination, and Miss Bartholomew the previous. The other two ladies were unsuccessful. Mrs. Clark also obtained the licence of the College to practise midwifery.

#### PHARMACEUTICAL SOCIETY OF IRELAND.

SIR DOMINIC CORRIGAN—to whose great exertions on behalf of this Society its establishment and present satisfactory condition are mainly due—having in consequence of his advancing years resigned its Presidency, the Council held a special meeting last week to elect his successor. Dr. Aquilla Smith, the Vice-President, who was proposed and seconded for the office, declined the honour, although quite willing to remain Vice-President, as he could not spare time for the efficient performance of the duties of the post. Accordingly, Mr. Tichborne, the well-known chemist, was unanimously elected President of the Society.

#### THE IRISH MEDICAL ASSOCIATION.

AT the last quarterly meeting of the Council of this Association, “The Medical Act, 1858, Amendment Bill” was taken into consideration. The Committee of Council had prepared a valuable document, embodying their “Observations” on the Bill; and these were, in the main, after full discussion, unanimously approved of. We have not space to give the text of the entire document, which bears evidence of acute and intelligent study of the Bill in all its points, and should be carefully studied by those anxious not to allow the present opportunity of ob-

taining satisfactory medical legislation slip. The two main reasons why the Council of the Association think that the Duke of Richmond's Bill cannot be considered as satisfactory are:

“1. That the Constitution of the General Medical Council is not affected by the Bill, while the General Medical Council, as at present constituted, only directly represents the Government and the Corporations, but scarcely at all the great bulk of the medical profession. That, while it is owing to the failure of the Corporations to adopt conjoint examinations, and the omission of the General Medical Council to enforce uniformity of examination and education, that the proposed legislation has become necessary, yet the regulation of examinations is to be almost altogether vested in the representatives of the licensing bodies. The Council of the Irish Medical Association consider that the Bill should provide for the direct representation of the great body of the profession in the General Medical Council; each division of the kingdom being duly represented.

“2. That the Bill does not make any efficient provision for uniformity of examination, and still leaves the nineteen portals open for admission to the *Register*. Experience has proved that a majority of the medical authorities are indisposed to unite for the promotion of conjoint examination schemes, and unless some power of compelling united action be provided in the Bill, there is no prospect of a single examining body being formed for each division of the United Kingdom.”

We are glad to know that the Council of the Irish Medical Association have warmly responded to the request of the Medical Reform Committee of the British Medical Association, to lend its powerful aid in amending this Bill.

#### BELFAST HOSPITAL FOR SICK CHILDREN.

IN a few months, it is intended to remove this institution to the new hospital now being erected in Queen Street. The cost, when completed, including furniture, will be somewhat over £5,000, of which sum £1,000 is still required; and the Board of Management hope that the affluent members of the community who sympathise with the work in which it is engaged will come to their assistance and contribute the necessary amount.

#### QUARTERLY REPORT OF THE HEALTH OF IRELAND.

DURING the December quarter of the past year, the births registered amounted to 31,278, being equal to an annual ratio of 1 in every 41.4, or 24.2 per 1,000 of the population; and the deaths to 21,802, affording an annual ratio of 1 in every 61.2, or 16.3 per 1,000. The deaths from the eight principal zymotic diseases numbered 2,181, or 10.0 per cent. of the total deaths registered, and 40.9 in every 100,000 of the population. Small-pox caused 11 deaths, all of which took place in Dublin; diphtheria, 70; fever, 571; diarrhoea, 407; and simple cholera, 9. The deaths from measles and its sequelæ amounted to 553, which, added to those in the previous quarters, make a total of 1,484 in the year; a mortality higher than that for any of the preceding ten years, and considerably over the annual average for that period. Scarlet fever caused 262 deaths, being 82 over that of the preceding quarter; and whooping-cough 298, this latter disease showing a gradual decline from the first quarter of the year. Erysipelas was epidemic in Larne District, Antrim, and prevailed in portions of Midleton Union, Cork, where some children, who had been recently vaccinated, were attacked with the disease. Sanitary matters do not show much improvement, as the complaints from registrars are numerous in reference to overcrowding, bad sewerage, impure water-supply, and general neglect of sanitary regulations in their various districts. The deaths of 18 persons were recorded as being 100 years of age and upwards, one woman's age, who died in Kenmare district, being returned as 114.

WEARDALE RURAL (Stanhope and Newlandisch)—Mr. Arnison commences his brief report by stating that there has not been any epidemic in the district during the year; that the death-rate was about 17 per 1,000, which is above the rate for 1876. The births had, however, increased, as they were 223, against 159 in the previous year. The district is reported as being in a good sanitary condition, and free from all serious diseases.

## POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

ON Tuesday, May 7th, the annual general meeting of the Poor-law Medical Officers' Association was held at the Freemasons' Tavern. Dr. JOSEPH ROGERS presided.

The CHAIRMAN, in an exhaustive address, laid before the meeting an account of the work done by the Council of the Association during the ten months since the last meeting in July 1877. He commenced by stating that, in consequence of the facilities afforded by Mr. Ernest Hart, the editor of the BRITISH MEDICAL JOURNAL, a large proportion of the work had already appeared in paragraph form. That very valuable assistance enabled them to send forth their views relating to Poor-law medical relief clothed with the editorial garb, and enabled them to influence by this means not only medical men, but the general public. After making this acknowledgment, he proceeded to give the details of the business of the Association, which may be briefly stated as follows. The Council had had a correspondence with the Local Government Board on the question of fees for operations, and the reply of the central board was published in the BRITISH MEDICAL JOURNAL of July 28th. In the same number were published a letter from a workhouse medical officer as to vexatious duties which were thrust upon him, and the advice tendered by the Council with good effect. On August 4th, a paragraph was inserted, drawing attention to the harsh treatment of Mr. Downes, a medical officer of forty years' standing and seventy-eight years of age, by the West Bromwich Board of Guardians, who refused superannuation. Sir Trevor Lawrence brought the fact to the notice of the President of the Local Government Board, who, by an inspector, urged the justice of the claim upon the guardians, but without effect. The next number of the JOURNAL drew attention to the maladministration of medical relief in the same Union. The paper on Poor-law Medical Relief, read by the Chairman at the Manchester meeting of the British Medical Association, was published on October 13th. That meeting was attended by the Guardians of the Manchester and adjacent unions, and the results, although not immediate, would ultimately be good. He had read papers on the subject at Plymouth, Newcastle, Norwich, Sheffield, Framlingham, Worcester, Edinburgh, and Manchester, in addition to delivering addresses in the metropolis. On October 6th, appeared a copy of a resolution passed by the Council, condemnatory of the proceedings of the Cardiff Board of Guardians towards Mr. James Milward, and thanking his colleagues for memorialising their Board in favour of him. In November, the Council again considered the case of Mr. Downes, and passed a resolution in reference to the action of Mr. Long, Local Government Board Inspector, and the general question of superannuation allowances. In the same month, the Council made representations to the Local Government Board on the question of granting increased facilities for making *post mortem* examinations in workhouses; but the Local Government Board refused to modify the almost prohibitory arrangements at present existing. The certification and removal to asylums of lunatics had also been considered by the Council, and reference was made to the case of the removal of a woman by the Chairman to Caterham, and the action of the Medical Superintendent thereon. In his (the Chairman's) opinion, this case proved the necessity that the profession generally should be better acquainted with pathological appearances. Mr. Bates had been assisted in resisting the treatment he experienced at the hands of an *ex officio* member of the Bridgend and Cowbridge Board of Guardians. Effective aid was also given to Mr. Powell in his dispute with the Bromyard Board of Guardians on medical extras. Subsequently, the Council interfered on hearing that the same board had made an appointment contrary to law; and the nearest patient of the gentleman appointed was five miles from his door and the furthest eleven, and there were medical men practising in the district. On the facts being laid before the Local Government Board, the appointment was cancelled. In March, the Council addressed a letter to the Local Government Board on the question of the refusal of the Saffron Walden Board of Guardians to pay a fee to Mr. Buck, for attending the child of a labourer who had sustained a fracture of the leg. The family of the man had previously received medical relief; but in this instance the medical officer did not obtain the usual order, and it was refused after his attendance had been given. This was, in the judgment of the Chairman, so important that he hoped some discussion would take place upon it. Other matters of minor importance had occupied the attention of the Council, and, although the matters stated comprised no small amount of labour, it gave but a very imperfect idea of the work done by Mr. Wickham Barnes, the Honorary Secretary, and Dr. Rogers, the Chairman of the Council, whose advice and assistance were sought by Poor-law medical officers in all parts of the country; and, in responding to such appeals,

they had been able to add greatly to the comfort of their less fortunately situated brethren.

At the request of the Chairman, Mr. Barnes read the reply of the Local Government Board to the letter of the Council in the case of Mr. Buck, which stated that the Board had no power to order the guardians to pay Mr. Buck a fee for his treatment of the child. He (Mr. Barnes) thought this was a very important case, and one which should be taken up; because, had Mr. Buck refused to attend the child, he would have been ruined in the estimation of the public.

The CHAIRMAN stated that he had been informed that when the Local Government Board Inspector waited upon the Board of Guardians in reference to the matter, the relieving officer was called in, but not Mr. Buck.

Mr. BALDING asked whether the Local Government Board made any order for attendance in urgent cases.

Mr. CORNWALL said a medical officer had no right to attend any case without an order.

Mr. YOUNG remarked that the state of the law justified them in abstaining from having anything to do with a case in which an order was not given. They might just do something to make the sufferer comfortable by putting an injured limb in the best position.

Mr. JACKSON said people with more than 16s., or even 30s. a-week, were considered fit cases to receive medical relief in Birmingham.

The CHAIRMAN suggested that he and the Secretary should be instructed to request Dr. Lush to bring the matter under the notice of Parliament by a question to Mr. Sclater-Booth.

Mr. CORNWALL suggested that this case should be supported by as many others as they could gather.

The CHAIRMAN said he would be happy to communicate such cases to Dr. Lush; but the rules of the House of Commons would prevent their being put forward when the question was asked on Mr. Buck's case.

After some further discussion, the suggestion of the Chairman was approved.

*Officers.*—The next business brought before the meeting was the election of officers for the ensuing year. Dr. Lush, M.P., was re-elected President of the Association; the Vice-President, the Council, and the Honorary Secretary were also re-elected.

The *Financial Statement* was presented; and from it it appeared that there was an available balance at the bankers' of over £30.

*Votes of Thanks.*—On the motion of Mr. CORNWALL, a vote of thanks was passed to the editors of the medical journals for the assistance they had given the Association in reporting their proceedings from time to time.—The thanks of the meeting were also given to the officers for their services during the past year.

*Alleged Neglect.*—Dr. GARLAND of Yeovil stated that some time since a charge of neglect made against him, of neglecting a patient, was fully investigated, and he was exonerated from blame; since then, the case was brought up again, and he was asked to attend again with his witnesses. He wished to know if he would be justified in refusing to do so, but to offer any further information required by letter.

An opinion was generally expressed that Dr. Garland should decline to reopen the case; but no resolution was passed upon it.

*Increase of the Association.*—Dr. E. DIVER spoke at some length on the means for increasing the number of members and improving the status of the Association. He said they ought to hold such a position that the President of the Local Government Board would think it an honour to come to the Association dinner.

Mr. BARNES said there was a great difficulty in carrying out what Dr. Diver suggested, owing to various causes, one being the apathy that existed among the Poor-law medical officers.

The CHAIRMAN said that all the steps Dr. Diver had suggested that they should take had already been taken. He found great difficulty in obtaining any change in the Poor-law system, as was shown in the agitation of 1864. He had hoped that the improvement made in London would have been extended to the country, but when he proposed it it was coldly met.

Mr. BALDING said they were labouring under a difficulty in having to deal with a sort of unknown body. If they could deal directly with the President of the Local Government Board, he would be more ready to listen to them.

In a discussion which followed, the opinions of members were very favourable to an alteration of the law to make the allowance of pensions by boards of guardians to medical officers compulsory; but no resolution was passed upon the matter.

This concluded the business of the meeting.

*Dinner.*—In the evening, the members and friends dined together, under the presidency of the Chairman. Among the guests were Mr. Ernest Hart and the Rev. James Williams, Vicar of Cranwell. A few

the usual loyal toasts, the CHAIRMAN proposed the health of Mr. Ernest Hart, to whom, he said, was due the initiation of the famous inquiry into the condition of the Metropolitan workhouse infirmaries, which was carried through with the assistance of Dr. Anstie and Dr. Carr, and subsequently the formation of the Workhouse Infirmaries' Association, which obtained from Parliament Mr. Hardy's Act, the Magna Charta of Poor-law medical reform; and ever since he had continued to render the most willing and valuable aid to the Poor-law medical officers and to this Association.—Mr. HART, in replying, said the metropolitan asylums, which were now the boast of London, were modelled precisely upon the lines of Poor-law medical reform, which he had laid down in a paper in the *Fortnightly Review*, entitled "The Hospitals of the State", of which five thousand copies were reprinted, partly at the expense of Mr. John Storr, a valued friend of this and all social reform, to whom he had been introduced by Dr. Rogers. Dr. Rogers had devoted energy and talents, which would have adorned the highest positions in this or any profession, to the service of the poor and the promotion of Poor-law reform. His life-long labours had conferred inestimable benefits on the sick poor and on his profession, and deserved perpetual memory. The powers of association were very great, and if this Association selected and defined its programme it could hardly over estimate its capacity for good.—The indefatigable services of Mr. Wickham Barnes, and the public-spirited and self-denying activity on behalf of the Association of Mr. Cornwall and Dr. Pinder, and others who gave much time to the Association, were subsequently mentioned with due honour.—Regret was expressed that the meetings were not more numerous attended.

### THE MEDICAL ACTS AMENDMENT BILL.

THE Medical Reform Committee have drawn up the subjoined petition which has been placed in the hands of the Duke of Westminster, K.G., for presentation to the House of Lords.

*Unto the Right Honourable the Lords Spiritual and Temporal of the United Kingdom of Great Britain and Ireland in Parliament assembled.*

The humble petition of the Medical Reform Committee of the British Medical Association sheweth—

That a Bill, intitled an Act to amend the Medical Act, 1858, has been brought into your Right Honourable House.

That, in that Bill, no provision is made for the introduction of direct representatives of the profession in the General Medical Council.

That the Bill does not provide compulsory enactments for the establishment of a conjoint board, for the examination of medical candidates in each division of the kingdom, on the principle of equal fees and equal examinations; and that such enactments are indispensable, in the interests of the public, to abolish the competition downwards in the granting of medical licences and diplomas.

That the British Medical Association numbers upwards of seven thousand members of the medical profession, and comprises a large proportion of the physicians and surgeons of the public hospitals and of the professors and lecturers attached to various schools of medicine throughout the kingdom.

That the British Medical Association has always occupied a prominent and influential position with respect to medical reform, and that the Medical Reform Act of 1858 was, in great measure, due to the efforts of the Association.

That, notwithstanding the passing of that Act twenty years ago, many grave defects still exist in the granting of qualifications to members of the profession.

That there are at present nineteen universities and medical and surgical corporations in the United Kingdom, each of which is empowered to grant one or more qualifications, each qualification entitling the possessor to be placed on the *Medical Register* as a legally qualified practitioner, and thereby enabling him to practise all departments of the medical profession, although possibly only qualified in one.

That the requirements of the various universities and corporations from candidates vary greatly in extent and character, and that an unworthy competition exists in the granting of degrees and licences; and candidates rejected by one examining board are known to have succeeded, without further study, in obtaining the licence of some other board of less stringent requirements.

That candidates who have obtained the degrees of Doctor of Medicine and other qualifications have, when seeking medical appointments in the army and navy, been frequently rejected by the Government examining boards for those services.

That the fee charged for granting diplomas ranges from half a guinea to more than a hundred times that amount.

That the General Medical Council, as now constituted, consists of seventeen members, who represent the several universities, medical and surgical corporations, and licensing bodies of the United Kingdom, and of six members nominated by the Crown, together with a President chosen by the other members of the Council.

That the great majority of the members nominated by the Crown are intimately connected with the universities and corporations, and that there is no direct connection between the General Medical Council and the general body of the registered members of the profession.

That, owing to the medical practitioners having no direct representatives in the Council, the profession evinces but little interest in its proceedings—a disadvantage which has been admitted in the debates of the Council.

That the representatives of the universities and corporations in the General Medical Council are not paid by the bodies which they represent, but out of a fund provided by the general body of the profession, which is unrepresented therein.

That the introduction into the General Medical Council of representatives elected by the profession would give the profession more confidence in the Council than at present, and would also add to the knowledge of the Council with respect to the needs of the public and of the profession in medical education, medical jurisprudence, and Poor-law medical relief, and would tend to balance the present overwhelming influence of corporation representatives.

That the demand for direct representation of the profession in the General Medical Council is in accordance with the almost unanimous voice of the profession.

That at each annual meeting of the Association held since 1866, as in Dublin in 1867, in Oxford in 1868, in Leeds in 1869, in Newcastle in 1870, in Plymouth in 1871, and in Birmingham in 1872, as well as at a special general meeting of the Association held in London in May 1870, for the express purpose of considering medical reform, resolutions were passed, with scarcely a dissentient voice, in favour of the necessity of direct representation, and the Association and the profession continue to demand it.

Your petitioners pray your Right Honourable House not to pass that, or any other Bill, unless provision be therein made for direct representation of the profession in the General Medical Council, and for the compulsory establishment of conjoint boards of examination, on the principle of equal fees and equal examinations in each division of the kingdom.

And your petitioners will ever pray, etc.

EDWARD WATERS, M.D., Ex-President of the British Medical Association, Chairman of the Medical Reform Committee of the British Medical Association.

Chester, May 14th, 1878.

### COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

THE forthcoming election of Fellows into the Council of the above institution has brought an unprecedented number of candidates already into the field to fill the three vacant seats which will be caused by the retirement, in the prescribed order, of Mr. Erasmus Wilson, F.R.S., Mr. Henry Lee, and Mr. Barnard Holt. These gentlemen, it is understood, will offer themselves for re-election; they will be opposed by the following fresh candidates, whose names we publish in the order of seniority of fellowship; viz., Mr. Joseph Lister, F.R.S., now of King's College, December 9th, 1852; Sir Henry Thompson, of University College, November 10th, 1853; Mr. John Wood, F.R.S., of King's College, May 11th, 1854; Mr. Henry Power, of St. Bartholomew's Hospital, December 1st, 1854; Mr. Edward Lund of the Manchester Infirmary, June 12th, 1863; and Mr. John Gay, a late member of the Council, who lost his re-election last year by only a few votes, much to the regret of many of his colleagues in the Council and of friends outside. We have always, however, contended that seniority in the College should rank from the date of membership, and this gives to Sir Henry Thompson undoubted seniority, since he became member, we believe, in 1848, and obtained the Jacksonian Prize in 1852, before Mr. Lister became connected with the College. Sir Henry Thompson has twice received the Jacksonian Prize of the College. As already stated, nine candidates to fill three vacancies in the Council of the Royal College of Surgeons is an unprecedented event; and, as if this be not enough, the names of two more gentlemen have been mentioned. The gentlemen whose names appear in *italics* in the above list are members of the Board of Examiners.

## UNIVERSITY OF LONDON.

THE annual meeting of Convocation of the University of London was held on Tuesday last; Dr. STORRAR in the chair. At the commencement of the proceedings, Dr. Carpenter laid on the table the new supplemental charter. On the motion of the Chairman, this charter, bearing date the 4th of May, was accepted. Dr. Pye-Smith having moved "That the report of the Annual Committee be received", and Dr. M. Baines having seconded the motion, Mr. A. P. Hensman said the question had arisen whether it was not desirable that the House should have some independent power. A strong feeling had, he remarked, been evinced in favour of such a change. Convocation consisted of about one thousand six hundred members, filling various positions in life; and, in his opinion, it was time that such a body should possess greater powers.

The report having been received, Dr. Pye-Smith moved the adoption of the following resolution, recommended in paragraph 9 of the report: "That, while Convocation recognises the advantage of examinations conducted by a body independent of the teachers of the candidates for degrees, it also recognises the fact that examinations exercise an important influence on the course of study pursued in the institutions where the candidates for degrees are chiefly educated; and that, with the view of creating and preserving a harmony between the requirements of the University and the course of study pursued in those institutions, it is expedient that they should be brought into closer connection with the Senate."—Dr. M. Baines seconded the resolution, and it was adopted almost unanimously.

Mr. John Hennell proposed on behalf of Mr. J. Anstie, who was absent, the adoption of the following resolution, recommended in paragraph 11 of the report: "That, with this object, it is desirable for the Senate to exercise its power under the present charter of revising the list of affiliated colleges, and from time to time of admitting to or excluding from this list, according to the position taken by these colleges at the University examinations for degrees, and on such other grounds as the Senate may in each case determine." The motion, having been seconded by Mr. J. W. Bone, was opposed by Mr. A. B. Hopkins.—Mr. W. Shaen and Mr. A. K. Rollett supported the resolution.—Dr. Grece moved the previous question, and Mr. Hensman seconded this amendment.—Mr. R. H. Hutton felt that the resolution was right in principle, though there might be difficulties in carrying it out.—After some discussion, the amendment was negatived, and the resolution was then adopted.

On the motion of Mr. A. McDowall, it was resolved, after a short discussion: "That it would be desirable that the educating bodies included in the revised list should be invited to communicate, by delegates or in writing, with the Senate, and that facilities should be afforded to such delegates of deliberating together, and of communicating with the Senate, especially on the subject of examinations."

On the motion of Dr. Weymouth, seconded by Mr. Murch, it was further resolved: "That it is desirable for the examiners of the University, either in faculties or collectively, to form a board, one of whose functions would be to consider and report upon any subject connected with the examinations which they might deem of importance to the University."

Dr. Pye-Smith moved, and the Rev. Josiah Miller seconded, the following: "That it is desirable that the University should take advantage of such opportunities as may present themselves of promoting, by the institution of University chairs or otherwise, the cultivation of such higher or less usual branches of study as can be more conveniently or more efficiently taught by a central body." Mr. R. N. Fowler opposed the motion on financial grounds, there being no funds, he observed, to carry out such an object.—After a long discussion, in which objections of the same kind and others of a different character were urged by several speakers, Mr. Cozens-Hardy moved the previous question. This having been seconded, after some discussion it was negatived by thirty-nine votes to twenty-three; after which the original resolution was adopted.

On the motion of Dr. E. B. Baxter, it was further resolved: "That it is desirable for the Senate to consider the importance of recognising independent research in the examinations for the higher degrees in such way as the Senate may approve."

On the motion of Mr. Magnus, it was resolved: "That it is desirable that in any new charter a clause should be inserted giving to the University the power of examining and inspecting schools"; and on that of Mr. W. Shaen: "That it is desirable that the graduates be represented in the Senate by a larger number of members nominated by Convocation."

The proceedings then terminated.

## DEATHS FROM ANÆSTHETICS.

IT is our painful duty to record this week two deaths from the administration of anæsthetics.

## CHLOROFORM IN DENTISTRY.

THE remarks which we last week made reprehending the use of chloroform in dentistry, *à propos* of two cases of death in the dentist's chair recently reported in America, have received an unexpected and painful application in London this week. On Saturday, the Coroner for West-Middlesex held an inquiry at Shafesbury House, High Street, Kensington, as to the death of Mary Dolores Dormer, aged 10, daughter of Mr. Herbert Francis Dormer. Mr. John Saxty Good, a dentist, of 17, Phillimore Place, Kensington, stated that on Thursday last Mrs. Dormer brought the child to him for the purpose of having some teeth taken out; and, at the special request of Mrs. Dormer, an anæsthetic was administered by Mr. Thrupp, who always assisted the witness. No examination was made as to the physical condition of the child previous to the operation, and Mrs. Dormer was not in the room. A mixture of ether and chloroform was used. The child did not struggle at all. As soon as she became sufficiently affected by the anæsthetic, the operation was performed. Three teeth were removed, when a shadow seemed to pass over the child's face. The usual remedies were applied for restoring her, but without avail. She died in a few minutes. Mr. James Godfrey Thrupp, 37, Elgin Road, Kensington, said he was a surgeon. He had made the administration of anæsthetics his particular study, having practised at St. George's Hospital for some years. The child appeared to be perfectly healthy, the heat of the body being normal. No examination was made by thermometer. About a drachm and a half of the anæsthetic was taken, and the child was reduced to a state of total insensibility. After the operation was finished, a change came over the child, and the witness knew by the symptoms that she was either going to vomit or die. The circulation of the blood suddenly failed, and death immediately ensued. The jury returned a verdict that death was caused by syncope from the administration of chloroform, and that the death was due to misadventure. It is painful to a lid to the distress to which so shocking a misadventure must, we apprehend, give rise; but we cannot help asking Mr. J. G. Thrupp whether, "having made anæsthetics his particular study", he has not long since arrived at the conclusion that peroxide of nitrogen is by far the safest anæsthetic for dental purposes; and what were the reasons which induced him to forego the safer anæsthetic and employ the more prolonged but more dangerous one. Mr. Thrupp is of course not unaware of the very strong views which were publicly expressed some time since by Mr. G. Pollock, an eminent and much esteemed teacher at St. George's, as to the grave responsibility which attaches to the use in any case of any other than the safest anæsthetic. Is it ever right to use chloroform for dental purposes? We wish the Odontological Society would pronounce an authoritative opinion on that subject; and we should hope that, if they were to do so, they would absolutely forbid it.

## STRANGULATED HERNIA: DEATH DURING THE ADMINISTRATION OF ETHER.

A COAL-PORTER, over fifty years of age, was admitted into the London Hospital for strangulated hernia last week. He was a well-developed man, and had been the subject of inguinal hernia more than three years, but till the last week had always been able to restrain it, and had never worn a truss. He had never experienced any special inconvenience from the rupture till four days before his admission to the hospital, when he was troubled with abdominal pain, complete obstruction of the bowels, and frequent vomiting, latterly becoming fecal. His general health had been failing in an increasing degree during the last few years, so that he had sought medical advice. When admitted to hospital, he complained much of abdominal pain, and was unable to reduce his rupture. When examined, he presented a large scrotal hernia, somewhat tense. During the examination, he began vomiting fecal matter. Taxis having been used, but the symptoms remaining unrelieved, it was considered advisable to place the man under an anæsthetic. The house-surgeon accordingly administered ether, using not more than an ounce and a half in all. The patient came under the influence of the ether rapidly, and without difficulty or adverse symptoms. The local examination was then proceeded with. The patient's respirations were perfectly regular, and his pulse good, when, about six minutes after inhalation began, a sudden spasmodic inspiratory sound was heard, as if he were choking. His tongue was immediately drawn forward with the forceps; but respiration had ceased, although his pulse continued to beat for another half-minute. Silvester's artificial respiration was employed, but no spontaneous in-

spiratory effort followed. During the artificial respiration, some fecal matter came up into the mouth. These efforts were continued a quarter of an hour, but proved useless. At the *post mortem* examination, the left ventricle was found contracted; but the heart appeared healthy. The lungs were extremely congested. There was fecal staining of the œsophagus and larynx, but no such matter had been drawn into the lungs. The liver was healthy. The kidneys were slightly granular, but not congested. The portion of small intestine which had been strangulated was about twenty inches in length, extremely congested, with commencing peritonitis upon its surface. It must be remembered that in such a case as this, where strangulation had existed four days and was attended with constant vomiting and a feeble circulation, there were many circumstances predisposing to death besides the administration of ether.

#### HARVEY TERCENTENARY MEMORIAL FUND.

WITH much pleasure we are able to announce the continued growth of this Fund, which now amounts to £1600. In order that the wishes of the promoters may be realised, there is needed now only a sum of about £400 more, which it is hoped will be shortly subscribed. Amongst the more recent contributions is a liberal donation of fifty guineas from the Royal Medical and Chirurgical Society. Mrs. Balderson has also given £25; the Harveian Society of London, ten guineas (second donation); Professor H. W. Acland, five guineas; Dr. Henri Guéneau de Mussy, five guineas; Mr. E. Lund, two guineas, etc. Subscriptions will be thankfully received by Sir George Burrows, Bart., or Mr. Prescott Hewett, the honorary treasurers; by Mr. George Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone, the honorary secretaries; or they may be paid in to the account of the Fund at the Western Branch of the Bank of England, Burlington Gardens, London, W.

#### EFFECTS OF DEPRIVATION OF WATER.

A VERY interesting and graphic account of the sufferings produced by deprivation of water is given in the *American Journal of the Medical Sciences* for April, by Dr. J. H. King, Captain and Assistant-Surgeon in the United States Army. The writer was one of the party sent in search of the lost men. It appears that on July 26th, Captain Nolan, Lieutenant Cooper, and forty troopers of a cavalry regiment, started in search of Indians in Texas. The guide, anxious to keep the Indian trail, neglected his landmarks, and could not find water in the evening. The scanty supply of water which had been taken in the men's canteens was exhausted in the early part of the march. Next day, the heat was excessive; a search for water was made in vain, and the men were becoming faint and exhausted.

"The next day found them still marching onwards, and the midday tropical heat causing great suffering. The desire for water now became uncontrollable. The most loathsome fluid would now have been accepted to moisten their swollen tongues and supply their inward craving. The salivary and mucous secretions had long been absent; their mouths and throats were so parched that they could not swallow the Government hard-bread; after being masticated, it accumulated between the teeth and in the palate, from whence it had to be extracted with the fingers; the same occurred with mesquite-beans and whatever else they attempted to eat. The sensibility of the lingual and buccal mucous membranes was so much impaired that they could not perceive when anything was in their mouths. The condition of the 'prime viæ' may in a degree be realised, when it is explained that brown sugar would not dissolve in their mouths, and that it was impossible for them to swallow it. Vertigo and dimness of vision affected all; they had difficulty in speaking, voices weak and strange-sounding; and they were troubled with deafness, appearing stupid to each other, questions having to be repeated several times before they could be understood; they were also very feeble and had a tottering gait. Many were delirious. What little sleep they were able to get was disturbed with ever-recurring dreams of banquets, feasts, and similar scenes, in which they were enjoying every kind of dainty food and delicious drink.

"At this stage they would in all likelihood have perished had they not resorted to the use of horse blood. As the animals gave out, they cut them open and drank their blood. The horses had been so long deprived of every kind of fluid that their blood was thick, and coagulated instantly on exposure; nevertheless, at the time it appeared more

delicious than anything they had ever tasted; in fact, every one was so eager to obtain it that discipline alone prevented them from struggling for more than the stinted share allowable to each. The heart and other viscera were grasped and sucked as if to secure even the semblance of moisture. At first they could not swallow the clotted blood, but had to hold it in their mouths, moving it to and fro between the teeth, until it became somewhat broken up, after which they were enabled to force it down their parched throats. This horse-blood quickly developed diarrhoea, passing through the bowels almost as soon as taken. Their own urine, which was very scanty and deep-coloured, they drank thankfully, first sweetening it with sugar. The inclination to urinate was absent, and micturition performed with difficulty. A few drank the horses' urine, although at times it was caught in cups and given to the animals themselves. They became oppressed with dyspnoea, and a feeling of suffocation as though the sides of the trachea were adhering, to relieve which they closed the lips and breathed through the nose, prolonging the intervals between each inspiration as much as possible. Gazing on each other, their lips thus closed were observed to be covered with a whitish, dry froth, and had a ghastly, pale, lifeless appearance, as though they would never be opened again. Their fingers and the palms of their hands looked shrivelled and pale; some who had removed their boots suffered from swollen feet and legs.

"The situation was now desperate, and feelings akin to despair took possession of them—suspicious ideas towards each other came over them, and they lost confidence in each other. They again saw the sun set, and another night was spent on these untrodden wastes, without alleviation of their misery. Persistent wakefulness now aggravated their mental anguish, and in vain at every halt they lay down and tried to sleep.

"Their deplorable condition continued to gradually grow worse, until 5 A.M., July 30th, 1877, when, providentially, part of the command succeeded in making 'Double Lakes'. At this time, a number of men were missing, some having been unable to keep up with the main column, while others had strayed after water."

The next morning, relief arrived. The condition of the men when seen is thus described by Dr. King:

"The demands of their systems were so imperative that the inclination to drink was irresistible; it seemed impossible to refrain from pouring down water, notwithstanding that their stomachs would not retain it. As they kept filling themselves with water, it was vomited up; the same thing occurred when they endeavoured to eat dry food. Warm coffee was the only thing they had that revived them at all, until after Captain Lee met them.

"Although water was imbibed again and again, even to repletion of the stomach, it did not assuage their insatiable thirst, thus demonstrating that the sense of thirst is, like the sense of hunger, located in the general system, and that it could not be relieved until the remote tissues were supplied. Moreover, the activity of this regenerating process was prevented by the deficiency of water in the absorbent vessels themselves. The same cause is competent to explain the overpowering dyspnoea, which threatened the existence of these men; for only moist membranes allow the free passage of gases which must take place in respiration. The lungs of these men were filled with the purest air, yet they appreciated an almost overwhelming sense of suffocation. Another point worthy of our attention is the loss these men must have sustained by integumentary and pulmonary exhalations. The mean daily exhalation of watery vapour in expired air, Valentin estimates at one and one-fifth pounds airdupois, and the daily loss by cutaneous transpiration at about two pounds; in the case before us, the quantities were influenced and increased by the conditions of temperature, exercise, etc.

"The superior endurance of the mule over the horse was obviously manifested on this scout. The horses' tongues were swollen, mouths and systems generally affected much in the same manner as the men's; they could not chew or swallow grass; many gave out completely. On the other hand, the mules, comparatively unfatigued, would crop the grass and graze at every halt.

"It is essential to remember that the sensations of thirst, to which these cavalymen almost succumbed, were intensified by the dry state of the atmosphere; they were toiling over arid plains and elevated plateaus in a climate noted for its lack of moisture.

"On August 1st, 1877, Captain Nolan heard that fourteen of his followers had managed to get all right as far as the Supply Camp. His total loss, therefore, after this disastrous scout, only consisted of two men dead and two missing, supposed to be dead."

MISS DE LISLE ALLEN, a daughter of the late Dr. de Lisle Allen, has devoted herself, with promise of success, to the musical profession, and will give her first concert at St. George's Hall, Langham Place, on Saturday, May 25th.

## ASSOCIATION INTELLIGENCE.

## METROPOLITAN COUNTIES BRANCH.

AN Ordinary Meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesday, May 22nd, at 8 P.M., when papers on Vaccination will be read by Dr. E. C. Seaton and Dr. J. Greene of Birmingham.

ALEXANDER HENRY, M.D. } *Honorary Secretaries.*  
W. CHAPMAN GRIGG, M.D. }

57, Doughty Street, W.C., May 13th, 1878.

## SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT MEETINGS.

THE next meeting of the above District will be held at Lewes, on Friday, May 24th, at 3.30 P.M.: N. P. BLAKER, Esq., of Brighton, in the Chair.

Dinner will be provided at 5.30 P.M.

Notice of intended communications is requested by the Secretary on or before Wednesday, the 14th instant, in order that they may be inserted in the usual circular.

THOMAS TROLLOPE, M.D., *Honorary Secretary.*

9, Maze Hill, St. Leonard's-on-Sea, May 7th, 1878.

## BATH AND BRISTOL BRANCH.

THE sixth ordinary meeting of the Session will be held at the Museum and Library, at the top of Park Street, Bristol, on Wednesday evening, May 29th, at half past Seven o'clock; H. MARSHALL, M.D., President.

The evening will be devoted to a discussion on Alcohol in Health and Disease, which will be introduced by Dr. E. L. Fox.

E. C. BOARD, } *Honorary Secretaries.*  
R. S. FOWLER, }

7, Caledonian Place, Clifton, May 14th, 1878.

## BORDER COUNTIES BRANCH.

THE spring meeting of this Branch will be held at the Keswick Hotel, Keswick, on Friday, June 7th: President—Dr. LOCKIE; President-elect—Dr. GILCHRIST.

Gentlemen intending to read papers, or to be present at the dinner, are requested to give notice to the Secretaries.

R. MACLAREN, M.D., Carlisle, } *Honorary Secretaries.*  
JOHN SMITH, M.D., Dumfries, }

Carlisle, May 11th, 1878.

## THAMES VALLEY BRANCH.

THE next general meeting will be held on June 13th, at the Greyhound Hotel, Richmond, at Six o'clock.

Papers will be read by—

1. Mr. Balmanno Squire: The Use of Chrysophanic Acid.

2. Dr. Trouncer:

3. Dr. Atkinson: Vaccination and Revaccination.

Dinner at the above hotel at Seven o'clock. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Honorary Secretary.*

Kingston-on-Thames, May 13th, 1878.

## EAST ANGLIAN BRANCH.

THE annual meeting of the above Branch will be held at Peterborough, on Friday, June 21st, at 11.30 A.M., in conjunction with the Cambridge and Huntingdon and South Midland Branches: THOMAS J. WALKER, M.D., President elect, in the Chair.

After Branch preliminary business at 11.30, there will be a general meeting about 12.15, when the President-elect will read an address; at the conclusion of which, he kindly invites members to luncheon at his house before the next general meeting at 2.15 P.M., for papers, discussions, etc.

Gentlemen wishing to read papers, or to dine, are requested to communicate as early as possible with one of the Honorary Secretaries.

WM. A. ELLISTON, M.D., Ipswich, } *Honorary Secretaries:*  
J. B. PITT, M.D., Norwich, }

Norwich, May 14th, 1878.

## STAFFORDSHIRE BRANCH.

THE third ordinary meeting of the Session will be held at the Mines' Drainage Office, 22, Darlington Street, Wolverhampton, on Thursday, May 30th, at 3 o'clock P.M.

VINCENT JACKSON, } *Honorary Secretaries.*  
J. G. U. WEST, }

Wolverhampton, May 5th, 1878.

## SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT MEETINGS.

THE next meeting of this District will take place at the Marine Hotel, Worthing, on Thursday, May 30th, at 3.15 P.M.: A. H. COLLET, Esq., in the Chair.

The dinner will be served at 5.30 P.M.

Notice of intended communications is requested by the Honorary Secretary on or before Tuesday, the 21st instant, for insertion in the circular convening the meeting.

WM. J. HARRIS, *Honorary Secretary.*

13, Marine Parade, Worthing, May 11th, 1878.

## MIDLAND BRANCH.

THE annual meeting of this Branch will be held at Lincoln, on Thursday, June 27th: President—C. H. MARRIOTT, M.D.; President-elect, A. MERCER ADAM, M.D.

Members desirous of reading papers are requested to communicate with

C. HARRISON, M.D., *Honorary Secretary.*

Lincoln, May 14th, 1878.

## NORTH OF ENGLAND BRANCH: SPRING MEETING.

THE spring meeting of this Branch was held in the Board Room of the Guardians, Hexham, on Thursday, April 25th; S. W. BROADBENT, Esq., President, in the chair. There were present twenty-eight members and three visitors.

*New Members.*—The following gentlemen, members of the Association, were duly elected members of the Branch: H. W. DAVIES, Esq., Jarrow-on-Tyne; Samuel Edwards, Esq., Tynhoe; Cottenham Farmer, Esq., Hexham; L. J. HOBSON, M.B., Newcastle-upon-Tyne; W. H. WALKER, M.D., Aldborough; Samuel Warren, M.B., Castle Elen.

*Habitual Drunkards Committee.*—The SECRETARY read the report of the Committee of the Association. It was moved by Dr. EASTWOOD, seconded by Mr. G. B. MORGAN, and carried by acclamation: "That Dr. Philipson be appointed to represent the Branch in the Committee."

*Harvey Tercentenary Memorial.*—The SECRETARY read a communication from the Central Committee. On the motion of the PRESIDENT, seconded by Dr. BYROM BRAMWELL, it was resolved that the sum of five guineas should be contributed by the Branch to the fund.

*Medical Reform and a Petition to Parliament.*—Dr. EASTWOOD introduced the question, and presented the petition to the House of Lords, which was duly signed by the President, the other officers, and the members.

*Papers.*—The following papers, &c., were read:

1. Drs. STAINTHORPE and FARMER: Case of Aortic Aneurism in a boy aged 13.

2. Drs. STAINTHORPE and FARMER: Case of Contracted Knee-Joint, recently operated on by Division of the Tendons and Forcible Extension.

3. Dr. BYROM BRAMWELL: On the Differential Diagnosis of Aortic Aneurisms and other Intrathoracic Tumours, with cases and specimens.

4. Dr. E. C. ANDERSON: On Leucine and Tyrosine, and their diagnostic value in disease, with cases.

5. Dr. JAMES MURPHY: Exhibition of Tarnier's Obstetric Forceps.

6. Dr. JAMES MURPHY: On Puerperal Convulsions.

7. Dr. J. C. MURRAY: Case of Difficult Instrumental Labour, from Deformed Pelvis.

8. Dr. M. W. BRADLEY: *Post Partum* Hemorrhage, with Notes of Three Cases successfully treated by Compression of the Abdominal Aorta.

9. Dr. PHILIPSON: Notes of a Case of Hematuria.

*Vote of Thanks.*—On the motion of the PRESIDENT, a hearty vote of thanks was accorded to the readers of papers, also to the Chairman and Guardians for the use of the room for the purposes of the meeting.

*Dinner.*—The members and their friends dined together at the White Hart Hotel. The President was supported on the right by the Rev. Canon Barker (Rector of Hexham), and on the left by Major Nicholson of Hexham. After the loyal and other customary toasts, the President gave the British Medical Association, and success to the North of England Branch, which was heartily received and warmly responded to. Other toasts followed, namely, that of the President, the President-Elect (Dr. Moore), the Honorary Secretary (Dr. Philipson), and Dr. Stainthorpe, to whom they were indebted for the admirable arrangements of the meeting and dinner.

## REPORTS OF SOCIETIES.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 3RD, 1878.

CHARLES WEST, M.D., F.R.C.P., President, in the Chair.

*Rupture of the Fetal Head.*—Dr. CORY showed a foetal head, with a rent situated on the left side of the coronal suture, through which brain-matter had escaped. The tear was at first supposed to have been produced by the forceps; but it was subsequently ascertained that the student in attendance had used a hair-pin to rupture the membranes, at which time the injury to the scalp had probably been produced. There was a tumour attached to the sacrum, which impeded delivery, and craniotomy would in all probability have had to be performed.

*Cancerous Polypi Removed during Pregnancy.*—Dr. GALABIN exhibited two specimens of cancerous polypi of the cervix uteri, which he had removed from pregnant women, and showed microscopical sections of them. Both specimens, he said, were instances of a somewhat rare combination of pathological products, viz., myoma and carcinoma. The smaller tumour, which was about the size of a Spanish chestnut, was removed by means of the galvanic cautery at the fourth month of pregnancy, the patient having suffered from excessive hæmorrhage. Delivery took place naturally at full term, since which there had been no trace of recurrence. The larger tumour was removed by the galvanic cautery at the eighth month of pregnancy, the patient being much reduced by continued hæmorrhage and persistent vomiting. Premature labour occurred twenty-four hours after the operation, the child presenting by the breech, and being lost from the slow yielding of the cervix. The patient apparently recovered, but died some months later, probably from some internal extension of the disease. The tumour appeared to have originated in an epithelioma, the nested masses being very distinct.

*Cystic Disease of the Fetal Kidney.*—Dr. GERVIS exhibited a specimen of this disease, from a case which had occurred in the practice of Dr. Fletcher of Earl Soham. Extreme difficulty was experienced in the delivery of the body of the foetus, and ultimately it was found necessary to eviscerate. Dr. Gervis had on previous occasions exhibited specimens of hydrometra and hydronephrosis, occurring in the foetus, as causes of difficult labour, but this was a specimen of a still rarer foetal disease.—In reply to Dr. HEYWOOD SMITH, Dr. Gervis said that, previously to her confinement, the mother had been in perfect health.

*Congenital Syphilis.*—Dr. WILTSHIRE exhibited a photograph of an infant aged five months, who came under his care at St. Mary's Hospital, with enormous enlargements of the shoulder-joints, hip-joints, and knee-joints. The swellings came on very rapidly, and fluctuation was distinct in them. The child was remarkably anæmic, and presented in his face and elsewhere signs of congenital syphilis. The abscesses were tapped with the aspirator, and a large quantity of pus was withdrawn. The child, however, died soon afterwards; and, at the *post mortem* examination, the affected joints were found to be disorganised and the epiphyses separated. The liver was the seat of an abscess, which was apparently due to the breaking down of a syphilitic gumma.

*Cancer of the Body of the Uterus.*—Dr. SQUIRE exhibited a specimen of cancer of the uterus, where carcinomatous degeneration had proceeded to its most extreme point without pain ever having been a marked symptom. A. B., aged 58, unmarried, began to suffer two years ago from a sanious vaginal discharge. This was arrested for a time by general tonics, but reappeared a few months later. Vaginal examination then showed the uterus and cervix to be small and perfectly movable. The patient felt quite well till a year ago, when febrile disturbance set in, with evening exacerbation. A resistance was felt in the right hypogastric region and tenderness was complained of there; the cervix was still movable and appeared healthy. The patient lost flesh. From these symptoms and the family history, cancer of the body of the uterus was diagnosed. During the last three months of life, phlebitis occurred

in each leg, and did not cease till a fortnight before death, when collapse set in. Fæces subsequently passed from the vagina, and the patient gradually sank. On *post mortem* examination, no secondary deposits were found in any viscera; there were no enlarged glands; the peritoneum was smooth and free from adhesions, except in the pelvis, where the small intestines were attached to the uterus on the right side, while the upper part of the sigmoid flexure had been drawn down into the pelvis and become adherent to the uterus. Perforation had occurred, allowing the escape of fæces. The ovaries were small, but not diseased.

*Rupture of the Uterus.*—Dr. JOHN WILLIAMS showed a specimen of rupture of the uterus, the rent being situated in the anterior aspect of the cervix. The patient in whom it occurred was under the care of Mr. Marshall of Colney Hatch Asylum, and, when first called to the case, Dr. Williams found her with extensive emphysema of the head and face, and of the whole trunk. The child was presenting by the breech, and he delivered without difficulty. The placenta was slightly adherent, and on separating it he felt a rupture in the cervix, apparently not implicating the peritoneum. At the *post mortem* examination, the cervix was found to be the seat of a rent of about an inch and a half in length, surrounded by a sacculated pouch; the broad ligament in its neighbourhood was excessively distended with air.—Mr. MARSHALL gave a history of the case previously to its being seen by Dr. John Williams.—The PRESIDENT suggested that the uterus should be submitted to microscopical examination. Many cases of so-called spontaneous rupture of the uterus had been recorded, but information was still wanted as to the histological characters of the organ in such cases.—Dr. BRAXTON HICKS considered that rupture of the uterus seldom, if ever, occurred now-a-days from excessive and violent action, as described in the text-books. Probably such an accident had been eliminated by our improved methods of delivery.

*Two Cases of Repair of the Female Bladder and Urethra* formed the subject of a paper by Mr. LAWSON TAIT of Birmingham. The first patient, S. H., aged 21, came under Mr. Tait's care on April 30th, 1877, two months after delivery. Ever since labour, her urine had dribbled away. On examination, the vestibulum vaginae was found to be merely a mass of cicatricial tissue, of almost cartilaginous hardness, and this extended up the posterior wall of the vagina for nearly two inches, and embraced the lateral walls of the passage for about half an inch further. On the anterior aspect, everything seemed gone, save the apex of the urethra, of which about three-eighths of an inch were left. At the roof of the vagina, a hard thick ridge ran across from side to side, and on the posterior surface of this the os uteri was discovered. In front of this ridge was a protrusion of mucous membrane, which was identified as the remains of the bladder, by the fact that the two ureters were discovered upon it. The anterior edge of this protrusion was adherent to the rim of the os pubis, and the whole of the mucous area was not much larger than a five-shilling piece. No trace of the anterior wall of the bladder could be found on careful search. Such being the state of things, Mr. Tait conceived that, if he could make anything in the shape of a tube out of the cicatricial tissue in the vaginal wall, he might, by releasing the ridge at each side, bring it and the uterus down, and, folding the remains of the bladder upon itself and fastening it to the new tube, might at least make a receptacle for a small quantity of urine. Accordingly, on May 15th, he made two flaps, each about an inch long, out of the tissue behind the symphysis pubis, and joined them in the middle by silver sutures. He did not attempt even to look at them again till July 14th, when he found the operation had practically failed. He, therefore, on July 18th, proceeded to make two similar but larger flaps, consisting of everything he could raise from the bone, and again united them in the middle. On examining the parts two months later, he found that a canal, three-quarters of an inch in length, and allowing the passage of a No. 6 catheter, had been formed. A few days later, he proceeded to make a raw surface on each side of this bridge at its upper end; he then made a deep incision at each end of the tense ridge at the upper part of the vagina, and, after arresting the hæmorrhage, pared the edge of the ridge and fastened it down to the raw surface with sutures, with the exception of one corner, where a free exit for the urine was left. On October 11th, he found that the whole of his proceedings had been successful, the artificial urethra leading into a bladder-cavity, and nothing remaining but to close the provisional orifice. This was done on November 17th, a cannula being kept in the urethra for twenty-four hours. The patient left the hospital on November 28th, unable to retain her urine, but returned on January 1st, when it was found that the urine escaped through one of the stitch-holes. A few days after this was healed, she began to have a sense of desire to pass urine, and was able to remain dry for about an hour. Since then, the quantity retained had increased from half an ounce to four ounces, and she described the feeling as being that almost of a

new life. In commenting on the reappearance of sphincter action after utter destruction of the sphincter muscle, Mr. Tait put forward two explanations: first, that some of the involuntary muscular fibres of the vaginal submucous tissue had taken on the action of a sphincter; and secondly, that a valve-shaped opening had been made, which only yielded on pressure being exerted upon it by the contraction of the muscular tissue in the remainder of the bladder when overdistended. The second case was that of Mrs. M. H., who since her last confinement, in January 1862, had been subjected to a variety of surgical proceedings for a "tear in the bladder", but without avail. In March 1877, Mr. Tait found a large irregular opening, extending from within an inch of the cervix uteri to within a quarter of an inch of the meatus urinarius, admitting of the protrusion of the anterior wall of the bladder. This opening was narrow at its two extremities, but very wide at the point where the trigone and neck of the bladder should have been, and thus tissue was lost just where it was most wanted. On March 17th, Mr. Tait operated upon the narrow part of the opening above, and lifted two urethral flaps with the view of forming the basis of a new urethra. The second part of the operation failed; it was, however, repeated with perfect success on April 6th. On May 16th, he operated on the remainder of the aperture by making two large wedge-shaped flaps, the axis of which coincided with the circumference of the vagina. The free truncated ends coincided with the margins of the fistula, and the lateral margins of each flap were formed by somewhat divergent incisions, which traversed round quite one-fourth of the circumference of the vagina. The flaps were then carefully joined at their apices, and the lateral margins stitched down so as to ease the apices of as much strain as possible, a drainage-tube being fastened in at the outer end of the lower left-hand incision. Union took place, except in a small portion for which the same operation was repeated on a smaller scale. The stitches were removed a fortnight later; and in a few days, the patient began to pass small quantities of urine with voluntary effort. By February 7th, 1878, she was passing eight and nine ounces of urine regularly, and was as well and as comfortable as she ever was in her life. In accordance with the President's request, Mr. Lawson Tait then demonstrated on the black-board the steps of the operations, adding that he had seen the first patient only a few days ago, and had found the shrinkage of the parts very considerable. The length of the urethra was now not more than a quarter of an inch; but it still served to keep the patient dry. In reply to Dr. Aveling, he said that the drainage-tube used in the first operation was one of Chassaignac's coiled wires; and that in the three cases in which he had employed it, he had not been troubled with the deposit upon it of phosphatic concretions.—Dr. AVELING had found that the concretions might be prevented by injecting twice a day a weak solution of nitric acid.—Dr. CLEVELAND asked whether it was necessary to keep the sutures in for so long a time as in Mr. Tait's cases. Did not the adhesions become sufficiently strong in fourteen or twenty-one days to admit of their removal with perfect safety?—Mr. LAWSON TAIT had never seen sutures do much harm by remaining in for long periods; but on this point he would appeal to Dr. Marion Sims, who had had probably more experience on the subject than any English surgeon.—Dr. MARION SIMS said that where there was plenty of tissue left, the operation for vesico-vaginal fistula was so easy, that we scarcely thought of recording successful cases; but those of Mr. Lawson Tait fell in quite a different category, and might be looked upon as most exceptional. He had hitherto regarded those cases in which the neck of the bladder was destroyed as all but incurable; and only a fortnight ago, he had reported unfavourably on such a case. Mr. Lawson Tait had, however, now laid down and followed out a new principle of action, and had invented a procedure which had never been tried before. As to the phosphatic deposits which had been mentioned, he believed that they never occurred except where the surface was denuded of epithelium. They might easily be cured by injecting a solution of nitrate of silver. The sutures, he believed, need never remain in longer than eight or nine days; otherwise, they were apt to excite a degree of ulceration which made it necessary to remove them.—Mr. TAIT said, in reply to Dr. Heywood Smith, that he did not attach importance to any particular kind of needle, but he liked the tubular needle very much indeed. Those usually employed made far too large holes, but he had had a special instrument made for him in Paris. As a rule, however, he thought the best needle was that invented by the late Professor Simon of Heidelberg, who was by far the most successful operator in these cases, and from whose teaching he had first derived the feeling that no case ought to be regarded as entirely hopeless.

**Rupture of the Uterus.**—Dr. HICKINBOTHAM of Birmingham contributed the notes of the case of a patient aged 32, who, when in the ninth month of her sixth pregnancy, fell off a chair on September 16th, 1875, and profuse hæmorrhage immediately followed. On Dr. Hickin-

botham's arrival a few minutes after, she was blanched and pulseless, and the floor was covered with blood. The hæmorrhage came from an opening in the posterior aspect of the uterine wall, which easily admitted two fingers, and through which the edge of the placenta could be readily felt. The os was undilated, and at least one inch from, and anterior to, the wound. A soft sponge soaked in cold water was at once pushed tightly up to the uterus, and ether and brandy administered. The idea of transfusion had to be given up, the apparatus being found out of order. The patient slowly rallied; and on examination twelve hours after the accident, the wound was found gaping, but there was no hæmorrhage from it. Labour came on on the 18th, and the head of the child was found greatly stretching the wound. The os was therefore pulled backward, so as to divert the stress of the pain from the rupture. Delivery was safely completed, and the patient had gradually recovered, though still very exsanguine. From the condition of the placenta, it had evidently been compressed by the foetal head. In explanation of the position and causation of the wound, Dr. Hickinbotham added that the patient had probably fallen with her abdomen across some part of the chair, and that the pressure ruptured the uterus in that part which happened to be weakest, and which was, in this instance, a point opposite to where the injury was received.—Mr. EDWARD SKINNER of Sheffield also narrated a case of this accident, which occurred in a young woman, aged 23, who was suddenly taken ill on the evening of January 2nd, 1877, with pain in the abdomen. She rapidly became worse, and when seen by Mr. Skinner was pale and collapsed, with a cold clammy skin and imperceptible pulse. The os uteri was found closed, and there was no hæmorrhage. She died about two hours after. On *post mortem* examination, the pelvis was found to contain a very large clot, with a three months' fetus in it, and part of the membranes and placenta, the other portion being still in the uterus, and projecting from a rupture an inch and a half long in its posterior wall. The walls of the uterus in the neighbourhood of the rupture were about half the thickness of the other parts and soft. The patient had had one confinement previously, from which she had made a good recovery; and there was nothing in her history to point to anything but spontaneous rupture. The week previous to her death, she was in bed two days, complaining of pain in the abdomen, but was not seen by any medical man. This was believed by Mr. Skinner to be really inflammation of the uterus, which led to the subsequent softening and thinning of the uterine walls.—Dr. BRANTON HICKS said that the case reminded him of one of intramural pregnancy, in which the fetus was expelled *per vaginam*, but the placenta was retained, and the patient died from internal hæmorrhage. A rupture had taken place through the peritoneal surface at the situation of a large sinus.—Mr. LAWSON TAIT mentioned a case of hæmorrhage into the peritoneal cavity, now under his care, which he believed to be due to rupture of the uterus. He had twice drawn off the effused blood by tapping, but it had again accumulated, and the condition of the patient was so severe that he proposed, in a day or two, to open the abdomen, and endeavour to discover the source of the hæmorrhage.—Some remarks were also made by Dr. CLEMENT GODSON, Dr. SQUIRE, and Dr. MALINS of Birmingham.

**A Case of Puerperal Convulsions** was contributed by Dr. W. T. GREENE. The convulsions appeared to have been mitigated by the use of morphia suppositories, and disappeared on the fourth day after delivery, after which the patient made a rapid recovery.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, MAY 2ND, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

**Caries of Cervical Vertebra.**—Mr. EDMUND OWEN exhibited a little girl with caries, who had suffered from neuralgia of both sides of the head and neck, and who walked with the greatest care, crying if anyone attempted to touch her. There was no retropharyngeal abscess. He fixed on a Sayre's "jury-mast", and the pain ceased immediately; and the girl was now quite happy running about the ward.—Drs. CLEVELAND and BUZZARD asked some questions, to which Mr. OWEN replied.

**Blepharospasm ending in Recovery.**—Dr. BUZZARD related a case of this rather rare affection in a man aged 50. It commenced by the eyelids closing spasmodically every few seconds. He was in excellent health in other respects. When talking or eating, the spasm was worse. After trying various points by pressure, he found that pressure on the tragus of the ear of that side checked the spasm. There was no apparent deafness, but some loss of hearing could be detected by Galton's whistle. Some wax was discovered in the ear, and removed; after which the constant current was applied. The spasm ceased during

the time the current was applied; and the permanent condition was improved on each application. A blister was also applied behind the ear. The case got quite well. Irritation of the fifth nerve was a common cause of blepharospasm; or it might be due to local irritation in the head and face. In this case, the auriculo-temporal branch of the fifth nerve was involved.—Mr. POWER said temporary spasm might result from overwork and imperfect nutrition of the nerve-centres, when tonics did good. The condition when established was very intractable.—Mr. SEWILL spoke of a case of spasm of the masseter muscles cured by extraction of some teeth.—Mr. E. OWEN, Dr. JOHN WILLIAMS, Mr. CRIPPS LAWRENCE, Dr. NESBITT, and Mr. GEORGE FIELD spoke; after which Dr. BUZZARD replied, saying that no internal treatment was adopted. The removal of the wax was the chief factor, though the use of the galvanic current might aid in the cure.

*Epithelioma of the Rectum.*—Mr. E. OWEN spoke of a case in a woman aged 39, of ischio-rectal abscess, followed by fistulous drains and a discharge. The granulations assumed an epitheliomatous character, and were removed; but the case grew steadily worse, and she died. The kidneys were found extensively diseased. There was a history of syphilis.—The PRESIDENT, Drs. DOUGLAS POWELL, MACLEAN, BUZZARD, and Messrs. POWER and HEYCOCK spoke; and Mr. OWEN replied, saying there were a number of small cells scattered throughout the kidneys.

*Fibroid Tumours of the Uterus treated by Sclerotic Acid.*—Dr. JOHN WILLIAMS related two cases of uterine fibroid treated by sclerotic acid. This acid readily dissolves in water, and in so far differs from ergotin. A woman aged 34 had suffered from severe flooding for some time. A fibroid tumour was detected; and half-grain doses of this acid were injected under the skin of the abdomen twice a week. The flooding was much reduced, when the woman went into the country; and then it returned. When she came back to town and the acid was again injected, the flooding was checked as before. The tumour was reduced in size. Like results were attained in a similar case, including a decrease in the size of the tumour. The injection caused some little pain at the time, but that was all. It was followed in about half-an-hour by uterine pains.—Drs. MAJOR, BUZZARD, CLEVELAND, BANTOCK, and PERCY BOULTON spoke; and the PRESIDENT said that, where the tumours were peritoneal, ergot in any form did little good. The pressure of the muscular fibres of the uterus in the growth caused the reduction in bulk.—Dr. WILLIAMS replied to the various questions put to him; after which the meeting adjourned.

## MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, FEBRUARY 6TH, 1878.

WILLIAM SANDERS, M.D., President, in the Chair.

*Goutre.*—Mr. SPENCE showed a goitre, removed from a young girl aged 13. It was very large, and constricted by the omohyoid, sterno-hyoid, and sterno-thyroid muscles, so that it looked as if there were distinct tumours below the angles of the jaw. There was little hæmorrhage during the operation, and that only from superficial incisions. When the tumour was removed, the trachea was seen to be compressed so much that it looked as if tracheotomy would be necessary. The patient suddenly sank next morning, probably from œdema glottidis.—A sister of this patient, aged 9, had also a similar large tumour, which had benefited from blistering.

*Excision of the Tongue.*—Mr. SPENCE showed two specimens of excision of half the tongue. The tongue and tonsils in one case were large and swollen, but the disease seemed to be confined to the one side. He removed the diseased part with the knife and thermo-cantery. On dividing the jaw in the middle line previously to this, the disease was seen not to be confined entirely to the one half of the tongue, but to extend obliquely at the tip. In the other case, the disease was less extensive, and the mouth was not swollen. He removed the diseased part, two lines in front of the base, and did not divide the jaw and cheek.

*Disease of Shoulder-Joint.*—Mr. SPENCE showed a specimen of disease of the shoulder-joint, of great interest pathologically. The case was that of a child aged 14, with a large abscess around the shoulder-joint, from disease in the surgical neck and tuberosities, extending down to the shaft. At a recent meeting, he had shown a specimen of caries of the neck of the femur. In this case, the incipient disease of the cartilage was seen to be spreading from the diseased state of the underlying bone.

*Removal of the Ulna.*—Mr. SPENCE showed a specimen of the greater part of the shaft of the ulna. A large abscess had formed, and irritative fever was present. He opened the abscess, and, finding the bone bare, stripped the periosteum off and removed it. The abscess, however, continued to discharge, and, as he found on examination that it commu-

nicated with the joint, he excised the upper part of the ulna. The result had been good, and it would be interesting to see how the humerus played on the upper part of the ulnar shaft.

*Cancer of Lip and Jaw.*—Mr. SPENCE showed a tumour removed for cancer of the lip affecting the jaw. Part of the jaw, masseter muscle, and the submaxillary gland were therefore removed.

*Examination of the Ear.*—Dr. KIRK DUNCANSON showed Weber-Liel's ear-magnifier and ear-microscope, as described in No. 10 of the *Monatsschrift für Ohrenheilkunde*, October 1870. After many failures, he had finally succeeded in having the instrument so constructed as to be of thoroughly practical benefit in the diagnosis and treatment of diseases of the ear. After having, by the usual means of examination, obtained a knowledge of the condition of the external ear-passage and drumhead, the structure, movements, etc., of the membrana tympani and the deeper structures of the ear could be minutely examined by the ear-microscope. With the ear-magnifier, as well as with the microscope, by exhausting the air in the cavity, or by forcing air into the cavity, the action of the membrana tympani under these coarser impressions could be seen. With the microscope, by previously having dusted the membrane with flour, the observer, by singing or speaking into the tube, could observe the separate particles, as it were, forming into lines, which enabled the vibrating capabilities of the various parts of the tympani to be measured by means of the micrometer in the eyepiece of the instrument. For example, it would be noticed how slight the movements of the outer segments of the drumhead were in comparison with those of the posterior segment. In certain pathological conditions of the membrane, it would be observed that the capability of excursion of the parts was not diminished, as was generally supposed, but was much increased.

*Diseases of the Kidney.*—Mr. D. T. HAMILTON showed microscopic preparations illustrative of diseases of the kidney, and, among others, that accompanying scarlet fever. In all the cases which he had examined, the change had been essentially that of an acute interstitial affection, characterised by the production of large dépôts of inflammatory cells between the convoluted tubules of the cortex, sometimes distributed diffusely, but much more frequently in and around the glomeruli themselves. The lesion, which was most typical, corresponded to what has been described by Klebs as "glomerulo-nephritis". In one instance, the appearances, both to the naked eye and microscopically, were quite characteristic. The organs were taken from a child who had suffered from postscarlatinal dropsy, and died with uræmic symptoms. They were about twice the natural size; the capsule was non-adherent, and, on stripping it off, an extremely pale yellow mottled surface was left, with, here and there, congested venous radicles. On cutting into the organ, the cortex was found to be enormously enlarged, of a pale yellow colour, and had a mottled appearance very much like, at first sight, the mottling seen in parenchymatous nephritis. On closer inspection, however, the pale spots producing the mottling were seen to be rounded, and corresponded to the situation of the Malpighian bodies. The microscopic examination confirmed this opinion. The first thing that seemed to take place was a proliferation of the connective tissue nuclei within the Malpighian tuft, giving rise to great constriction of its blood-vessels. The Malpighian capsule then participated in the same process, becoming much thickened. Finally, for a short distance around the Malpighian body, there was very considerable inflammatory exudation of a similar nature, but limited to this neighbourhood. The epithelium in most of the convoluted tubules seemed comparatively normal. There was no blocking up of the tubules, and it was only here and there the epithelium appeared to be at all fatty. The lesion was entirely different from that met with in acute tubular nephritis, any alteration which might exist in the epithelium of the tubes being undoubtedly secondary to the much more evident and much further developed acute interstitial change. The medulla, further, was deeply congested, apparently from the obstruction to the circulation in the Malpighian tufts. The lesion seemed to be a very fatal one, and was usually accompanied by coma and convulsions. In other cases of scarlet fever which Mr. Hamilton had examined, the lesion was always markedly interstitial, affecting the cortex chiefly, and characterised by the deposition of inflammatory material between the convoluted tubules. In those cases where there was a tendency to resolution, it was apparently brought about by the inflammatory cells becoming fatty, instead of organising; they broke down after a time, and were absorbed. The other specimens were illustrative of different forms of Bright's disease, with more special reference to chronic interstitial nephritis, which, in all respects, was a truly inflammatory process, and similar in its different aspects to like affections in the liver and lung, although by no means necessarily accompanied by them. Preparations from a case of pyelo-nephritis were also exhibited, showing a complete infiltration of the organ, with putrefactive or-

ganisms of the micrococcus variety. The affection presented exactly the same features as a diphtheritic mucous membrane, and undoubtedly was dependent on the same cause, namely, the introduction of some septic material into an organ previously weakened by disease. The beginning of these cases was usually a catarrh of the whole genito-urinary tract, following the passage of the catheter. There could be little doubt that this latter was the means by which the septic virus was introduced. The subsequent course of the disease consisted in the formation of a diphtheritic surface in the bladder, ureters, and kidneys themselves. The introduction of the catheter into a healthy bladder had evidently no effect; it was specially where there had been an old standing cystitis that it was so extremely dangerous.

**Sanitary Association.**—Professor FLEEMING JENKIN read a paper on a Sanitary Association for the inspection of houses.—Dr. TAYLOR asked if this Association contemplated the inspection of dairies.—Mr. JENKIN thought this lay more in the province of medical men and chemists. The drainage and ventilation of dairies, however, would be inspected.—Dr. TAYLOR would not feel safe under the protection of this Association, unless dairies were inspected.—Dr. GRAINGER STEWART said that, so soon as he had heard of the formation of this Association, he had come to the conclusion that it would be a great boon. Along with others, he had seen only too often how defective the drainage arrangements in Edinburgh houses were. One house, situated in the best part of Edinburgh, was well known to be exceedingly unhealthy. On examination, it was found that, just as manufactories consumed their own smoke, so this house consumed its own sewage; for in the whole basement-storey there was an accumulation of filth. There was an excellent drain, but nothing in it, so that he got an Irish labourer to crawl through from one end to the other. It was then found that a grating had been fixed at one end to prevent the entrance of rats into the house. This became blocked, and, through the rat-holes, the sewage percolated into the basement. Then, again, in a school where there was typhoid fever, the drains were looked to and cesspools in front of and behind the house cleared. But, after some fatal cases, further examination was made and a huge cesspool found under the base of the house. Such cases showed how much inspection was needed. In the first house, the inmates thought they were delicate; in the second, they considered themselves well until the typhoid came. He had risen to say how useful he believed such an Association would be, and that he intended to become a member of and take an interest in it.—Dr. JAMES CARMICHAEL wished to say that he thought the proposal inapplicable in a large number of cases, viz., in the houses of the poorer classes. He hoped that Professor Jenkin's ingenuity would overcome this, and that soon such inspection as he advocated would be compulsory.—Dr. A. G. MILLER directed attention to two points. In the first place, while Professor Jenkin had admitted that doctors had very frequently detected defective drainage, he yet spoke as if they should now give up attention to such matters. He thought, however, that medical men should be associated with the engineer, and that the latter should submit his plans to him. In the second place, while he had no objection to the Association, he thought it should go further. Prevention was better than cure. The drainage in Edinburgh houses was simply disgraceful. He hoped the day would come when a builder, who willingly and knowingly used bad drains, would be put on trial for his life, or at least severely punished.—Dr. J. A. RUSSELL said that, as much building was going on now, the Association could do something at present to prevent a bad system of drainage being adopted. They could only tinker the old houses, but the drains in new ones could be rightly arranged without cost. The plan of having pipes so placed as to be available for inspection could be easily enforced. Quite recently, on looking at a new terrace being built, he noticed that the soil was so wet that he only hoped the builder himself would occupy the basement. In other cases, all sanitary laws were set at defiance. He had seen the Lord Provost, and suggested that certain sections of the English Acts might be adopted in the new Police Act. He received a letter, saying that some of them would, but that others were already in the Provisional order. They were of no use, however, as they were not enforced, and would not be until public opinion was educated to ask for them.—Dr. A. SIMPSON felt greatly indebted to Mr. Jenkin for his clear exposition of the objects and method of working of the Sanitary Association. Immediately after he had an opportunity of examining the constitution of the Association, he had sent in his name as a member. He was glad the subject had been gone into so fully and admirably, and that its importance had been recognised by so large a meeting. He could add many instances such as Dr. Grainger Stewart had already given. Indeed, they had all seen enough to make them grind their teeth at architect, clerk of works, or plumber who should thus sow the seeds of death. Probably all medical men shared the feeling expressed, that more could be done in the way of extending

compulsory inspection; yet the Sanitary Association deserved credit for taking the first steps towards its realisation. They would be glad to have the scope of the Association so extended. One effect would be that none would go into a new house without a previous inspection of its drainage arrangements. He thought it would be well if, by a vote of thanks, the Society stamped with its approval the views of Mr. Jenkin. They heartily wished the Association success, although its efficient working would shorten their visits and attendance on patients; for not only did defective drainage cause disease, but it also greatly aggravated it. He moved: "That the Society accord a cordial vote of thanks to Professor Fleeming Jenkin for his paper on the working of the Sanitary Association, and declare its strong sympathy with its objects."—Dr. BLAIR CUNYNGHAME thought that it would be a good thing if the Association exercised a supervision over work, such as plumbing, while it was being done.—Dr. CLOUSTON concurred with all who had already spoken as to the immense importance of the subject. He had been educated unfortunately in prehygienic times, when hygiene was sneered at, and the health of the scavengers of Paris brought forward in proof of the harmlessness of the absence of sanitary precautions. Twelve months after his appointment to a large asylum, he lost thirty patients. He did not at first think that there was anything wrong with the drainage, but he soon found out they were as bad as they could possibly be. An enormous amount of money was spent in putting matters right, with the result of abalishing disease. When appointed, after this, to another large asylum, built under the direction of two of the most distinguished Edinburgh architects, he found the place surrounded by a series of small cesspools, causing continually septic diarrhoea. Since this was put right, the health had greatly improved and the sick diminished by a half. He felt strongly that this inspection should be extended to public institutions. Some of these were as bad as they could possibly be. For inspection, they would pay according to their number of patients; but forty or fifty guineas was nothing to such institutions. He agreed with Dr. Cunynghame as to the absolute badness of plumbers' and architects' work. Almost the first step in the right direction would be to poison them all off. Of all professions, plumbers were the most uneducated and pigheaded that could be imagined. He seconded Dr. Simpson's motion.—Dr. BRYAN WALLER gave one or two instances of bad sanitation, which had come under his own observation.—Mr. SPENCE said that Dr. Clouston's remarks brought to his recollection an instance where the fault lay in over-engineering. In the part of the surgical hospital where he had charge some time ago, there was a system of ventilation by heated air, exhausting cylinders, etc. In three months, hospital gangrene appeared, and even scratches and healing stumps were affected by it. When, however, the patients were removed to a place well ventilated by doors and windows, they recovered in about a week. He did not like special arrangements, unless there was a head engineer inspecting. The system of ventilation he had spoken of had acted well in another institution; but, when inspected in his wards, an essential part was found not to be in working order, so that, unless the nurses had opened the windows, the patients would have been suffocated. He had accordingly returned to the old system, and never regretted it.—Dr. FOULIS, as a medical man, had made up his mind to join this Association for the two reasons, that efficient inspection was necessary to ensure that defects would be corrected for the present and prevented for the future. He had seen cases where two or three members of a family died in twenty-four hours, in spite of all that could be done by the medical attendant. Professional men, called in, said there was nothing wrong with the drainage; but, two weeks afterwards, half a ton of fluid filth was found under the kitchen floor. Efficient inspection would have prevented this. In another instance, these officers were called in to inspect a house where a bad smell was perceived. They said there was nothing wrong, but yet, it was afterwards found that the sewage from a water closet above was percolating between the walls of the room. All medical men should consider it their duty to bring before their patients the fact that a poison could be swallowed, although it was not smelt. Every one now-a-days was learning physiology, *i. e.*, the laws of health. Let them encourage this, as it would promote the subject of sanitary reform.—Dr. ARGYLL ROBERTSON concurred with those who had already spoken that the Association was ably devised to meet a crying evil. He wished to direct Mr. Jenkin's attention to the fact that, during the absences of people in the country, the water in the proposed trap would evaporate. He would like to know how this could be obviated.—Dr. PETER YOUNG approved highly of Professor Jenkin's project, but objected to a duty being thrust on private individuals which public ones should perform. In the case of public buildings, they could not get a certificate from the borough engineer that all was right. In this there was something wrong. Private associations, however, could not do what public ones should.—Professor JENKIN said that, in his reply, he would begin

at the end. Public inspection would not do, as it would be the compulsory public inspection of the internal fittings of a house. Then compulsory inspecting powers were often vexatious. Another objection, too, was that they exacted a minimum, so as not to be harassing. The private association, however, would recommend what was best, as it was not compulsory to adopt it. They would make arrangements to criticise drainage, etc., in progress in new houses. Dr. Argyll Robertson's remarks were important, and he did not know at present what could be done. A communication with the air could, however, be made. He cordially agreed with all Mr. Spence said. They would be ready to inspect plumbers' work, and any plans submitted to them; but to recommend any special men would be invidious. They would be only too glad to inspect public buildings, at appropriate charges, in proportion to size, etc. They had no desire to exclude medical men from their plans. Nothing would help their Association so much as the co-operation of the medical profession. In the last place, there were undoubtedly many who were too poor to pay a guinea, and yet too rich to ask alms. They might have a lower rate for such, or the plan of co-operation might succeed.—The vote of thanks was carried unanimously.—In conveying the vote of thanks to Professor Jenkin, the PRESIDENT pointed out how closely the matter was connected with medical men. They had fought the battle of sanitary reform single-handed, with neither engineers nor the public on their side. He further supported the Sanitary Association because it did not proceed on a one portal system, letting loose a flood of half educated men on the country, but cultivated the best men and gave them the best opportunities for study. If the Association did good, and if its work were good, then all classes would join it; for even the poorest would make almost any sacrifice to secure the health of their family. The debate had been a most interesting one.—Professor FLEMING JENKIN thanked the members for their cordial vote of thanks, and expressed his deep sense of the great importance of the efforts medical men had made in the matter of sanitary reform. He had no wish to exclude them now, but would always be glad of their advice, whether they knew much about such matters or were ignorant of them. Engineers were now coming to the assistance of medical men, and he hoped their co-operation would be effectual.

#### GLASGOW MEDICO-CHIRURGICAL SOCIETY.

APRIL 5TH, 1878.

ALEXANDER PATTERSON, M.D., in the Chair.

*Pott's Disease of the Spine.*—Dr. G. H. B. MACLEOD described the best method of examining a case of Pott's disease of the spine, and demonstrated on a patient the application of Sayre's method of treating such a case. He had tried glue, starch, paraffin, and plaster of Paris, and preferred the latter as being cleaner and more easily handled. Dr. Macleod stated that the generally accepted view that spinal disease was due entirely to constitutional causes was not borne out by facts, as many cases had no history but that of a blow or fall having been sustained in a perfectly healthy patient.—Dr. MEWAN said he had tried the treatment in several cases with good result; but he preferred paraffin, which melted at 129 deg., as it was lighter than plaster of Paris.—Dr. MORTON thought that all the cases were connected more or less with a diathetic cause, and not entirely due to blows or falls.—Dr. PATTERSON agreed with Dr. Morton as to the cause being constitutional.

#### PATHOLOGICAL AND CLINICAL SOCIETY OF GLASGOW.

TUESDAY, JANUARY 8TH, 1878.

JOSEPH COATS, M.D., President, in the Chair.

*Acute Tuberculosis.*—Dr. GAIRDNER showed the parts from a case of acute tuberculosis. The lungs, kidneys, and liver were full of miliary tubercles; there was a small tubercular mass in the cerebellum; the ventricles of the brain were dilated with fluid, and the white substance softened; and the membranes of the brain were inflamed. The patient, W. H., aged 26, a boilermaker, was admitted into the Western Infirmary on December 30th, 1877. There was a great difficulty in obtaining facts as to the previous history, owing to his lethargic condition, but it appeared that his name had been inscribed upon the list for admission about a fortnight before as a case of phthisis. The apparently most urgent symptoms, however, were evidently those of cerebral oppression; and a suppression of urine absolutely, for three days after admission, raised a presumption that there might be a renal origin for the disease. On the other hand, the presumption of phthisis was corroborated by the physical signs in the chest, by the temperature, which

ranged from 100 deg. to 101.2 deg., and by the bodily conformation; but not all by the symptoms, there being almost no cough and no dyspnoea; respirations 26, pulse about 90. There was rather violent typhoid delirium at night, subsiding during the day; a dry brown tongue; no paralysis; no convulsions; the pupils acted to light, and were not either remarkably contracted or dilated. Frerichs's test for carbonate of ammonia in the breath gave inconclusive results. On the fourth day after admission, after a dose of compound jalap powder, followed by squill and spirit of nitrous ether, fourteen ounces of urine were procured by the catheter; specific gravity while warm 1030, very acid, no albumen, biliary reaction with nitric acid. On the next day, the coma was deeper, but still no convulsions and no paralysis, but occasional slight subsultus tendinum; temperature maximum, 102.8 deg.; pulse varying from 72 to 116; respirations a little over 20, perhaps with a very slight "cerebral" character of rhythm, but not very much; no cough, and an entire absence of respiratory oppression. From this to the death of the patient, on January 5th, 1878, there was scarcely any change, except deepening of the coma and increase of weakness. The evidence, however, derived from the statements of his wife during the last day of his life, tended to confirm the idea of positive cerebral disease as opposed to uræmic coma. She declared positively that, for six months at least, he had complained of frequent vomiting and headache, which symptoms were ascribed in the first instance to the bad air in which he worked, filled with the vapours of paraffin-lamps, etc. That the vomiting was a symptom of considerable importance, was made clear by her referring his emaciation to it chiefly, as she said he could never retain enough of food to nourish him; and, even when he was after a time laid up by a severe cold resulting in a cough and spit, the vomiting continued, and the headache appeared to be even increased by the cough, attracting attention in the form of a severe pain referred to the left temple. The breathing became difficult, and on several occasions mouthfuls of blood were spat up. His wife appeared not to have apprehended any positive cerebral mischief up to the moment of admission; and never at any time noticed any marked aberration of mind, nor yet squinting, deafness, loss of vision, or anything which presented itself as unusual or dangerous in respect of the brain. Her account of the family history was pretty distinct, and showed the death of the mother and one brother from chronic chest-disease; while a sister died in childhood; leaving only one brother, considerably younger than the patient, alive and healthy. The father was still alive, bed-ridden, and suffering evidently from pulmonary disease. Of her own children by the patient, four in number, three had died during infancy. The diagnosis in this case was correctly made; but it was interesting to observe how many of the conventional symptoms of tubercular meningitis, especially as it occurs at infantile ages, were absent. The presence of tubercle in the lungs was truly inferred from the physical signs present, but its amount and general diffusion were not suspected. The solitary ulcer found in the small intestine and the considerable amount of tubercle in the kidney and liver were also out of the range of diagnosis. Iodide of potassium was administered, but without any definite result.

*Early Fetus.*—Dr. HUGH MILLER showed a fetus at the sixth week of intra-uterine life. The mother was a multipara, and there were no special causes to bring on abortion. The membranes and parts of the fetus were in a complete state.

*Diphtheritic Exudation.*—Dr. JOSEPH COATS showed a diphtheritic exudation obtained from the throat of a patient of Dr. Cameron. The specimen had been kept in spirit before it was examined, but Dr. Coats had no difficulty in making out masses and swarms of micrococci in the exudation. These masses consisted of minute closely set granules. The granular masses of micrococci were found in the diphtheritic exudation and in the lymph-channels of the mucous membrane of the fauces. Recklinghausen had also found similar material in the kidneys; and others had seen them in the skin in erysipelas. It was inferred that the minute organism was the cause of the inflammatory condition in the throat in diphtheria.—Dr. DOUGALL inquired whether the micrococci had been found in the blood of the patients in diphtheria. It was just as likely that the micrococci were the result as the cause of the diphtheria.—Dr. A. ROBERTSON expressed a doubt as to whether these were really organisms, and, if so, whether they were related to the disease.—Dr. G. BUCHANAN asked if the micrococci were always present, or were merely accidental, in the exudation, which he had always looked on as an exudation in the ordinary course of asthenic inflammation.—Dr. KENFREW said he had seen such white diphtheritic coatings on excoriations in asthenic states (e.g., dropsy) on other mucous membranes than that of the throat.

*Pathology of the Lungs.*—Dr. JOSEPH COATS showed sections of the lung-tissue in hæmorrhagic infarct and in acute pneumonia. Cohnheim had said that in hæmorrhagic infarct there was a leakage of the cor-

pulses through the walls of the vessels, and consequently a filling of the air-cells with red corpuscles, but no fibrin. In pneumonia, on the other hand, there was fibrin with inflammatory cells in the alveoli. Dr. Coats's specimens bore out Cohnheim's views.

**Malposition of Teeth in Rabbits.**—Dr. DOUGALL showed two rabbit heads, in which from a slight displacement of the jaws, probably after injury, the upper and lower teeth had ceased to meet accurately, and the normal attrition had consequently been in abeyance. The teeth, however, had grown at the usual rate, and thus there was an enormous elongation of nearly all the teeth, more especially of the front ones. In a case recorded by Cuvier, the teeth had grown so long that one of the lower incisors had perforated the eye of the rabbit. Both of the rabbits from which the heads were taken were in good condition. The teeth, which were overgrown, formed a perfect curve.

## MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, APRIL 3RD, 1878.

FREDERICK A. HEATH, M.R.C.S., President, in the Chair.

**Restoration of Lower Jaw after Resection.**—Mr. BRADLEY showed a case of restoration of the lower jaw after excision. The left half of the inferior maxilla had been removed subperiosteally six weeks before for a myeloid tumour, and at the date of the meeting, bony reproduction of the part removed was almost complete.

**Amputation of the Thigh.**—Mr. BRADLEY showed a case of amputation of the thigh for alveolar sarcoma, in which there had been no return of the disease since the operation, twelve months before. Mr. Bradley advocated the use of long posterior skin-flaps and short anterior flaps, when it was elected to amputate the thigh by the flap method. He urged the superiority of this operation over the one now in vogue, on account of the great tendency of the posterior flap to retract, and stated that drainage might easily be effected from the sides of the wound or by buttonholing the hinder flap.

**Splint for Knee-Disease.**—Mr. BRADLEY exhibited a splint for diseases of the knee-joint. It consisted of a straight back-splint, with a foot-piece erected at an angle of 45 deg. This rotation outwards being the most comfortable position, and the one which the limb naturally assumed on lying flat on the back, was, therefore, that in which the most complete rest was obtained. He had employed it in the infirmary for the past six months with good results.

**Suture-Needle.**—Mr. BRADLEY exhibited a very ingenious needle, invented by a recent hospital patient, who had suffered greatly from the dragging of wire sutures through the edges of an incised wound. The wire passed from an eyelet at the side through the head of the needle; then a burr was put on the other end by means of a broad nibbed pair of tweezers; this allowed the passage of the wire through the side eyelet-hole, but not through the hole in the head, and thus the wire (necessarily less bulky than the needle) offered absolutely no resistance in its passage through the skin.

**Lamp for Mercurial Fumigation.**—Mr. BRADLEY exhibited an improved lamp for mercurial fumigation, which permitted, *inter alia*, of being extinguished by a small handle without moving the gauze covering.

**A Small Child.**—Mr. CULLINGWORTH mentioned the case of a remarkably small child which had been under his observation at St. Mary's Hospital. The mother had been delivered prematurely about the end of the seventh month. The child was brought to the hospital when it was four weeks old, on account of its "not thriving"; it then measured fourteen inches, and weighed exactly two pounds; it had a quantity of hair, and the forehead was covered with long down. There was an entire absence of subcutaneous fat, which gave the features the appearance of wrinkled age. The food consisted of sweetened milk and water given very frequently, a few drops at a time. The child lived to the age of six weeks; convulsions occurred during the last three days of life.

**Tumour of the Cerebellum.**—Dr. EMERYS JONES exhibited a cerebellar tumour, and related the history of the case. R. H., a lad aged 7, was admitted as a patient to the Eye Hospital, suffering from great headache, loss of vision, and unsteady gait, with a decided tendency to fall backwards. Ophthalmoscopic examination revealed double optic neuritis; the right optic nerve was quite atrophied. He died suddenly after a convulsive fit of an hour's duration. At the necropsy, the brain was found to be well developed. The veins were congested. There were about two pints of fluid. The right lobe of the cerebellum was quite replaced by a round well-defined tumour about the size of a hen's egg, which, on examination, was found to be a glioma.

**Palpebral Nevus.**—Dr. EMERYS JONES also exhibited a case of nevus of the palpebra in a child three months old. Its size was three

inches by one inch and three-quarters, occupying the whole of the upper lid. Several patches of the skin covering it were of a bright scarlet colour and naevoid; other patches in the interval were free and of the normal colour. It had been gradually increasing in size. The treatment adopted was electrolysis.

**Scarlatinal Endocarditis.**—Dr. HUMPHREYS exhibited some specimens of scarlatinal endocarditis. Out of seventeen inspections which he had made during the past fifteen months in cases of scarlet fever and its sequelæ, he had found evidence of endocarditis in four instances. The first was that of a boy aged 4, who died after two days' illness. Here two of the segments of the aortic valve were fused together; the mitral valve was healthy; the two layers of the pericardium were adherent. There was, however, a previous history of rheumatism. The second case was that of a boy aged 8, who died on the fourth day of illness. The aortic valves were reddened and swollen, and two of its segments had fused together. There was slight reddening and thickening of the edges of the mitral valves. The third case was that of a boy aged 8, who died on the fifth day. Here the anterior cusp of the mitral valve, with its attached chordæ tendinæ, was greatly swollen. The fourth was that of a girl aged 3, who died of nephritis six weeks after the onset of scarlet fever. The edges of the mitral valve were thickened and stained. The left ventricle was dilated, and contained an *ante mortem* clot at its apex. There was a recent infarction of the spleen.

**Syphilitic Liver.**—Dr. ROSS exhibited a liver from a boy aged 11, who was the subject of congenital syphilis. The organ contained half-a-dozen gummata, each being about the size of a walnut.

**Contributions to the Pathology of the Brain.**—Dr. ROSS showed the brain from a man who received an injury over the right eyebrow ten days before death. The bone was not fractured. The patient lay in a somnolent condition, but was not wholly unconscious, and there was no paralysis. Two days before death, the left facial muscles began to twitch; and some hours later spasmodic movements began in the left arm. Just before death, he had a severe general convulsion. An abscess about the size of a hen's egg was found in the prefrontal region of the right hemisphere. Dr. ROSS pointed out that, from the molar lesion in the frontal lobe, a molecular disturbance had extended, which affected, first, the posterior part of the second frontal convolutions (centre of facial muscles of opposite side), then the ascending frontal and parietal convolutions (centre of movements of opposite arm), and finally the disturbance had not merely affected the parietal lobule (centre of movements of opposite leg), but had also become diffused through the whole of the cortical motor area of both hemispheres, causing a severe general convulsion.—He also showed the brain from a man who had received a wound on the right side of the occiput with a sharp instrument, which had penetrated through the skull. The patient lived several weeks afterwards, and the scalp-wound had completely healed; but a small aperture was found in the skull. Some days before his death, he had a severe general convulsion; but the prominent symptom was delirium, especially at nights. There was some hyperæsthesia of the left side as a temporary symptom, but no other sensory disturbances. At the necropsy, evidences of meningitis were met with, particularly over the occipital and parietal lobes of both hemispheres; and to this the delirium and convulsions were probably to be attributed. In addition, an abscess, about the size of a hen's egg, was found in the substance of the right occipital lobe. The fibres radiating from the posterior third of the internal capsule were not completely interrupted; but a large number of them must have been destroyed. The absence of distinct sensory affections during life showed that the centripetal fibres passing to the cortex were not collected into distinct bundles like the centrifugal fibres, and that the sensory inlets to the cortex did not possess a definite localisation like the motor outlets.—He also exhibited the brain from a boy aged 4, whose case he brought under the notice of the Society two months ago. The diagnosis then was descending sclerosis of the right lateral column of the cord, and two tubercular tumours: one situated in the medullary substance immediately beneath the sulcus of Rolando of the left hemisphere; and the other in the left lobe of the cerebellum. At the necropsy, sclerosis of the right lateral column could be detected with the naked eye. Several tubercular tumours, each about the size of a hazelnut, were found in the left sulcus of Rolando; and another about the size of a pigeon's egg in the left lenticular nucleus, which had pressed inwards on the internal capsule, so as to have interrupted the motor tract. The right and middle lobes and a portion of the left lobe of the cerebellum were occupied by a tubercular mass.

**Removal of the Penis.**—Mr. STOCKS showed a man, whose penis he had removed in November last in a novel manner. The urethra was quite patent at the orifice, and he could pass urine with perfect ease. The operation was performed thus. A narrow-bladed knife was passed between the corpora cavernosa and the corpus spongiosum about an

inch behind the diseased part, and the former bodies were divided directly upwards. The knife was then placed in the bottom of the wound and carried directly forwards for about one-third of an inch, and then diagonally downwards and forwards forming an inferior flap. The urethra in this part was then freed from the corpus spongiosum, and loosened slightly from its attachments. The skin-flap was turned upwards, and a small slit or button-hole made in it, through which the loosened urethra was drawn by forceps and held until the skin-flap was adjusted and secured. The cut end of the urethra was then stitched to the edges of the button-hole. There was a redundancy of skin, but it formed an admirable artificial foreskin to protect the tender orifice of the urethra from injury, and formed no impediment to micturition when drawn back in the ordinary manner.

*Osteoid Cancer of the Arm.*—Mr. STOCKS showed a young man aged 25, from whose arm he had removed an osteoid cancer. The tumour, which weighed nearly four ounces and was almost lony to the touch, was situated in the triangular space between the pronators and supinators immediately below the elbow-joint. No attachment to the bone, though it had for, could be detected. He recovered favourably. The growth of the tumour had been exceedingly rapid. Seven weeks only had elapsed since he first noticed anything wrong. The circumference of the arm was three inches greater than that of the other. Dr. Drieschfeld had examined the tumour, which was of a rare and unusual type, microscopically, and reported that it consisted of an osseous matrix arranged in lamellæ which contained proper bone-corpuscles with lacunæ and canaliculi. In the intervals there was found a soft structure, in which were seen large multinuclear cells, large cells with one nucleus, and free nuclei, together with fine fibres and granular matter.

#### BRITISH MEDICAL ASSOCIATION.

##### BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

MARCH 14TH, 1878.

SAMPSON GANGLIE, F.R.S. Edin., President, in the Chair.

*Thymol.*—Mr. LAWSON TAIT showed specimens of thymol and thymolised lint and cotton-wool for the antiseptic treatment of wounds. He had employed them all in a number of operations during the last two months, rigidly carrying out antiseptic precautions, and he was much gratified at the results obtained.

*Ovariectomy.*—Dr. MALINS showed an ovarian cyst taken from a patient upon whom he had performed ovariectomy on February 26th. It weighed one pound nine ounces, and contained twenty-five pounds of fluid. The growth had been rapid, extending over twelve months only; the cyst had been tapped ten weeks previously. The patient had done well since the operation.

*Loose Cartilages in the Knee.*—Mr. H. G. LOWE exhibited two specimens of loose cartilages removed from the knee by Mr. Bartlett by opening the joint antiseptically. The first case was that of a man sixty-five years of age; the bodies had been noticed seven years. Four cartilages were removed. The second patient was a man aged 32; the bodies had been noticed sixteen years. Twenty-five cartilages were removed. Microscopic examination showed that the bodies consisted of hyaline and white fibrous cartilage, which had in parts undergone calcification; there was no true bone.

*Ostetric Tractors.*—Mr. MORGAN of Lichfield showed a pair of detached tractors applicable to any existing curved forceps, and intended to apply Tarnier's idea to them at a trifling cost, without adding to our stock of instruments one which is both cumbersome and costly. Each tractor was about twelve inches in length, with a ring at one end for the hand to pull by, and a short blunt hook at the uterine end, which hook fitted into the fenestra of the blades from without inwards. When these tractors were applied to the forceps, power was obtained of pulling in a new direction, namely, in that of the axis of the inlet of the pelvis. The tractors were bent slightly away from the forceps' blades at a point about three inches from the uterine end, so as not to press injuriously on the perineum.

*Ring for Fastening Maternity Forceps.*—Mr. MORGAN showed a strong India rubber ring about three times the size of those used on umbrellas, designed to supersede the use of clips or tapes for fastening together the handles of maternity forceps. The ring did not exercise injurious pressure on the child's head.

*Carbonised Cotton Wool.*—Mr. SAMPSON GANGLIE presented specimens of carbonised cotton-wool, prepared by Messrs. Robinson at the Wheat Bridge Mills, near Chesterfield. He pointed out the evils resulting from the use of cheap wadding and cotton-wool, which, being largely manufactured from cotton-waste, contains irritating mineral oil.

##### ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, MARCH 6TH, 1878.

FRANCIS OGSTON, M.D., President, in the Chair.

*Thrombosis of the Cerebral Sinuses.*—Dr. SMITH-SHAND reported a case of this disease. B. G., aged 46, married and having had nine children, was admitted into hospital complaining of severe pain in the head. She stated that she had been quite well up to six weeks before admission, but had then struck her forehead against a gas-bracket and received a small wound. She had had, a week after this, severe rigors, with a sharp shooting pain in the right eye and ear, and noises like bells in the head. She had never been free from pain since that time, and sometimes had had great exacerbations. The head-symptoms were somewhat relieved by profuse menstruation coming on about one week after the pain began, but returned on its cessation. She had not been able to leave her bed since the menses disappeared; and had suffered, in addition to the pain in the head, from vomiting, constipation, impaired sight and hearing on the right side, confusion of ideas, and slight delirium. She had never had any paralysis of motion or loss of general sensation. Two weeks before admission, she observed matter coming from the ear. On admission, a cicatrix was seen on the brow; purulent discharge issued from the right ear; there was a swelling behind and below that ear; and pain increased by pressure all over the scalp, and by percussion over the mastoid process. There were pain and difficulty in swallowing, and inability to open the mouth, except slightly. The tongue was moist and yellow; no appetite; bowels confined; skin dry and hot; temperature normal; pulse 88. She had great thirst; no vomiting. There was no history of previous disease. She was ordered iodide of potassium, and poultices to the neck and throat. On the seventh day after admission, having in the interval appeared slightly improved, she complained that the pain was much worse and that she could get little or no sleep. The right eye was more prominent than the left, and the pupil was dilated. The right tonsil was found to be pushed inwards and forwards. She was ordered a blister to the back of the neck. On the eleventh day, she was not improved; and had, in addition, pain on pressure over the thyroid cartilage, with feeling of suffocation. Seven days after this, she became delirious and unconscious, the delirium being low and muttering, and, after recovering consciousness for a short time, she passed into a state of coma, rolling her head from side to side on the pillow, and died two days afterwards comatose. At the *post mortem* examination, there was profuse discharge of fetid matter from the right ear, caused by an abscess in the neck bursting into the external auditory meatus. The abscess extended from the base of the skull to the root of the neck behind the clavicle; the carotid artery, with its coats slightly degenerated, lay to the inside of it, and the internal jugular vein lay loose in it. The coats of the vein were thin and sloughing, covered with small pale granulations. On laying it open, it was found to contain pus; it was closed above by a solid thrombus, and below its lower valves closed by their union. The solid thrombus above extended into the skull, along the right lateral sinus and the longitudinal sinus of the brain. Pus escaped from the abscess upwards into the cranial cavity, where the dura mater was torn from its attachment to the jugular foramen, but there was no escape before this. On removing the dura mater, a patch about the size of the palm of the hand of recent lymph, infiltrated with pus, was found covering the middle of the convex surface of the left hemisphere. There were no other adhesions of the dura mater to the brain. The brain weighed forty-four ounces; it was uniformly firm in texture, but otherwise healthy. It was covered with purulent lymph at the base over the pons Varolii, around the infundibulum of the pituitary body, and back part of the notch of the cerebellum. On the upper surface, the vessels of the pia mater were more or less abnormally injected with blood in patches. There was no subarachnoid effusion, nor any into the ventricles. The origins of the cranial nerves were not materially interfered with by the effusion. The right Casserian ganglion was softened and pulpy. There could be no doubt that the cause of the symptoms was the injury to the forehead; but the order of the formation of the thrombi was not clear. The part in which softening occurred was generally the oldest, and this would point to the jugular clot as having been first formed. Erysipelatous inflammation might have followed the injury to the brow, although there was no history of this, and purulent infiltration of the tissues of the neck, with consequent thrombosis of the internal jugular, afterwards extending backwards into the lateral and longitudinal sinuses; or, as a result of the injury, a small thrombic mass might have been carried by the facial into the internal jugular vein. More likely, however, from the symp-

toms, the progression of the thrombosis was by the ophthalmic vein to the cavernous and lateral sinuses.

*Case of Starvation.*—Dr. COWAN began by remarking that the case was not in itself very remarkable, but was brought before the Branch more on account of the exceptional circumstances attending it. The patient was picked up in mid-ocean, in an attempt to escape from the French naval service. On being picked up, he was found to be about twenty-eight years old, well built, and of average size. On being placed on a cot on the main-deck, it was observed that his eyes were much sunken, very glassy, with a peculiarly anxious or even suspiciously apprehensive look, giving the impression that he was a lunatic. The eyelids were red, as if from weeping, or this might have been from the action of the salt-water on them directly, or from its evaporation. The tongue was intensely red, except a narrow white furred line running down its centre from tip to root, and the edges alone were moist. The teeth were covered with a darkish coating resembling slime. The skin was dry and hard, giving off a smell like a bundle of clothes which had been opened after having been saturated with salt-water and was in process of drying. There did not appear to be very great emaciation, but he was unable to stand. Over the matrix of each nail, both on the fingers and toes, there was a small phlegmonous abscess, and, where these had burst, there was a discharge of a small quantity of very thin ichorous pus. The heart's action, as he lay quiet, was tolerably good, the pulsation being 66; but, on speaking or exerting himself in any way, there was a marked increase. The history was as follows. Along with another deserter, the patient left his ship in the post-captain's boat, for an island to which the trade-wind might have been expected certainly to have carried them safely in twenty-four hours. After clearing the land, one of the oars broke, and they having no sail, and the wind having shifted, the boat missed the island and drifted till picked up in mid-ocean. The voyage began on September 15th, and the man was picked up on October 8th. They had in the boat three cakes of chocolate, weighing altogether six ounces, which were expended on the third day. There were neither spirits nor wine, but there was a small quantity of tobacco, which, however, was not of much use, as lights failed. Much rain fell during the latter part of the voyage, and there was a considerable quantity found in the boat. After nine days, the other man threw himself into the sea. This was the account given by the survivor; but it was a matter of doubt as to whether he had not prolonged his own life by an act of cannibalism. The treatment pursued was sponging the body with soap and hot-water, and then giving small quantities of arrowroot or sago, with beef-tea or extractum carnis in which was a little sherry or brandy. He was fed every two hours. On the second day, he had boiled-fowl with rice, with beef-tea, and tea and bread. After he had been on board thirty-six hours, his bowels were moved, the evacuations being of a light colour and mostly watery. Very little urine was passed, and no thirst was complained of. On the third day, he had, in addition to his former diet, calves'-foot jelly, with a fair allowance of brandy. His pulse this day rose from 66 to 84. He was then transferred to the French authorities at Port France, and when last heard of, a few days afterwards, he was waiting his trial by court-martial for desertion.

##### SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

MARCH 21ST, 1878.

M. K. ROBINSON, M.D., in the Chair.

*Hydrophobia.*—Mr. CLEMENT WALTER reported a case of hydrophobia. The patient was a man aged 37, and he had been bitten twenty-four days before the symptoms came on. The usual remedies were tried without avail, and the case came to a rapid termination, the man dying thirty-six hours after his being seriously ill. One marked feature in this case was the excessive terror at any noise or approach, and the paroxysms were so violent that it was found impossible to use the subcutaneous injection, as any attempt to do so brought on extreme spasms.

*Diagnosis of Stone in the Bladder.*—Mr. TEEVAN read a paper on the importance of an early diagnosis of stone in the bladder.

*Foreign Body in the Female Bladder.*—Mr. WACHER showed a foreign body which he had removed from the bladder of a female. It consisted of a hair-pin, thickly encrusted with phosphate of lime, was of a whitish grey colour, and weighed three drachms and thirty-seven grains. The girl, aged 14, had been admitted into the Kent and Canterbury Hospital when the hair-pin was first passed into the bladder, but it could not then be found, and she was readmitted six months afterwards. There were symptoms of inflammation of the bladder,

thick ropy urine containing pus, pain in micturition, and, on admission, retention from the foreign body blocking the passage. Mr. Wacher dilated the urethra with one of Weiss's three-pronged instruments, and extracted the substance with a pair of dressing forceps. The girl had incontinence for six weeks, after which she perfectly recovered.

*Disruption of the Lower Epiphysis of the Tibia.*—Mr. W. H. COKE read a case in which a lad ten years of age, who was under his care at the Ashford Cottage Hospital, had, by jumping from a cart when in motion, sustained a compound displacement of the shaft of the tibia from its lower epiphysis. The bone protruded for an inch and a half on the inner side of the leg at a point corresponding with the junction of the epiphysis. The principal vessels were uninjured, and the tibia unbroken. Under chloroform, an attempt was made to reduce the fracture, but this could not be effected till half an inch had been removed from the lower end of the shaft. The case ultimately did well, and the boy had a very useful limb, without perceptible shortening, and with no impairment of the movements of the joint.

#### BRITISH MEDICAL ASSOCIATION.

##### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.

MARCH 29TH, 1878.

F. MANSEY, Esq., in the Chair.

*Diffused Melanotic Cancer originating in a Mole.*—Dr. FAIRLIE CLARKE read notes of a case of diffused melanotic cancer. The patient was a married woman. When she was forty-five years of age, a small black mole, which had existed all her life on the third toe of the left foot, began to enlarge and give pain. After a variety of milder measures had been tried during a period of two years, the mole was freely excised. A month later, two enlarged glands were removed from the left groin. They were both infiltrated with an inky material. These operations seemed to improve her state, and nothing was seen of her for five months. Then it was found that the whole left leg was redematous and speckled over with black spots—some large, some small. The adjacent skin also had an inky hue. From this time, the melanotic patches increased in number and extent, and it became apparent that the liver, and probably other viscera, were implicated in the disease. Four months later—or about two years and nine months from the date when the mole first began to enlarge—the patient died. It was found that the whole skin, subcutaneous tissues, and muscles of the left leg were black or speckled with melanotic tumours. The viscera of the thorax and abdomen were dotted in a similar manner. The liver and lungs were studded with large nodules, while the lymphatic glands were converted into black masses. The heart, the spleen, and the kidneys were apparently free from the disease. The head was not opened. The case was illustrated by two sketches, showing the appearance of the left thigh at different stages of the disease, and by a microscopic section.

*Relief of Dropsical Limbs.*—Dr. MILNER BARRY showed Dr. Southey's trocar and cannula, illustrating its use by the history of two cases of cardiac disease and dropsy. Dr. Barry also gave an interesting résumé of the means resorted to for relieving dropsical limbs, tracing them down from the earliest times to the present. Serration was used two thousand years ago by the Greeks, and then by the Romans and Arabians. The classical case of Dr. Samuel Johnson, thus relieved by Dr. Heberden and Mr. Cruikshank, was also mentioned. Incision was introduced by Dr. Meade a century ago; afterwards by Dr. Mason Good in 1825; and recommended by Dr. Todd thirty years since. Acupuncture was introduced, in 1823, by Dr. Churchill, advocated by Dr. Graves, and afterwards by Sir T. Watson. And lastly, the use of the trocar and cannula was first mentioned in a report of the Clinical Society, in 1871, by Dr. Hanfield Jones, and more immediately introduced by Dr. Southey in a paper read to the Clinical Society in April 1877.

*Membranous Dysmenorrhœa.*—Dr. RANKING read further notes of a case of membranous dysmenorrhœa, brought before the meeting last year. The case was much benefited by the application of Chapman's spinal hot bag to the lumbar region for two hours three times a day, and ten drops of Donovan's solution three times daily, taken orally, for three months. The general effects produced were: 1, diminution of suprapubic pain during the intervals; 2, shortening of the intermenstrual periods; 3, diminished formation and thickness of the membrane, it becoming less leathery and more distinctly cellular; 4, increased facility of separation of the membrane, and more rapid and complete expulsion; 5, shortening of the menstrual period from ten to four days; 6, more rapid recovery, in consequence of the diminution of pain and uterine action; 7, benefit indirectly accruing from dimi-

nished bruising of the cervical canal; S, smaller quantity of morphia required; 9, 10 iodism or mercurialisation.—Dr. HOLMAN strongly advised dilatation and incision of the os and cervix in such cases.

#### SURGICAL SOCIETY OF IRELAND.

FRIDAY, MARCH 15TH, 1878.

WILLIAM COLLES, M.D., F.R.C.S.I., in the Chair.

*Fracture of the Spine.*—Dr. WARREN read a paper on this subject, in which he related two cases of fracture of the spine, that had been treated in Stevens's Hospital. In both cases, the injury was the result of indirect violence, death occurring in twenty-four and thirty-four hours respectively. In the first case, the fracture took place at the seventh cervical vertebra; the paralysis of motion and sensation was complete, and the reflex excitability of the lower limbs was entirely lost. The temperature was 101 deg. Fahr. In this case, the *post mortem* examination showed that the spinal cord had been completely torn across and otherwise extensively lacerated. In the second case, the injury was higher up, viz., at the fifth cervical vertebra; paralysis of motion and sensation was not complete, and reflex movements could be excited in the lower extremities. Temperature 106 deg. Fahr. Here the necropsy revealed no laceration of the cord, but there was pressure on it from the displaced bone, and in the centre of the cord was a blood-clot. A comparison of these cases helped to confirm the observation that rupture of the spinal cord produced only a very slight rise in temperature; whilst continued irritation was productive of well marked thermal symptoms. In further confirmation of this, and as illustrative of how high the temperature might rise in spinal injuries, the writer related the remarkable case brought before the Clinical Society of London by Mr. Teale of Scarborough, in which the temperature rose to 122 deg. Fahr., and yet the patient recovered. (See BRITISH MEDICAL JOURNAL, March 6th, 1875.) Dr. Warren said he wished to draw the attention of the Society to a method of treating bed-sores, so distressing a feature in protracted spinal cases, which had not as yet received much attention in Dublin, i.e., by galvanism. This method, which was first brought before the profession by Dr. Crusel of St. Petersburg, had been attended with such surprising results in the hands of Hammond, Spencer Wells, and others, that it was, he thought, worthy of a more extended trial. The method of applying it was simple; a clean silver plate of a size corresponding to the ulcer was placed over the sore, a zinc plate, under which was placed a piece of chamois-leather wet in vinegar, having been laid on some part of the neighbouring healthy skin. The current was completed by a copper-wire joining the zinc and silver plates.

*Green Tea as an Antidote in Poisoning by Opium.*—Mr. TUFNELL read a paper on this subject, which had been forwarded to him by Dr. James Sewell, Professor in the University of Quebec. The case from which the author drew his conclusions was that of a lady who had been for some time under his care. At 11 P.M. one evening, he was hurriedly sent for; on arriving, he found her totally insensible, with pin-hole pupils, an imperceptible pulse, and, though almost incredible, only three respirations in two minutes, with all the other signs of opium-poisoning. He ascertained that, being in pain, she had taken three drachms of Battley's liquor opii sedativus every three hours till sleep was procured; altogether, he calculated she had taken three ounces and a half of Battley's solution. He immediately prepared a strong infusion of green tea, half-a-pint of which was injected up the rectum, where it was retained for half an-hour. This was repeated at intervals till 4 A.M., when she had so far recovered as to be able to speak; and at 8 A.M. she was pronounced out of danger; but, even then, her sight had not recovered, and she requested the gas to be lighted, though the sun was shining brightly into the room.—Dr. H. KENNEDY expressed his surprise at the rapidity of the cure, although no mention had been made of emetics, or the stomach-pump having been used. He thought there must be some error of observation or in the report of the case. Strong coffee, he said, had for a long time been a favourite antidote; and, as the active principle of tea and coffee was essentially the same, it seemed but reasonable to expect similar results; moreover, green tea had been used as a stimulant in fever by Drs. Percival, Grimshaw, and others in Dublin.—Dr. E. H. BENNETT thought that the thanks of the Society were due to Dr. Sewell for having brought this subject before them, though not a member. He agreed with Dr. Kennedy, that the facts as stated were very hard to credit.—Dr. BIGGAR, in seconding the vote of thanks, mentioned several cases of recovery under his care of or poisonous doses of laudanum.—The vote was then carried by acclamation.—Mr. TUFNELL said that Dr. Cameron, Professor of Chemistry in the College, had undertaken a series of experiments to test the antidotal effects of green tea in opium-poisoning.

*Epithelioma of the Lip, with Microscopic Sections illustrative of the various Stages of the Disease.*—Mr. RICHARDSON, in explaining the sections, directed special attention to the papillomatous projections so well marked in the older growths, and suggested the question as to whether these papillomatous projections were new formations, or only altered papillae.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, MARCH 9TH, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Horse-shoe Kidney.*—Dr. FINNY showed a specimen, from the body of a male subject in the dissecting-room, which illustrated the union or fusion together of the lower portion of both kidneys. The united portion of the kidneys lay on the abdominal aorta, about half-an-inch above its bifurcation. The inferior mesenteric artery, the spermatic vessels, and the ureters were in front of the horse-shoe. The renal arteries ran a normal course, but two arteries were connected with the kidneys inferiorly: one, on the right side, sprang from the aorta three-quarters of an inch above its bifurcation; the other, on the left side, took its origin from the left common iliac artery. The distribution of the venous system of the kidneys was normal. The hilum of each kidney was remarkably large.

*Cerebro-Spinal Meningitis.*—Dr. HAYDEN exhibited the brain and spinal cord of a man aged 24, intemperate, a plasterer by trade, who died after a few days' illness, of cerebro-spinal meningitis. It was the third fatal case of the disease he had seen within the past two months. There were large blotches on the skin, of a light purple tint. Coma, right hemiplegia, and proptosis were the final symptoms. After death, five or six ounces of serum escaped from the arachnoid cavity. The arachnoid itself was opaque and very vascular, but no effusion of lymph or pus was noticed. The cerebral ventricles contained clear serum, and the choroid plexuses were unusually vascular. The left middle cerebral lobe was softened. As regards the spinal cord, it was diffident in the middle of the dorsal region, and the membranes were hyperæmic.—Dr. NIXON regretted that the sympathetic system had not been particularly examined; and Dr. J. W. MOORE alluded to the coincidence of cerebro-spinal meningitis and small-pox.

*Amphoric Resonance in Solidification of Lung.*—Dr. NIXON presented the thoracic viscera of a man aged 56, who died of suppurative pneumonia. His tongue was extremely dry and brown, pulse rapid, temperature 102 deg. to 104.5 deg., and respirations 36 to 40. Physical signs of solidification of right lung were all present. At the base of this lung, amphoric resonance became developed; and ultimately there was pericardial friction. After death, section of the affected lung presented a marbled appearance. The upper lobe was friable and in a state of purulent infiltration. A portion of lung-tissue in the centre of the lower lobe was permeable to air, and this imprisoned air probably gave rise to the amphoric resonance. There was extensive recent pericarditis, with only a small pericardial effusion.

*Scrofulous Ulceration of Leg.*—Dr. E. H. BENNETT showed the left lower extremity of a man aged 25, which presented some striking pathological changes. Disease set in eight or ten years before, beginning at the toes, some of which were amputated to effect a cure. The limb became exceedingly deformed, the leg being bent across the body at right angles to the thigh. In consequence of this deformity, amputation was performed. The cartilages of the knee-joint had nearly disappeared from want of use. The leg was covered with superficial ulcerations, but there were no deep sinuses. The skin, fascia, and periosteum were all fused together into one rind. The muscles were converted into a peculiar fatty mass, and there was fatty degeneration even of portions of the tarsus, tibia, etc. None of the characters of the so-called lupoid ulceration were noted. The urine was that of amyloid degeneration of the kidneys.

SATURDAY, MARCH 16TH, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Effects of Chronic Osteitis in Scrofula.*—Dr. E. H. BENNETT exhibited sections of the limb shown at the previous meeting, and demonstrated that the primary disease had been osteitis of the bones of the leg, which was complicated by scrofulous ulceration of the integuments. The bones of the foot were entirely degenerated; their tissue was occupied or replaced by fat, while the joints of the tarsus and ankle were ankylosed from disuse. While the foot and lower segment of the leg exhibited the most extreme degeneration of the bones, the upper and middle segments of the leg bones were excessive in weight with the hardness and irregularity of chronic osteitis.

SATURDAY, MARCH 23RD, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Double Ureters.*—Mr. FRANK THORP PORTER exhibited a specimen of double ureters in a male subject aged about 30. The two ureters united into one trunk nearly an inch above the entrance into the bladder. The supernumerary ureter, surrounded by fat, came off at the upper part of the hilum of the kidney; while the other arose in the normal situation. The capsule of the kidney was loose. The ureter of the other kidney was quite normal. There was cirrhosis of the liver and chronic pneumonia in the same subject.—Dr. FINNY mentioned a case in which double ureters existed on both sides, all four vessels opening separately into the bladder.—Dr. BENNETT regarded double ureters as a common abnormality.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, APRIL 5TH, 1878.

T. CREED, M.D., in the Chair.

*Use of Mercury in Inflammations.*—Dr. J. C. THOROWGOOD read a paper on the use of mercury in certain inflammations. The object of the paper was to show with what success mercurial preparations might be employed against persistent bronchial inflammations, arising from cold, and occurring in persons of febrile temperament and average strength. In feeble and aged persons, mercury might be injurious. The author was of opinion that, while many years ago mercury was given far too freely, yet now practitioners were becoming unduly timid in its employment. Reference was made to a paper on the treatment of pleuritic effusions by the late Dr. Hope (in 1841), where thirty-five cases of pleuritic effusion consecutively were cured by the employment of mercury internally and by inunction. Dr. Thorowgood quoted cases of pleurisy and peritonitis very successfully treated by pilula hydrargyri cum scilla, and also by calomel and opium; he had never seen any injurious effect produced by this kind of treatment, and only once any sign of salivation. When absorption commenced, and the pulse and temperature fell, mercury should be discontinued as a rule.

## CORRESPONDENCE.

### THE MEDICAL DEFENCE ASSOCIATION AND THE NEW MEDICAL BILL.

SIR,—I shall feel obliged if you will permit me to inform your readers that the Duke of Richmond and Gordon, Lord President of the Privy Council, has kindly consented to receive a deputation from the Medical Defence Association on Monday next, in order that the members of the Association may have an opportunity of stating their views on the Bill to Amend the Medical Act of 1858 now before the House of Lords.

The Council of the Association having considered the Bill at several meetings, has adopted a memorial to be presented to the Lord President of the Privy Council, in which the chief points requiring further legislation are set forth. Briefly, these are as follows:

1. That a State Examining Board for each division of the kingdom be instituted, and that the examinations for the licence to practise be full and complete in medicine, surgery, and obstetrics.
2. That existing corporations retain the power to grant degrees and diplomas, but these should be regarded as honorary distinctions only.
3. That the General Medical Council have the power to register colonial practitioners, provided that they produce satisfactory evidence that they have passed an examination equal to that of the State Examining Board.
4. That no foreign practitioner be admitted to the *Medical Register*, or be allowed to practise in this country, unless he produces evidence that he is qualified to practise in his own country.
5. That the examinations for women should not be less stringent than those required to be passed by male candidates.
6. That the profession have direct representation on the General Medical Council.
7. That the public be efficiently protected against unqualified practitioners, and that the General Medical Council be required to prosecute those who falsely assume medical titles, or, being unregistered, practise medicine or surgery for gain.

The Council of the Association is of opinion that the above views fairly represent those of the general body of the profession. Should any registered practitioner, although not a member of the Association, wish to join the deputation, I am sure the President and Council will

gladly welcome him. The deputation will meet in the waiting-room at the Privy Council Office, Whitehall, on Monday next, at a quarter to three o'clock P.M.—I am, sir, your obedient servant,

GEORGE BROWN, Hon. Sec. Medical Defence Association.

12, Colebrooke Row, N., May 15th, 1878.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*HASTINGS.*—Mr. Ashenden reports the birth-rate in 1877 to have been 27.74 and the death-rate 16.08 per 1,000 population, and the infant mortality 11.5 per 100 births. The deaths from diarrhoea were more numerous in 1877 than in 1876, which is an exception to the rule elsewhere; but the total zymotic death-rate for Hastings and St. Leonards is small, viz., 1.1 per 1,000. There were 97 deaths from tubercular diseases, of which 42 were of visitors. The total number of deaths of visitors was 127, or rather above 20 per cent. of the whole number. The new filter-beds are said to "answer the purpose"; but the water contained more iron than usual. Analyses were made of eight well-waters, which were bad; and only nine articles of food were analysed, viz., six of mustard and three of milk. The sanatorium is open, and has been used for scarlatina cases; and the mortuary is finished. The report also contains a meteorological report by Mr. A. E. Murray.

*WATFORD.*—After stating the amount of sanitary work that he had done in 1877, Mr. Brett says that the Watford water "is the purest, most wholesome, and most palatable it is possible to have", although he admits that it is hard, being derived from the chalk. He discusses the question, Is hard water injurious to health? and concludes that it is not, "because lime is food—that is to say, necessary for life". He also says that fatal illness has been caused by the entrance of sewer-gas into houses, but does not give any instances. There were five deaths from small pox, one from scarlet fever, one from diphtheria, and one from typhus. The death-rate is returned at 15.7 per 1,000 calculated on the population of 1871, after excluding all the deaths in Leavesden Asylum, or, after allowing for increase of population, only 13.2 per 1,000.

*REDDITCH.*—Non-fatal cases of zymotic diseases constituted nearly one-third of the total number of cases of sickness reported to Mr. Page during the year. The birth-rate was 39.7, the death-rate 18.3, and the zymotic death-rate 2.1, per 1,000 population. There were 134 deaths under one year in each 100 births. Mr. Page gives a list of the localities specially inspected by him, in addition to the house-to-house inspection which he had carried out; as well as a list of the sanitary work performed by the inspector, which indicates a considerable amount of work for so small a place. A very large proportion of the houses are occupied by artisans and labourers; there are numerous public-houses, and comparatively few of the better class; so that the death-rate is lower than might have been expected. Besides a number of carefully compiled tables, there is a list of sanitary recommendations for the consideration of the local authority.

*STRET福德.*—The number of births registered in 1877 was 525, and of deaths 325, of which 38 were caused by scarlet fever, chiefly in the old part of the town, which is badly drained. One peculiar arrangement is noted; viz., the placing of "closets next to the scullery, with fireplaces in them". These are being made less noxious by frequent emptyings; but we should have thought that their removal to a distance from the houses, and re-erection without fireplaces, would have been far better. An inspection of all the old houses is being made, and many nuisances have been abated. Mr. Pottinger recommends the filling up of the cesspools, and "the introduction of a sanitary pan", which is to be emptied once a week. He also objects to the slaughter-houses, and proposes that an *abattoir* should be built in their place.

*RYDE.*—The birth-rate of this health resort is stated by Dr. Platt Wilks as having been 24.25, and the death-rate 15.2, per 1,000 inhabitants, or, excluding the deaths of non-residents, 14.5 per 1,000, in 1877. The infantile mortality was small; viz., 5 per cent. of the total births, and about 7½ per cent. of all the deaths. There were only 19 deaths from zymotic diseases. Although it has not been necessary

## OPERATION DAYS AT THE HOSPITALS.

- MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.
- TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.
- THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.
- FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.
- SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- TUESDAY.**—Pathological Society of London, 8.30 P.M. Mr. Nettleship: Carcinoma of the Orbit. Dr. Peacock: French Millstone-maker's Lung. Dr. P. Irvine: Cerebral Aneurysms. Dr. Cayley: Cerebral Embolism. Dr. T. Fox: Anatomy of Dysliprosis. Dr. K. Taylor: Cavity in the Spinal Cord. Mr. Spencer Watson: 1. Polypus from Nose, Antrum, and Orbit; 2. Colloid Cancer of Breast. Mr. Pearce Gould: Aneurysm of the Pulmonary Artery. Dr. Leared: Ovarian Cysts from Twin Infants. Mr. Adams: Spontaneous Rupture of the Oesophagus. Dr. Lanchester: Primary Cancer of Lung. Dr. Greenfield (for Dr. Saunders): Specimens of Biliary Cirrhosis. Dr. S. West: Aneurysm of Pulmonary Artery, with Fatal Hæmoptysis. Dr. Murchison (for Dr. Bancroft): Specimens of Filaria.
- FRIDAY.**—Clinical Society of London, 8.30 P.M. The President (for Dr. Day): "Sequel of Case of Chylous Discharge from Leg"; Dr. Farquharson: "Case of Quinine Rash"; Mr. Cripps: "Case of Gastrostomy for Intestinal Obstruction"; Dr. Murchison: "Incubative Period of Scarlet Fever, and of some other Diseases"; Mr. Bryant: "Sudden Death following Tapping of an Hydatid of the Liver"; Mr. Brown: "Sequel of a Case of Cancer of the Tongue".—Quekett Microscopical Club (University College, Gower Street), 8 P.M. Mr. B. Thompson Lowry: "On the Structure of the Eyes of Insects".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**BACCHUS.**—From the annual statement of the receipts and payments of St. Thomas's Hospital, it appears that £512 10s. 1d. was paid for porter, £425 12s. 6d. for wine, and £497 10s. 4d. for spirits, making a total of £1415 4s. 11d.

## UNQUALIFIED ASSISTANTS.

**SIR,**—I am afraid, from your remarks in the *JOURNAL* of this day, that you seem to have your vengeance wreaked on a hard struggling class—I mean "medical assistants *sine diploma*". After what has fallen from the Lord Mayor of Dublin and other people, I am afraid the poor unqualified medical assistant will not be able to hold up his head. I shall venture to state the position I hold, and then I venture to ask anybody whether I am not practically qualified. I matriculated at the London University in 1853, and served an apprenticeship to a physician of five years' duration. In the last year of my apprenticeship I had the dire misfortune to lose both my parents, one three months after the other; but, owing to the kind help of some relatives, I had money lent me to proceed with the hospital courses. I passed the first half of the M.B.C.M. Aberdeen, and now I am an assistant near the hospital. Little can you guess, sir, the hard struggling London life I have had. Although I am not fully qualified yet, still I will leave it to any practical man to say whether I am not able to prescribe and attend cases surgical, medical, or midwifery.

I heartily sympathise with the medical assistant, especially a man of no pecuniary means, and I hope and trust you will do the same.—I am, sir, your obedient servant,

London, May 4th, 1878.

UNDERGRADUATE.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

## MEDICAL REFORM AND THE CONJOINT SCHEME.

It certainly is rather startling to be told, and to have the assertion repeated in Parliament, that the British Medical Association wishes the scheme for a conjoint examining board to be made compulsory, when, on putting the question to himself, any member of the Association may find that, far from wishing it, he has the greatest objection to it. You will allow me, therefore, as a member of the Association, to protest against any such use of the collective term as is here made. The British Medical Association consists of all its members, and we know of no one of it which has a right to appropriate to itself the designation to the exclusion of any other section of the body; still less to represent certain opinions as those of the Association, when they are only the opinions of a portion of it. We trust that no member of the Association will permit himself to be carried away by the expression. Taking it at what it is worth, let him ask himself whether the opinion attributed to him be really his.

That the scheme in question is not wanted by the Medical Association, by the profession, or by the corporations, is amply proved by the fact that, though at any time during the last few years they had the option of joining such a conjoint board, they have not formed it; nay, they have resolutely opposed it; yet in the face of this we are gravely told that the British Medical Association rejects the Medical Act (1858) Amendment Bill "because it is permissive in respect of a conjoint scheme, and on another ground". Now, it is the scheme itself that is objected to. That it is permissive, is the only ground on which it is tolerated in the Bill at all; but the sooner it is removed from it the better. It is clear that its being permissive is only meant as a stepping-stone, from which, at some future time, it may be made compulsory. It is a plan, very common in politics, of trying what can be effected on the many by dint of repetition—an effort, in short, to get the profession sufficiently familiar with the idea to be able at last to force it on its members. It would appear, too, as if it emanated from the profession; and yet several years' acquaintance with it provokes the remark of Dr. W. T. Gardner of Glasgow, "the more we look at it the less we like it". When members of the profession repudiate it thus, it is to be hoped that we shall hear no more of its being the wish of the British Medical Association, which itself is still far from being the profession in Britain.

We object to the scheme of a conjoint board for the three kingdoms of Great Britain and Ireland, or for any of them separately, being, by Act of Parliament, made compulsory. There is no valid reason whatever that Parliament should interfere to place the direction or ordering of the medical education of the country in the hands of a few men, however eminent their names may deservedly be in the profession or with the public. The wider the basis of direction, the better for the practitioner and the public. Nor do we see any beauty in the so-called uniformity it is hoped would result from the adoption of the scheme; rather the reverse. A severe blow would be dealt at medical education by the endeavour to force it into one groove, which the scheme, if adopted, would in time certainly do; for all teaching in that case, to command the special success required under the scheme, would be directed, not to give a substantial knowledge of the subjects taught, but merely to pass its men, by lecturing in the manner most pleasing to the examining boards. It is well conceived in the interest of the "crammer", but in that of sound education it is difficult to imagine a worse. It would simply lead to a system of cramming, which is one of the inevitable results of that system of perpetual examinations now so much in vogue. Let any one consider whether this cultivates the intellect or encourages thinking. It is merely a strain on the memory, under which that latter too frequently breaks down.

As to the talk of competition downwards, we should like to see proof of this. It has been asserted that men have been admitted into the medical profession who do not use the English language correctly, and we are left to infer that their being so admitted has been a sort of bribe deliberately held out to them by certain schools unknown. Passing over the paltry nature of the bribe, we would only remark that that tendency has been in quite an opposite direction of late; but it would be interesting to have the examples of the incorrect use of the English language adduced, as well as the names of the schools at which the delinquents studied. It might be as well to know whether such an expression as "different to", which one so frequently finds, is among the examples objected to; and if the complainers would lay down some rule by which the hopeless confusion existing in the minds of some with reference to the verbs "to lay" and "to lie" might be obviated, it would be hailed as a boon, however small; meanwhile, it may be as well to remember that they who live in glass houses should not throw stones. There may be some slight inaccuracies passed over by examining boards, but those colleges by no means examine, nor could they, all the writings of the examined; nor is the proposed conjoint board likely to be faultless. There are many institutions in the country (the more the better if they can find room which hitherto have given a sound medical education, nor has it been shown that they have deteriorated lately; nay, there has been a laudable effort on the part of most of them to improve their teaching, and in this they have been very successful. Whence, then, the need of interference? One can surely acknowledge excellence in schools other than one's own; or are we to be so much the slaves of habit that we are to consider that alone right to which we ourselves are accustomed, and everything else necessarily wrong? That, truly, would show want of education as well as narrowness of mind. Yet it seems to be taken for granted that they are all bad, except one, and that is to be chosen as a model—not that it is the best, but simply that some few men in a certain locality in any of the three countries happen to know most about it, and little or nothing at all of the others, and that little seen through coloured spectacles, and to the usages of this model the medical education of the country is to be made to bend. Now, we say nothing against any one school, and we have a sincere admiration for many of the men at several without saying, but that restricted vision which can see good only in the school to which one has been accented, and is to be severely censured. Surely there is good in all, without it, none of them could have sprung up or continued, and each is most probably adapted better than any of the others to the circumstances of the country in which it is placed. That each has sprung up and grown to be what it is without any special fostering care from the state, is a proof of this. This spontaneous development is the healthiest state of existence, not only for medical but general education. It must be left uninterfered. The system that would force all minds to pass through an unvarying ordeal, both as to matter and manner, is to be condemned. That there are national differences of mind is too apparent to require proof. Develop what is worth developing in each, but do not stifle them by needless and injurious legislation.

The plea that the scheme is devised in the interests of the public is as worthless as it is indefinite. There are several different bodies in Britain whose licence to practise is fully recognised as valid on all hands, just because the education required by them in the candidates for their several diplomas is acknowledged to be sufficient, and is assuredly above what, vaguely designated as a minimum, might fairly be demanded under any new scheme whatever, under a conjoint board or otherwise. These licensing bodies are all known. It is as easy to verify their diplomas for registration under the present system, as it could be did they all emanate from any one licensing body. The protection to the public is absolutely the same. If the *Register* be inefficient now, there is nothing in the proposed scheme which will alter it. If we could get an Act of Parliament protecting the public against itself, which could be enforced, then we might have some chance of protecting the public. But the public does not want this protection; it deliberately, and with its eyes open in many instances, prefers the unqualified man, and that, too, in cases where fees are no object, and where consequently one might justly expect greater discrimination.

Neither is the scheme a good one if we look upon it from the point of view of the expense that would be entailed under it. Its immediate effect would be to increase the cost of medical education, already too great, by at least one-fourth—a result not in favour of the country; however it might be to the advantage of a few. This in itself is to be deprecated, since its tendency is to cut off from the medical profession some of the best thinking power this country or any other produces; for examinations must be paid for, and they must be held somewhere. Whether the student went to the examiner or the examiner to the student, the cost must be equally met by some one. Then, the inevitable "crammer" must be paid; and this institution of cramming would flourish under the scheme more than now, since to prevent himself being taken at a disadvantage, the strange student would put himself under the care of some kind guide to the examinations. Whether this is a desirable state of matters we do not stop to discuss. The fallacies of examinations generally have been pretty frequently exposed. Examinations should never be trusted to as the sole, or even as a principal, test of real education. A man getting up, by the aid alluded to above, a few of the pet hobbies of his examiners, is sure to stand high in them; but the frothy kind of display they call forth soon evaporates, and is no criterion of the education of the man.

Not to trespass further on your space, we should advise all men who care about the subject to read the capital letter of Dr. W. T. Gardner of Glasgow in your issue of the 20th April. If we mistake not, Dr. Gardner dislikes the centralising tendency of the scheme as much as we do, and he equally condemns the policy of needless interference with schools which have amply proved their capability of coping with any in the land.

R. S.  
Heckfield, Hants, April 25th, 1878.

#### WORKS IN THE ŒSOPHAGUS OF THE DOG.

SIR,—In reply to "Jo. C.," I believe there is no doubt that the filaria sanguinolenta is introduced by the mouth in food taken by the animal, and bores its way through the œsophagus. In one of the specimens exhibited at the Pathological Society some weeks since, two of these worms could be distinctly seen penetrating the œsophagus. With regard to the filaria Bancrofti (filaria ananalis hominis Lewisii), I do not think either alcohol, tobacco, or salt has any influence on them, because many of the Chinese partake freely of a strong spirit made from rice called "sam-shoo," and I think I may say all live extensively on salted provisions and smoke native tobacco, which is, though, of a very mild description. Some also are opium smokers. Small doses of turpentine taken internally by those affected with filaria seem to diminish their number.

I was somewhat disappointed the other evening at the Medical Society of London, on the reading of Dr. Manson's paper on filaria by Dr. Chubb, who very kindly came down for that purpose, at the little interest taken in the subject by the profession. Charge is oftened by the small attendance, and also at the premature closure of the discussion. This I state because it has already been demonstrated that filaria can be imported by any person possessing them in their blood, especially where the mosquito exists; and doubtless in this manner they were introduced into Australia, and probably they have been also in San Francisco, as to both these places large numbers of Chinese emigrate. We have many Chinese over here at the present time, and may yet have a much larger number. Some of them may possibly be the host of this parasite; and it is not impossible that either the fly or some other flying insect may act as intermediate host, or nurse, as Mr. Manson expresses it, instead of the mosquito, and thus we may yet have this terrible scourge inflicted on us.

I should like to know whether any of the profession in Japan have yet investigated this matter in chyluria, lematiria, elephantiasis, lymph scrothum, or any forms of lymphatic disease. Truly yours,

GEORGE CHAS. COLES.

April 1878.

#### ADVERTISEMENT FOR FELLOWS OF MEMBERS OF THE PROFESSION.

SIR,—The writer will be much obliged by an answer to the following. He attended, gratuitously, for many years the family of a married man who is long since dead, and which family was in affluent circumstances from hereditary property on both sides. The widow left two children—one a daughter, long since married to a benefited clergyman; the other a bachelor son, who need not have many wants on which to spend his means. No charge was ever made to the widow; but lately, after her death, I thought it not unfair to make a moderate charge for attendance during her last illness, and during the last year or so of her life. She leaving much property to be divided between two not necessitous children. The question is, was I entitled to find in a charge of about seven pounds, which I did, or should I have remained content for my services to be gratuitous as before? I should not omit to say that the widow was most liberal in showing her appreciation of the attendance required on past occasions.—I am, etc.,

R. G.

#### THE BRUSSELS DEGREE.

SIR,—A year or two ago "C. B. G." has been to Brussels getting his M.D. I have no doubt that many practitioners that have an eye upon the degree would feel obliged to him for the information that he offers through your columns. Visiting the notes of the questions asked at the examination for publication. There is a person residing in London who sends private circulars to individuals stating that he can procure the University to grant the degree on a modified examination. Is this possible? Should the Medical Acts Amendment Bill pass into law, can an M.D. Brussels of 1876 be registered (I mean when the holder's name is already in the *Register* in consequence of British qualifications)?—Yours, etc.,

May 1878.

1. I very much doubt whether any person has such an influence with the University as is mentioned by our correspondent. 2. The degree would be registrable if—as probably would be the case—the University were one of those recognised by the Medical Council.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the BRITISH MEDICAL JOURNAL, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than Thursday, Twelve o'clock.

#### FEES OF MEDICAL WITNESSES.

SIR,—I shall be obliged if you can help me with information as to the fees a medical witness is entitled to, as I have not found the practice to agree with that laid down in the diaries. I was subpoenaed to attend the March Assize in this city in the case of Regina v. Stevens—a case of malicious wounding—and was in attendance for several hours on Wednesday, the 20th, (the date fixed in the subpoena), Thursday, Friday, and Saturday. The trial eventually came off on Saturday, the 23rd. During this time I could get no information as to when I should be wanted. Since the trial, I am offered two guineas instead of four, as I expected. On writing to Mr. Bovill, the Clerk of Assize, to know why I am not paid a guinea a day, he replies that I am only entitled to two guineas—one for attendance before the grand jury, and one at the trial—and that there is no reason that he can see why I should have been allowed more, as I reside in the city, adding that the solicitor for the prosecution should have given me notice when I should be required. I shall be glad if you can tell me—1. Whether or not I am entitled, as stated in Lettis's *Medical Diary*, to one guinea a day for every day from the date of subpoena to the day of the trial. 2. What remedy I have in the present case, and how is it to be carried out. In London, as house-surgeon at Guy's, I have been paid a guinea a day in criminal cases from the commencement of assizes to the day of trial, although the case may not have occupied more than a couple of hours when called on.—Yours faithfully,

JAS. BANKART.

19, Southeyhay, Exeter, May 13th, 1878.

ENQUIRENS.—We do not think that, under the circumstances stated, our correspondent has any legal property in the prescription.

#### DEATH FROM CARBOLIC ACID POISONING.

SIR,—In your last issue, under the heading of "Death from Carbolic Acid," you allude to "a case that occurred in the Homerton Small-pox Hospital." Kindly allow me to say that this is an error; no such unfortunate event has ever taken place here.—Truly yours,

WM. GAYTON, Medical Superintendent.

The following communications have been handed to the General Manager:—Mr. J. Lewis, Birmingham; Dr. Charles Dyce, Edinburgh; Mr. Fredk. Eastwood, Huddersfield; General Banking Company; Mr. J. C. Sargeant, London; Mr. B. B. Joll, London.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Advertiser; The Daily Courier; The Kelso Chronicle; The Fifehire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. George Johnson, London; Dr. Alfred Carpenter, Croydon; Dr. J. G. McKendrick, Glasgow; Dr. E. Waters, Chester; Dr. Kingrose Atkins, Waterford; Dr. Bradbury, Cambridge; Mr. T. Spencer Wells, London; Dr. Joseph Bell, Edinburgh; Dr. Leslie Jones, Blackpool; Dr. R. J. Lee, London; Mr. A. Doran, London; Dr. W. H. Corfield, London; Dr. J. W. Moore, Dublin; Dr. J. N. Vinen, London; Mr. J. E. Ingpen, Putney; Dr. R. MacLaren, Carlisle; Dr. Lomlie Athill, Dublin; Mr. Richard Barwell, London; Mr. T. M. Stone, London; Dr. Harris, Worthing; Dr. J. Milner Fothergill, London; Our Paris Correspondent; Dr. Saundby, Birmingham; Dr. Grigg, London; Mr. F. R. Morgan, Morriston; The Secretary of the Royal College of Surgeons of Edinburgh; Mr. F. Page, Newcastle-upon-Tyne; Mr. Richard Davy, London; The Secretary of the Medical Society of London; Mr. J. B. Richards, Torquay; The Secretary of Apothecaries' Hall; Mr. C. F. Maunier, London; The Secretary of the Obstetrical Society; Mr. R. L. Bayley, Stourbridge; Mr. Coles, London; The Registrar-General of England; Mr. Ernest Carr Jackson, London; Mr. S. C. Smith, Halifax; The Registrar-General of Ireland; Mr. G. Eastes, London; Dr. Edis, London; The Secretary of the Quekett Microscopical Club; Dr. A. S. Taylor, London; Dr. Dudfield, London; Mr. G. Brown, London; Mr. Thomas Jones, Manchester; Dr. R. L. Batterbury, Birkhamstead; Inquirers; Mr. D. S. Bradley, Chesterfield; Mr. F. Eastwood, Huddersfield; Mr. John H. Insanity in Ancient and Modern Life; with Chapters on its Prevention. By Daniel Hack Tuke, M.D. London: Macmillan and Co. 1878.

## CLINICAL LECTURE

ON

## LATERAL CURVATURE OF THE SPINE.

*Delivered at University College Hospital.*

By CHRISTOPHER HEATH, F.R.C.S. Eng.,  
Holme Professor of Clinical Surgery in University College, London.

BEFORE bringing into the theatre a patient suffering from lateral curvature of the spine, I propose to say a few words on the disease and its causes, and to illustrate them on the back of a healthy young patient. In the first place, cases of lateral curvature of the spine are much more common in private than in hospital practice, and among the well-to-do rather than among the poorer classes. The complaint is much more frequent among females than males, for reasons which I will give presently; and especially common among young ladies from fourteen to twenty, whose dressmaker or dancing-mistress is the first to notice that one shoulder is "growing out". And yet we get cases from time to time in hospital practice, due either to old hip-disease, as in the patient coming here to-day, or from young persons carrying heavy weights habitually on one arm, as in errand-boys and nurse-girls.

I need hardly remind you, I hope, that the vertebral column is, owing to its construction, both elastic and flexible, and that it is maintained erect and at right angles to the pelvis by double sets of muscles, which in health exactly counterbalance one another. In this healthy girl whom I place before you, the legs are of the same length, the pelvis is consequently horizontal, and the spine vertical to it and straight. Now, I put a book beneath her right foot, and immediately the right side of the pelvis is correspondingly raised, and I make a little hollow in the right loin and curve the lumbar spine to the left. If that condition were maintained long enough, we should get a "compensating curve", as it is called, in the dorsal region (fig. 1)—i.e., the weight of the head and trunk being thrown a little out of the perpendicular, an involuntary effort is made to restore the equilibrium by throwing the shoulder to the opposite side; and you can easily understand that if this effort be perpetually going on, deformity will eventually result. The same thing occurs if I take away the book and get the girl to "stand at ease"—i.e., to throw her left foot forward with the knee bent, for you will see at once that the left side of the pelvis is lowered and the lumbar spine curved to that side. Nobody stands habitually at "attention" with both knees straight; but as we shift from one leg to the other every few minutes, we do our spines no harm. The same induced curvature of the lumbar spine can be shown if I make the girl sit down, and then raise one side of the seat more than the other.

You will see, now, how important it is in every case of spinal curvature to ascertain whether the pelvis is horizontal and the legs of the same length. This can be done readily enough, as in the patient before us, without any undue exposure of the person. But lateral curvature begins in another way, and in patients whose lower limbs are quite symmetrical. In weakly girls who have outgrown their strength, the muscles of the back are not strong enough to maintain the spine erect under the weight of the head and thorax, and the spine tends to assume curves both in the dorsal and the lumbar regions; for though we conventionally speak of "compensating" curves as if they followed one another, they are really produced together. Now, why should the dorsal curve be almost invariably to the right and the lumbar to the left, and not the converse? The reason is, no doubt, that the great majority of mankind are right-handed, and that the right limb, being more developed, is heavier, and the muscles which support it stronger, than on the left side. But, in addition to this, we must take into account the peculiar type of respiration in the female—that it is much more thoracic than

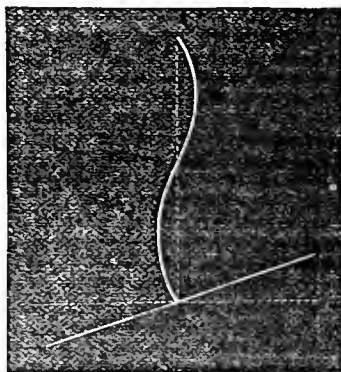

Fig 1.

in males, and particularly that the upper ribs move much more freely, the breasts of women rising and falling with each respiration in a way never seen in men. Now the important inspiratory muscle, the serratus magnus, takes its fixed point from the scapula and is inserted into the upper ribs, and must draw them upwards and backwards equally in health, but to one side more than the other, if from any cause the muscles are unequally developed, or if, as shown to you by Dr. Sayre last year, the pressure of the head and thorax upon a weakly supported spine tends directly to produce a rotation of the vertebrae. Undoubtedly the action of a non-counterbalanced serratus is to produce rotation of the vertebrae also, for the ribs act as long levers attached to their respective vertebrae, and hence one of the earliest changes in lateral curvature is a rotation of the vertebrae, so that the transverse processes on one side become unduly prominent by the sides of the spinous processes. Of course, the ribs, moving with the vertebrae, must be thrown back on the right side, and by their angles thrust out the scapula, thus causing the "out-growing shoulder"; and at the same

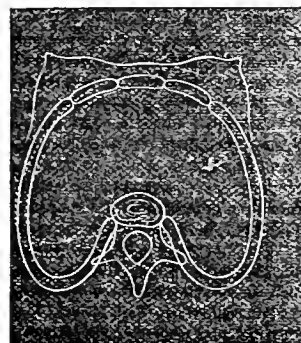

Fig. 2.

time, the left ribs being advanced, push forward the breast. Let me illustrate this by means of a diagram (fig. 2), and let me also warn you not to mistake a healthy breast thus thrust forward for one affected with disease, since you may be consulted for that symptom alone by a patient unaware of her deformity.

I will now dismiss the healthy subject, and bring in the patient suffering from actual curvature. This young woman, who is now aged 20, suffered from hip-disease on the left side at eight years old, and the result has been, as commonly happens, that the limb on that side has not kept pace with its fellow in growth; and as she stands now in slippers, you can see that the left side of the pelvis drops, and that there is a well marked lumbar curve to the left, with a so-called compensating curve of the ribs and dorsal spine to the right. Notice particularly how the right hip appears unduly prominent, and how the right scapula is thrust out. Now I will proceed to raise the left foot, so as to bring the pelvis straight, and you see at once a diminution in the lumbar curve, which of course cannot be rectified in a day; still less can the dorsal curve and rotation be put right without assistance, and that I propose to give by applying a plaster-of-Paris jacket after Sayre's method. Whilst the house-surgeon is making the necessary preparations for this, let me say a few words about other modes of treatment.

In cases where the curves are recent and slight and the patient young and flexible, a great deal can be done by employing the methods which I demonstrated at the beginning of this lecture on a healthy back with the view of producing curves for demonstration—only of course reversing the method. Thus with the ordinary form of curvature, where the dorsal curve is to the right and the lumbar to the left, it is obvious that we must raise the left side of the pelvis in order to straighten the back. Half an inch, gradually increased to an inch, added to the left boot will do a good deal, and the regular use of the sloping seat of Mr. Barwell one to two inches higher on the left side than the right, will do more to relieve the deformity, provided the muscles are not over-fatigued, and the patient has a pair of well-made stays to take off some of the weight of the trunk. Gymnastic exercises and calisthenics also are useful in strengthening the muscles, and particularly the action of climbing, which closely resembles the "self-suspension" recommended by Sayre, of which I shall speak directly, and which I have found to be an excellent method for cases not severe enough to require a plaster-of-Paris jacket.

In more severe cases, we have until recently had to rely upon some form of "spinal support"; and I show you here one or two specimens, only to warn you against employing them. I have tried them, both in hospital and private, and I must say I have never seen any good result; and I have watched the progress of cases in the hands of others more experienced than myself with as little benefit. The principle of all is the same: a steel pelvic-band with a crutch on each side is supposed to hold the trunk firmly, whilst a pad is worked by a lever with cog-wheels against the dorsal projection on one side and the lumbar curve on the other. Theoretically this is very satisfactory, for if with my two hands I grasp this patient on each side, you can see that I might in time push her back straight. But then you must remember that I am able to exercise a combination of complicated movements which no machinery can imitate, and that I occupy the enormous vantage ground

of standing apart from the patient, with my base of support on the floor. It is conceivable that if a spinal support could be made to be fixed in the ground and yet grasp the patient, it might effect some good; but as the modern machines are made to take the pelvis of the patient as their supposed fixed point, they are of no service, since they slip up and down as the screws are worked and as the patient's body moves. The proof of this is seen in one of the supports I show you, in which, in order if possible to counteract this "riding" tendency, an iron has been added, passing down the leg to a socket in the boot. Not only do these machines fail to do good, but they do positive harm by preventing the proper exercise of muscles; and yet they are extensively applied, and applied, too, to my certain knowledge, to cases where no apparatus at all could be required, the patient's back having nothing the matter with it!

And now we will suspend our patient, that you may see the effect of taking off the weight of the head and thorax, and of hanging the weight of the pelvis and lower limbs on the curved spine. Here we employ Sayre's triangle and slings; but for the patient's own use in exercising herself, I have had a much cheaper and less formidable set of pulleys made, which I have found to work well in private cases. It is simply a set of double pulleys, with a screw which can be fastened into the top of any ordinary bed room doorway or other convenient beam. It has the same head-piece as Sayre's, but no axillary straps or crossbar, which, indeed, are unnecessary for "self-suspension". A young lady can take this about with her when visiting friends without attracting attention, which could hardly be the case with a folding tripod.

We will now put on the knitted jersey with the "dinner-pad" over the abdomen and cotton-wool over the breasts, and apply the plaster-of-Paris bandage, strengthening it on the projecting side with strips of tin. While this is being done, I will give the mother of the patient directions as to the after-treatment which must be carried out. In the first place, we must raise the left side of the pelvis by adding half an inch to the heel of the left foot, which has already concealed in it a heel of three-quarters of an inch, which, however, is not sufficient. Next the patient must learn to exercise herself three times a day by adapting the head-sling and then, with the hands well over the head, suspending herself until only the toes touch the ground. While in this position, she is to take three deep breaths or inspirations slowly, and then lower herself again; and this, after a minute or two's rest, is to be repeated three times. In the intervals, she is to walk without fatiguing herself and to lie down for half an hour after each exercise. She has a comfortable home and is well fed, and, at present at least, requires no special medicine. In a fortnight's time, gentlemen, this patient will come before you again, and we shall then be able to judge of the amount of improvement which is likely to take place.

**CHRYSOPIANIC ACID OINTMENT IN PSORIASIS.**—Dr. Neumann of Vienna thus endorses (*Wiener Mediz. Presse*, No. 14-16, 1878) Mr. Balmanno Squire's treatment of psoriasis by an ointment of chrysophanic acid, as first communicated by Mr. Squire in this country at the latter end of 1876. After giving due credit to Mr. Squire, and to the other English observers who followed him in this research, the professor winds up his paper with the following summary. 1. Chrysophanic acid derived from Goa powder is an excellent remedy for herpes tonsurans, pityriasis versicolor, and psoriasis vulgaris. 2. Psoriasis in its earlier stages begins to disappear after a few applications of the drug, and in a far more unequivocal manner than under any other remedy that has ever yet been used against psoriasis. 3. Even inveterate forms of the disease can be abolished by means of chrysophanic acid, and it is quite the exception to find them oppose any protracted resistance to it. 4. Chrysophanic acid is a perfectly painless application to the diseased skin. The morbid phenomena occasioned by it on the healthy skin result apparently from the admixture of resinous matter with the acid. 5. As a result of this mode of treatment, psoriasis belongs no more to those skin diseases which in so high a degree are a source of misery to the patient, and it has now become an easy matter to cure relapses. Every patient with psoriasis that I have as yet treated by this means gives the palm without hesitation to this method of treatment in preference to all others. In any case, this at the least is emphatically true; namely, that the therapeutics of skin-diseases have for the last ten years been enriched by but few remedies which have been crowned by so eminent a success as the one in question. 6. There are other skin-diseases, also, which are curable by chrysophanic acid. 7. He expresses a hope that this method may be examined by other observers; and he does not doubt that it will soon permanently assume its due rank amongst the treasures of therapeutics.

## REMARKS

ON

### THE MINUTE ANATOMY OF THE SMALL RED GRANULAR KIDNEY.

By GEORGE JOHNSON, M.D., F.R.S.,

Professor of Clinical Medicine; Senior Physician to King's College Hospital; etc.

IN the March number of the *London Medical Record*, Dr. Saundby has given a clear and complete *résumé* of an able and interesting lecture by M. Charcot on what he designates "epithelial visceral cirrhoses". The lecture which Dr. Saundby has analysed is published in *Le Progrès Médical* of December 22nd, 1877, and February 2nd, 1878. M. Charcot's observations relate to the lung, the liver, and the kidney; and he shows that analogous changes occur in each of these organs. In his description of the structural changes in the small red kidney, he entirely confirms the account which I first gave of those changes in the thirtieth volume of the *Medico-Chirurgical Transactions*. Histologically, he says, there are two prominent facts: 1. The epithelium of the convoluted tubes undergoes granular degeneration, and finally disappears; 2. The connective tissue which surrounds and sustains the tubes is developed in excess. But he requests special attention to one particular: "At a given time, the dark granular epithelium which in the normal state lines the convoluted tubes is replaced by a cuboid epithelium resembling that of the collecting tubes." "This change", he says, "has been described by all histologists who have been engaged with the subject: George Johnson, Cornil, Ranvier, Kelsch, etc. It seems to be a fundamental characteristic of the small red kidney, and, if met with in other forms, is so only accidentally and in places."

After describing analogous changes in the lung and the liver, and stating that the changes found in these different organs are, (1) modifications of the granular epithelium, (2) modifications of the connective tissue-wall supporting this epithelium, he inquires which of these two is primary, and expresses his belief that it is the epithelial change; and therefore he calls the structural change "epithelial cirrhosis". Amongst other arguments in favour of this view, he says there is much reason to believe that epithelial tissues have an autonomous existence independent of subjacent structures, or at least without direct participation with the connective tissue in which they rest, except "for the supply of interstitial liquid: a necessary influence for the maintenance of vitality in all the tissues".

It is satisfactory to me to find that my views as to the relation of the epithelial and the interstitial changes which are found in the small red kidney are thus confirmed by so able an observer and so eminent a pathologist as M. Charcot.

In the lecture referred to, Charcot makes no reference to the state of the renal arterioles; but MM. Cornil and Ranvier, in their *Manuel d'Histologie Pathologique* (part 3), not only give the same description and illustration of the epithelial changes in the kidney, but they give drawings of the thickened arterioles which are identical with those which I first published in the thirty-third volume of the *Medico-Chirurgical Transactions*. This thickening of the arterial walls, however, they look upon as the result, not of a physiological hypertrophy, but of a chronic arteritis.

All the characteristic specimens of renal arterioles in the form of disease under consideration show an inner longitudinal and an outer circular layer of fibres of nearly equal thickness. I formerly supposed that the inner longitudinal as well as the outer circular layer was muscular; but I am now convinced that the inner is the thickened elastic coat; and, since this thickened inner layer in a hypertrophied renal arteriole has precisely the same structural appearance and arrangement as the elastic layer in the larger but still microscopic arteries, I cannot but look upon it as being thickened by a true hypertrophy or overgrowth of the normal tissue. And a probable explanation of this hypertrophy of the elastic inner tunic of the arterioles is to be found in the need for resisting the tendency to elongation of the arteries by the distending force of the hypertrophied left ventricle. The tortuosity of many of the hypertrophied renal arterioles shows that they have become more or less elongated by the injecting force of the heart, notwithstanding the increased thickness and strength of their longitudinal elastic tunic; and it can scarcely be doubted that, but for the

strengthening of the elastic coat by this hypertrophic thickening, the elongation and tortuosity of the arterioles would be much greater than they are. The tortuosity of the hypertrophied renal arterioles is well shown in my first illustration of this subject (*Med.-Chir. Trans.*, vol. xxxiii, p. 114), a copy of which is here given. (Figs. 1 and 2.)

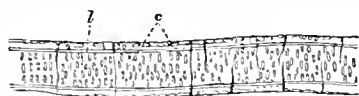

Fig. 1.—Portion of Renal Artery in the normal state, showing the relative thickness of its coats. *c.* Circular fibres. *l.* Longitudinal fibres. Magnified 200 diameters.

In a leading article in the *JOURNAL* of April 6th, reference is made to Dr. Ewald's paper in Virchow's *Archiv* on the Changes in the Arterioles in Bright's Disease. Dr. Ewald appears to have looked for hypertrophy of the arterioles in the pia mater alone, and therefore his

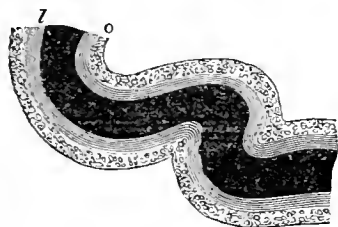

Fig. 2.—Portion of Artery from a Granular Kidney, showing great hypertrophy of its coats. *c.* Circular fibres. *l.* Longitudinal fibres. The canal of the vessel is filled with injection. Magnified 20 diameters.

observations are incomplete, and insufficient to support the objections which he raises to my explanation of the relationship between the arterial and the cardiac hypertrophy. In the cases in which he found hypertrophy of the heart without hypertrophy of the arterioles of the pia mater, it is probable that the arterioles in other tissues, more especially in the skin, may have been sufficiently hypertrophied to explain the cardiac hypertrophy; and, on the other hand, it is obvious that hypertrophy of the arterioles of the pia mater without arterial hypertrophy in other tissues would not cause cardiac hypertrophy. Therefore arterial hypertrophy limited to the pia mater may be unassociated with hypertrophy of the left ventricle. In reply to Ewald's argument, that "the absence of cardiac hypertrophy in amyloid and atheromatous thickening of the arterioles is against the vascular changes as causes of the heart-affection", I beg to say, as I have often said before, that, while this shows that mere degeneration of the walls of the arterioles, with consequent loss of contractile power, is not the cause of the hypertrophy of the heart, it is entirely in accord with the view that arterial contraction and resistance, with resulting arterial hypertrophy, are the main cause of the hypertrophy of the left ventricle associated with chronic renal disease. Ewald's theory, that the resistance which causes the arterial tension and the cardiac hypertrophy originates in the capillaries, and not in the contracting muscular arterioles, appears to me to be inconsistent with the facts and with the doctrines of vasomotor physiology. It is suggested that the polyuria of granular kidney is the result of increased pressure on the Malpighian capillaries consequent on capillary obstruction in front. To this I object, that increased pressure on the Malpighian capillaries would cause, not a copious secretion of urine, but an abundant transudation of albumen; whereas we find that, in cases of granular kidney with the evidence of high arterial resistance afforded by the great hypertrophy of the arterioles, albumen in the urine is rarely copious, usually scanty, and sometimes entirely absent. On the other hand, we have the clinical fact that when, as a result of valvular disease of the heart, the return of venous blood from the kidney is impeded, the increased pressure on the Malpighian capillaries is associated with a scanty secretion of highly concentrated urine, which, too, is often copiously albuminous. It appears, then, that the effect upon the urinary secretion of an impediment in front of the Malpighian capillaries is the exact opposite of that which the theory in question assumes it to be.

DR. MENZEL of Trieste, a surgeon who had already gained for himself a considerable reputation, has recently died at the early age of 32. While attending the Congress of German Surgeons in Berlin last month, he was attacked with hæmoptysis, and, after a brief illness, died of acute phthisis in the Augusta Hospital. He was one of the most eminent disciples of Billroth's school.

## CLINICAL LECTURE

ON

### ANTISEPTIC OSTEOTOMY FOR ANKYLOSIS AND DEFORMITY.

By RICHARD BARWELL, F.R.C.S.,  
Surgeon to Charing Cross Hospital.

[Concluded from page 707 of last number.]

GENTLEMEN,—A few words remain to be spoken concerning a different deformity, which I have kept for separate consideration, because of late some curative operations, with which I will contrast my own, have been introduced. The ordinary knock-knee, or *genu valgum*—a very common deformity—is always accompanied by obliquity of the femoral condyles, in such manner that the inner lies on a plane lower than the outer. I say accompanied by, and not, as is usually said, produced by, because I conclude from the great lateral looseness of the knee-joint that a certain yielding outwards of the tibia is likely to be the *primum mobile* of the deformity, and the faulty growth at the lower end of the femur, a secondary condition, superinduced by changes in the amount of pressure. I conceive, then, the malady not as a mere lengthening of the inner condyle, but as an obliquity of the whole lower epiphysis, caused by increased thickness of the entire epiphysal mass on the inner, or decreased thickness on the outer side. However this may be, it is certain that when the deformity is fully developed, the exaggerated projection downward of the internal condyle—in other words, the obliquity of the joint-surface—is the obstacle to rectification of the limb. The problem of surgery is to discover the best and safest method of overcoming or evading this obstacle.

Examination of the results obtained or not obtained by instrumental treatment, criticism of some earlier operations, such as cutting out a piece of the tibia, even sawing off the lower end of the femur, lie beside my purpose: I only wish to direct attention to the operations of Dr. Ogston (Aberdeen) and of Dr. Macewen (Glasgow). Dr. Ogston's method consists in passing a knife, then a saw, obliquely from above the inner condyle into the knee-joint, over the anterior surface of the femur, to midway between the two condyles: the inner one is then very nearly sawn off from before backward; the thin remaining portion of bone is broken by forcing the tibia into its normal position; and the condyle, thus pushed up on the femur, is allowed to attach itself in the new position (*Edinburgh Medical Journal*, 1877, p. 782; Langenbeck's *Archiv*, vol. xxi, p. 537). Dr. Macewen's method is thus described:—"An incision was made over the inner condyle of the right femur, the centre of which corresponded with the upper part of the condyle, the object being to go as near the knee-joint as possible without opening it. A V-shaped portion of bone was struck out by the chisel from the inner side of the condyloid extremity of the femur: the remainder of the bone was broken, and the limb was brought round straight."\* (*Lancet*, March 30th, 1878.)

Both these operations appear to me more severe than the exigencies demand. Of Dr. Macewen's, it is to be observed that two of the three cases suppurated, and under such circumstances there would seem to be some danger of extension of the inflammation to the knee-joint. From the description given in that gentleman's paper, and quoted above, it is difficult to make out in what direction the triangle of bone is struck out; but I suppose it to be horizontal. If I be correct in this supposition, the section would, I think, of necessity interfere with the epiphysal function, thereby in all probability affecting the subsequent growth of the limb.†

Dr. Ogston's operation is also rather severe—even, it would seem.

\* In his paper, Dr. Macewen claims to be the first in England who performed antiseptic osteotomy. I am not concerned here to dispute the assertion, which, although his case has only just been published, is doubtless correct. I would, however, point out that, in his osteotomy for ankylosis of the knee, he cut out a wedge of bone from the front of the femur. This procedure is not only different to mine, but is one that I deprecate as unnecessarily severe. Nature supplies a wedge of new bone to fill up an angular gap left between a deflected straight section with much greater precision than that with which a surgeon can cut out a piece to avoid a gap: the limb will not be shortened, and the bone will heal much more quickly and surely if a mere straight division be made.

† While the above was in press, I have received a note from Dr. Macewen, in which he informs me that the incision in the soft parts is vertical; the wedge-shaped piece of bone is oblique, sometimes horizontal.

hazardous.\* To pass a saw into the knee-joint, and then to partially fill that cavity with bone detritus, and the oozing from cancelli, is a procedure whose innocence could only be proved by a goodly array of thoroughly ascertained cases. It must also leave behind a femoral joint-surface greatly altered, and provided with a peculiar shelf and sharp prominence, with which the tibia cannot possibly fit; therefore one would like some after-history concerning the reliability and usefulness of the articulation. However, it is not my wish to criticise either of these very ingenious procedures, further than to show cause for the suggestion of a different operation, which, although performed in two stages, is less severe, and gives very excellent results. The following case sets forth the method I have adopted.

Kate L., aged 14, was admitted under my care into the Charing Cross Hospital on February 5th, 1878, in the hopes that a severe *genu valgum* of the left limb might be rectified. She is a healthy, but not strongly constituted, child. The plate gives a fair idea of the condition of limb. This child was for certain reasons not photographed. Her limb was laid on paper, and its outline carefully traced; also an iron wire was bent and moulded accurately to its outer side. From these tracings and moulds the plate has been drawn. I also procured a paper tracing from the healthy limb of a girl of equal age.

Fig. 5.

the tibia horizontally, just below the tubercle, and so deflected the lower part of the limb that the foot occupied the same place as that of a healthy limb, and applied the plaster-of-Paris bandage.

March 15th. There has been neither fever nor pain, and the wounds healed within the week.

**Results.**—The limb is now of very good form, and is strong; the knee-joint, not having been interfered with, is perfect (fig. 6). I was anxious, when I undertook the above operation, so to arrange that the limb should not merely look straight while the knee was extended, but that during flexion the tibia should move in its normal plane—that is to say, that in every posture of the limb, whether the median, turned out or in, flexion of the knee should always bring the heel in a circular line towards the tuber ischii: any deflexion outward or inward from this course would be a manifest result of error. This consideration caused me to take such pains, by the aid of tracings and mouldings, to divide the rectification of the deformity equally between the parts above and below the knee-joint. The result is perfect. The limb is shapely, not only while extended, but also in flexion; and in every position the heel, when the knee is quite bent, lies close to the tuberosity of the ischium.

There are now under my care two or three cases of exaggerated deformity—at hip, at knee, in the shafts of bone, which I show you as demanding treatment by this method; but I shall not for the present say more on this subject, having given ample grounds to justify the operation, and more especially having shown that the severer measures—the taking out wedges of bone—are quite unnecessary.

\* It is only right to say, that in a private letter Dr. Ogston tells me that he believes the operation has been performed about thirty times, and he is not aware of any ill effects having followed.

## CLINICAL COMMENTS

ON

### DYSIDROSIS AND ITS MORBID ANATOMY.

*Delivered at University College Hospital.*

By TILBURY FOX, M.D., F.R.C.P.,

Physician to the Department for Skin-Diseases.

GENTLEMEN,—For some years I have taught that there exists a special inflammatory disease of the skin, commencing in the sweat-apparatus, and characterised in its early stage anatomically by the development of little vesicles imbedded in the skin, which occupy the site, and are produced by the distension, of the sweat-ducts by fluid sweat rapidly becoming mixed with and altered by inflammatory fluid. This disease is usually confounded with acute eczema.

A typical case was admitted into the Hospital a fortnight ago, under my care, and exhibited the disease in both its earlier and later stages. I pointed out to you amongst other things the naked eye characters of the disease at its commencement; how the ridges of papillæ on the palms appeared to be redder and more distinct than usual, from the fact that they were in a state of tumefaction; how the sweat-follicles, or rather their orifices, appeared to be peculiarly distinct and recognisable; and how these follicles were apparently distended to form vesicles, which looked like little sago-grains imbedded in the skin. At least, these early vesicles were seen to be deeply seated and not produced by any elevation of the cuticle, and we thought we could make them out to occupy the site of the sweat-ducts, and trace transitional stages between increased distinctness of the follicular orifice and the formed vesicles. I explained also that the sweat-duct opening could be clearly made out in the centre of the imbedded vesicle.

I promised to try to obtain the patient's consent to the removal of a piece of skin for careful examination; and you will be glad to hear that I have succeeded. Some of you saw me mark between two ink lines a portion of skin containing a few ridges of papillæ, where I stated that characteristic vesicles existed in an early stage, *i.e.*, about the fourth day of the disease. The portion of skin was removed, and Dr. Crocker kindly took charge of it for the purpose of preparing some microscopical sections, which he has accordingly done with much success. Dr. Crocker and I have carefully examined these preparations, and I will now acquaint you briefly with the main results obtained. You shall examine, however, some of the preparations for yourselves.

It has been stated lately by several observers that dysidrosis is not a disease of the sweat-apparatus, and Dr. Robinson of New York especially, in a recent article in the *New York Journal of Dermatology*, professes to have proved that the vesicles are formed by distension of the rete mucosum by inflammatory fluid effused from the vessels of the papillæ; and he figures the vesicles seated over the papillæ.

Whether Dr. Robinson's case was a true instance of dysidrosis or not I cannot say, but our present case undoubtedly is; and what we find in our specimens is conclusive evidence that the sweat-ducts are very large and in some cases distended at their upper part, and that the vesicles are formed in connection with the sweat-ducts. Out of seventy or eighty specimens, we can only detect two instances of vesicles having any definite relation to the papillæ. The majority are distinctly formed *between* the papillary projections of the rete, their central axis being opposite to or a continuation of the depression in the rete answering to the usual spot where the sweat-coil enters the rete from above. In some cases, the duct, as it enters the rete, seems larger, as though commencing to dilate; but we can trace the sweat-ducts entering the little vesiculations or globular dilatations, sometimes at the central point of their summits, at other times more to the side, but still distinctly entering. We can see the sweat-ducts leaving the base of the vesiculations, in some cases at the central point. In some specimens, the duct projects slightly into the vesicles, and then its continuation is seen running from the direction of the bottom of the vesicle and continuing its course through the corium. There is one remarkable specimen of a twin vesicle with two contiguous sweat-ducts clearly entering the vesicles. In none is the horny layer of the cuticle raised into vesiculations at the early stage of the disease. We have searched in vain for the early phenomena of *eczematous* inflammation. In our sections, the sweat-ducts are everywhere unusually well seen: Dr. Robinson figures none. As to the changes that go on in the deeper portions of the sweat-gland, further investigation is needed; but I have

Fig. 6.

little hesitation in saying that I regard the appearances seen in some of the sections as indicative of commencing inflammation. The cell elements of the wall of the gland ducts and of the tissue of the gland-coil and its envelope seem augmented.

To my mind, the views I have taught in this School about dysidrosis are fully vindicated by these preparations. In my *Atlas*, published in 1877, I remarked that "if the skin be examined at an early stage with a lens, in many cases it will be seen that these little pearly spots answer exactly in situation to the sweat-ducts, and indeed they are distensions of the sweat-apparatus. This has been represented in fig. 3, which was the exact appearance seen in the case, and which was most plainly put by several others beside myself. This conclusively proves that the disease is essentially a disorder of the sweat-apparatus". As to the mechanism of the production of these vesicles, I wrote as follows, in 1873: "It seems to me that there is a sudden efflux of sweat, and the flow is so rapid that it cannot escape, the whole gland is distended, at least its duct, and the fluid presses up from below only to block up the upper portion of the duct by pressing together the twists of the duct in that part of the cutis where it runs in a spiral manner. If there be sudden pressure from below, the spiral twist of the duct must greatly favour the dilatation of the duct. In sudamina, I take it, the opening is plugged by exuvia, and the sweat finds its way laterally between the horny layers of the cuticle....." I think the basis of the above explanation holds good. Dr. Crocker and I propose to work out the anatomy of dysidrosis, as far as we can, more fully, and to place on record our joint observations on the matter. I thought it well, whilst the clinical features of our recent case were fresh in your minds, to show you these specimens, and thus vindicate the correctness of my teaching on the subject during the last few years.

[The above noted points were then fully demonstrated by the specimens.]

## DIPHTHERIA.

By ROBERT BELL, M.D., F.F.P.S. Glasgow,

Physician to the Glasgow Institution for Diseases of Women and Children, etc.

In January 1876, it was my privilege to publish in the JOURNAL a short account of the plan of treating diphtheria, which I have adopted during the past few years. It is now my desire to detail the history of other cases of the disease which have passed under my notice since that date. It will be remembered that, under the treatment which was advocated, all the patients recovered, with the exception of two, who proved themselves so obstinate that any attempt to carry out my wishes was frustrated. Since the publication of the paper referred to, I have met with at least eight well marked cases of this disease, all of which recovered. I am induced to give an account of my further experience of this mode of treatment for many reasons, chief amongst these being that my medical brethren, who were in communication with me on the subject after the appearance of my former paper, may have further proof to support them in their endeavours to combat the disease by the means which have proved so successful in my hands.

Cases I and II, M. F. and A. F., sister and brother, aged 10 years and 8 years respectively, were both prostrated on the same day. The film was spreading very rapidly over the tonsils, and there was considerable fever. The throat of each patient was freely painted every two hours with the following application: glycerine of carbolic acid, the strong liquor of the perchloride of iron, and sulphurous acid, of each three drachms; and the following mixture was given: chlorate of potash, two drachms; sulphurous acid, two and a half drachms; glycerine, one ounce; and water, to four ounces: two tea-spoonfuls to be taken every two hours. In this way, while the patients were awake, an antiseptic was brought into contact with the diseased surfaces every hour. Port wine, soups, and milk were also given freely. The tonsils had only been painted a few times when the film showed signs of ceasing to spread; and within four days all the diphtheritic membrane had disappeared, and, saving a considerable amount of prostration, the patients were pretty well. A course of tonic treatment, however, soon removed this debility.

Case III was confined to one member of the family, but the disease was epidemic at the time. The patient was a girl thirteen years of age. The treatment as described above was adopted, and the disease ran very much the same course as in the two first mentioned cases.

Case IV was the most intractable attack of diphtheria that I have seen. The patient was an only daughter, aged 16, and before her illness was a remarkably healthy looking girl. I saw her first on the 26th December last, and then considerable areas on both tonsils were covered with the fungoid deposit. The treatment was immediately

commenced, and most rigorously carried out; but in this instance, it seemed for some time to have no control over the disease, for the false membrane continued to spread, till on looking into the throat nothing could be seen but the diphtheritic deposit. The treatment, however, was persevered in most persistently. Unfortunately, when the disease was about its worst, I became so unwell that I could not leave my bed for a day, and a friend kindly took charge of the case for me, who saw that my instructions were most rigidly carried out. The father of the child, feeling desperate, asked to be permitted to see me in bed, to ascertain if nothing else could be done to relieve his daughter, my friend having looked upon the case as hopeless. I suggested a consultation, but the consultant said he could only confirm what my substitute had already said. Both, in fact, viewed the condition of the patient as being beyond hope of recovery. During all this time, be it remarked, the antiseptic application to the throat had the effect of preventing the poison from being absorbed into the general system, and on this account, I thought there were still reasonable grounds for hope. Having made the parents understand this, I urged them to persevere most conscientiously with the treatment, which they did; and with the assistance of my friend Dr. Brock, nothing was lost for want of a thorough application of the remedies. On January 3rd, the symptoms began to abate; and from that time, her recovery was uninterrupted.

Cases V and VI were brother and sister, the only children of the family. Their history is very similar to that of Cases I and II, and their recovery was quite as complete; though, in the girl, there still exists a great weakness of the throat, rendering her very prone to tonsillitis.

Cases VII and VIII are very recently recovered from an attack of diphtheria. They are now quite rid of the disease, but are still suffering from the resulting weakness. They are likewise brother and sister, four and six years of age. It may be interesting to note that the laundrymaid in this family had an attack of diphtheria about eighteen months ago, from which she recovered under similar treatment.

Since the above was written, another child of the same household has been attacked, but is now on a fair way to recovery.

I would remark that, in every house where the above cases occurred, the arrangements for supplying the inmates with water were defective. In every instance, the drinking-water was drawn from a cistern, which was placed above the water-closet and bath-room; and when the cisterns were examined, they were found to contain an immense accumulation of slimy matter of a green colour, which under the microscope proved to be loaded with minute organisms, the greater number of which were of the same form as blood-corpuscles, and about the  $\frac{1}{1000}$  of an inch in diameter. There can be little doubt that these microscopic bodies were the germs from which the disease sprang; and there can no estimate be formed of the immense amount of preventable zymotic disease which is constantly attacking the community under similar unsanitary conditions. It behoves us, then, as custodians of the public health, to insist that such unscientific, nay criminal, modes of constructing houses be prevented.

P.S.—The above paper was written in the autumn of last year, and within the period which has elapsed since then, twelve other cases of diphtheria have come under my observation, all of whom have recovered under the same treatment. I may mention that five out of this number occurred in one family. Again the cistern-water was at fault.

## EXCISION OF THE TONGUE BY IMMEDIATE LIGATION.

By WILLIAM FEARNLEY, L.R.C.S. Edin., Lerwick, Shetland.

THE publication of Mr. Lund's case of removal of the tongue by scissors induces me to publish the following case.

Christina J., of Tingwall parish, came into Lerwick to consult me regarding a sore on her tongue. She came to me on November 6th, 1875. She was then aged 66; was living with a sister older than herself; had a good family history; had enjoyed average health all her life; had never been married. I found a large "sore" on the right border of her tongue opposite to and touching the only tooth in her head: a molar in the lower jaw, with a sharp inner edge. The sore had all the characters of an epithelioma, and involved the anterior third of the posterior half of the right lateral half of the tongue, which was much indurated. The glands were, so far as I could make out, unaffected. I recommended extirpation, to which she readily consented. She, with her sister, took a suitable room in the town, and on the 9th I, with two assistants, proceeded to remove the whole organ.

She was put deeply under the influence of chloroform (given on four

thicknesses of towel); and I seized the tongue with a pair of forceps, and transfixed the tip of it with a needle carrying a stout double thread, which was afterwards looped and given to an assistant, by which he pulled the tongue well out of the mouth. I then laterally transfixed the tongue with a blanket-pin, beginning at the right angle of the mouth and bringing it out at the left, and by this means carried the pin immediately in front of the epiglottis. I then placed a single loop of very stout whipcord around the tongue behind the pin, giving it one turn of a knot, ready to be tightened. Next, I divided the attachments of the tongue to the floor of the mouth by means of a pair of scissors, while it was being dragged well out by the looped thread—taking care to hold the face well sideways and close as possible to the pillow. Then I quickly severed the tongue with the whipcord, which cut it much as it would cut hardened butter in frosty weather.

There was very smart hæmorrhage during the time the scissors were being used, and the patient lost, as near as I could tell, about three ounces of blood. There was no further hæmorrhage after the tongue was removed—never a drop from the surface traversed by the whipcord; and no ligature, or even mopping of parts with styptic, was required. The patient remained in bed three days, and went home—on foot, I believe—on the eighth day, a distance of eleven miles.

She had eight months of comparative health, when the cancer returned, this time in the larynx, and ended her life thirteen months after the operation.

I saw, during my student-days, the late Mr. Nunneley of Leeds remove tongues by his method; and afterwards, as an Edinburgh student, I saw the procedure of the late Mr. Syme carried out. In using the *déraseur*, surgeons use the quite unnecessary precaution of waiting each time, after giving the handle a turn, half a minute or more, thinking thereby to prevent hæmorrhage. After a thirteen years' experience of the application of torsion among the so-called lower animals, I am in a position to state that no more blood is lost after the most speedy severance of actively vascular parts by the most rapid strangulation than is lost by the measured torsion at present resorted to. Further, I have not seen, even by Mr. Syme's operation, the tongue and its attachments more completely removed than was quickly effected by my simple proceeding.

## MORPHIA AND A TELL-TALE AS AIDS TO COMPRESSION IN ANEURISM.

By C. F. MAUNDER, F.R.C.S.,  
Surgeon to the London Hospital.

In my Lettsomian Lectures of 1875,\* I drew attention to the value of morphia as an aid to compression, as a substitute for chloroform and its attendant risks. I illustrated its use in the case of a gentleman who "dozed, took his meals, smoked his pipe, and submitted to continuous digital compression for twenty-three hours, with scarcely a complaint; and, at the expiration of this time, expressed himself as capable of enduring treatment many hours longer". The following is another example of the value of the drug.

In February 1877, Mr. —, who is now forty-two years of age, was advised that he was the subject of an aneurism of the popliteal artery. He was put to bed and treated for the first ten days with a bag of shot weighing eight pounds placed over the common femoral artery. During the next month, a tourniquet was substituted, and worn during eighteen hours out of the twenty-four over the superficial femoral artery. His health now began to fail; treatment was discontinued; and he went to his business, the tumour being smaller and pulsation less marked. During the last three months, the swelling and the pulsation had both increased, associated with pain and general discomfort about the knee.

March 29th, 1878. I found Mr. — with an aneurism of the size of a large orange occupying the upper half of the popliteal region, and bulging somewhat to the inner side of it. Continuous digital compression with a weight of ten pounds was advised, aided by morphia, if necessary.

March 30th. Mr. W. R. T. Hawkins and Mr. Albert E. Jones of the London Hospital commenced the compression treatment at 11.45 A.M., the common femoral being the artery selected; and they maintained complete occlusion of this vessel for the space of half an hour alternately. At 4 P.M., the patient suddenly complained of severe pain (distal occlusion?), commencing in the calf of the leg, and running up along the aneurism and femoral artery. A quarter of a grain of

morpha was now hypodermically injected, and relief afforded. From this time, when the gentleman compressing was relieved by his colleague, and the pressure for the moment somewhat relaxed, the force of the pulsation in the aneurism was observed to be gradually diminishing. At 8 P.M., an assistant was recruited, in order to help in the continuation of the compression through the night.

March 31st. At 2 A.M., another paroxysm of pain occurred, after which pulsation was scarcely, if at all, perceptible; and a firm swelling occupied the seat of the aneurism, the disease being practically cured. At 10 A.M., no pulsation could either be felt or seen. One or two arteries could be detected meandering the knee. Compression was continued during the day as a precautionary measure. Throughout the whole time (thirty hours), the patient lay on his back, with the thigh rotated upwards, and the leg flexed at a right angle on this. An indicator (which consisted of a penholder with a piece of paper like a flag placed between the ribs, and which marked the presence or absence of pulsation in the aneurism) was lodged like a finger-post in the flexure of the knee, and acted like a tell-tale to the compressor. Mr. — took food at intervals, and was cheerful and chatty, except when asleep. An injection of morphia was resorted to four times.

The skin over the seat of compression, which had been protected by the occasional application of French chalk, was slightly reddened only, and was the source of the least possible discomfort to the patient, who said he could have borne the treatment many hours longer.

## CASE OF PARALYSIS AFTER APPLICATION OF A PLASTER BY AN UNQUALIFIED PERSON TO THE NAPE OF THE NECK.\*

By E. RICE MORGAN, M.R.C.S. Eng., Morriston.

X. M., AGED 25, living at Landore, workman in a tinworks, had been suffering for about six years from a skin-affection located at the back of the neck; whether sycosis—an unusual situation I admit—or some other cutaneous disease, I am unable to say, for I did not see the man in the early stage; in fact, not until the skin-affection had been effectually got rid of. His previous history was good; he had never had paralysis of any kind before, nor could I find any traces of a specific history; and I have grounds for saying that up to October 1877 he was a strong healthy man.

When I first saw the patient in October 1877, he was in a very dangerous state. His face was very swollen and painful; his eyes were suffused; his tongue was very foul; pulse quick and compressible; throat dry and sore, accompanied by cold clammy sweats; and I came to the conclusion that he was suffering from blood-poisoning, and thought it was probably due to arsenic. At the back of the neck was a large deep slough as large as the palm of one's hand, and I then elicited that, about nine days previously, a certain unqualified practitioner had applied a plaster to the nape of his neck to cure, as he said, the skin-disease. For a few days, the prognosis was very doubtful, and, though I treated him for blood-poisoning from some metal, I was unable to obtain any portion of the said plaster to find out by analysis its ingredients.

These bad symptoms gradually gave way, but, about the tenth day, I found he had lost all motor power in the arms and legs. Sensation, however, was unimpaired; nor did he lose power of speech or consciousness, and he had control over all the sphincters. The spinal cord being, as I judged, implicated high up, I was afraid that possibly the muscles of respiration would become affected; but, fortunately for the man, this did not occur.

After careful treatment, specially with sulphate of magnesia, iodide of potassium, and cinchona, the man quickly improved. The large wound left by the plaster gradually healed; the appetite returned, and with it strength. The return of power to the muscles, however, was very gradual; and it was nearly four months before he could place his hand upon his head; but this improvement has been going on uninterruptedly. His legs, of course, have been much slower in recovering.

March 29th, 1878.—He now looks quite fat, as compared to what he was four months ago. He can take a spoon in his hands, and carry food in it to his mouth, and can give a very fair grip to one's hand. The extensors are less powerful than the flexors. The muscles of the legs during the past month have also made rapid progress; for he is now able, when sitting, to lift them up and keep them out straight for a second. When once put up to stand and allowed to lean against something, he is able to remain thus unaided. Six weeks ago,

\* *Surgery of the Arteries*, pp. 15. London: Churchill.

\* Read before the South Wales and Monmouthshire Branch.

he could not do this. For the past fortnight, he has been amusing himself with one of Maw's galvano-electric machines under my tuition. Lately he has been taking iron and cod-liver oil with a nourishing diet; and I have now every reason for thinking he will make a good and complete recovery.

What was the pathological condition of the spinal cord in this case? What was the poison? Did this plaster, of whatever it was composed, placed over the cervical region, and producing such a deep slough, implicate that portion alone of the spinal cord, causing myelitis or some other condition, or did the poisoning effect of it range over a larger portion of ground, and set up a subacute inflammation of the whole tract of the cord?

I ought to state that the unqualified person, frightened, I presume, at the serious effects of his nostrums, did not claim any payment for his valued advice.

In conclusion, I would beg to suggest that such a case as this ought to be published and widely circulated to warn the ignorant against placing themselves in the hands of quacks; for though, as a rule, their nostrums are harmless, yet we have grounds for knowing, as in this case, that they sometimes use drugs, of the dangerous effects of which they are not aware, but for which they are morally liable.

## CLINICAL MEMORANDA.

### ASPHYXIA SUCCESSFULLY TREATED BY DR. HOWARD'S METHOD OF ARTIFICIAL RESPIRATION.

A SHORT time since, I had an opportunity of testing, in two cases of asphyxia, the value of Dr. Howard's method of artificial respiration.

CASE I.—This was one of diphtheritic croup in which tracheotomy had been performed, and apparently the child had died during the operation; she was pulseless, had ceased to breathe, and the heart-sounds were inaudible. There being no time to lose, I applied the method vigorously, and, in about five minutes, she drew a short breath, which was soon followed by regular breathing. She lived for seven days, eventually dying from the disease for which the operation had been performed.

CASE II.—In another case of asphyxia occurring while a patient was under chloroform—though not arising from that anæsthetic—it was thought advisable also to empty the stomach of its contents. Dr. Howard's method was employed with excellent result, the stomach and even the rectum being emptied almost immediately. The respiration also returned, and the patient, who was about fifty, eventually made a good recovery.

W. C. JAMES, House-Surgeon, Guy's Hospital.

### DIPHThERIA: CROUP: TRACHEOTOMY.

DR. SEMPLE, in his kindly criticisms on my paper (May 4th), assumes that, in the first two cases related, *because* I saw patches of false membrane *therefore* they were cases of diphtheria; and, in the third case, notwithstanding my statement that I saw false membrane flapping through the wound, he assumes, because the other evidences were unfavourable to the diphtheritic theory, that I was in error, and that the case was one of ordinary laryngitis with œdema glottidis, "and that in the worst of them, as is shown in Dr. Bowles's third case, the operation of tracheotomy has a much greater chance of success".

This simply leaves the question where it was; given false membrane, therefore diphtheria. Dr. Moxon and others have demonstrated that false membrane is often present in burns and other traumatic cases; and, in my paper, I adduced positive evidence of a similar kind.

Lastly, Dr. George Johnson, in a contemporary, so far changed his front as to state that bad strains as well as diphtheria are responsible for false membranes. This, from so eminent a physician, is at least an important breach in the walls of the argument; which, if once gained, decides the point that false membrane does not *always* imply diphtheria, and we shall have idiosyncrasy, and local and other, at present, unknown causes rushing in and crying aloud in the moment of victory for their share in the etiology.

Whether it was really false membrane or the lining membrane of the trachea which we saw flapping through the wound I confess I cannot *prove*, but the probability is at least strongly in favour of the former; both Dr. Lewis (not Jervis) and myself are certain it was *within* the trachea, and have no doubt whatever but that the child in its awful struggle for life coughed up and swallowed, as children do, the dangerous if not false membrane which had so nearly cost the little thing its life.

ROBERT L. BOWLES, Folkestone.

## OBSTETRIC MEMORANDA.

### RETENTION OF THE PLACENTA.

ABOUT sixteen years ago, Mrs. G. arrived in London, and was seized with pains and threatened premature birth at about six months. I ordered perfect rest, etc., and matters went on comfortably for a few days, when the fœtus was expelled. The funis was torn off short at the os, which was rigidly contracted; and I determined not to interfere. During the whole time of retention, I was kept in constant anxiety, as periodical flooding came on; and, on one occasion, I took the late Dr. Cape of Curzon Street, Mayfair, with me in consultation. After examination, we agreed nothing could be done but wait patiently. On the nineteenth day, the placenta was expelled in a perfectly healthy condition without a sign of putrefaction.

HUGH DAVIES, Surgeon, 42, Dorset Street, Portman Square.

### RUPTURE OF THE UTERUS.

ON May 29th, 1875, under "Obstetric Memoranda," I published in the JOURNAL notes of a case of rupture of the uterus, which occurred in the year 1853. In that case, the rent was near the fundus, and the symptoms more definite and protracted than in the following one, which has features entitling it to be also recorded.

M. T., aged 37, mother of three living children, and said to have had good confinements, was taken in labour on February 25th, 1878. I visited her at 10.20 A.M. She had had pains since 8 A.M., which seemed natural and frequent. The passages were spacious and lubricous; the os about the size of a shilling, thin but dilatable. The waters had not escaped, and there had not been any show. The head was at the brim, presenting in the first position. The abdomen was more than ordinarily pendulous. Labour did not progress much, although the pains appeared to be strong and at short intervals. She had some warm tea. The os enlarged to about half-a-crown, and, a little before 12 A.M., the membranes were broken, with a view to relieve distension and change the character of the labour. The head advanced into the brim, and the patient remarked that she "could feel it getting lower". There was not any complaint of fixed pain in the abdomen. The progress being slow, which I attributed to the size of the head (the patient stated that she was a month over her time), I left at 1.55 P.M., as I resided within two hundred yards, and promised to return in half or three-quarters of an hour, with direction to send if I were required. I returned at 2.45 P.M., and, directly I entered the house, the nurse told me the pains had ceased, and she thought the woman was dying. I made a rapid examination: the os was well dilated, and there was no hemorrhage into the vagina. The upper part of the head was firmly wedged in the pelvis. The patient said, "Lift me up; give me some brandy", and directed me to a cabinet. I immediately gave her some port-wine, which she swallowed. She was pulseless, evidently moribund from shock (syncope), not from asphyxia or coma. I next gave her a teaspoonful or two of whiskey, meanwhile slapping her face with a wet towel; but she died, with slight convulsive twitches about the mouth, at 3 P.M., a quarter of an hour after my return. Myself and the nurse were the only persons in the house at the time of death; hence I did not feel justified in performing gastrotomy, or in attempting to effect delivery *per vias naturales*. The death surprised myself as much as others. In public practice, an endeavour would, of course, have been made to rescue the child.

A *post mortem* examination was obtained twenty-one hours afterwards. The examination was made in a dark inconvenient room, on a low bed, in the presence of Drs. Byerley and Craigmile. Only the abdomen was investigated, which was extremely prominent. Section was made from the mid-thorax to the pubes. The abdominal parietes were very thin and free from fat. The uterus was exposed, and above the pubes a triangular effusion presented itself under the visceral peritoneum, which membrane was unruptured. About one pound of dark clots was removed, and much fluid blood with a sponge, when a rent was discovered just above the os pubis, anteriorly, extending to about one-third of the circumference of the lower segment of the uterus, through which the fingers could be introduced against the fetal head. The muscular tissue of the womb was torn in a ragged manner, similar to (allowing for difference of structure) laceration of the corpus striatum in cerebral hemorrhage. The rupture had evidently happened at the thinnest part of the uterine wall, about opposite to the greatest diameter of the cranium of the fœtus. An incision was made from the fundus to the cervix, and the child, a girl, seen *in situ* in the first cranial position. The upper part of the head was wedged into the brim, requiring force for its extraction. The child was large, especially its head, and the placenta implanted at the fundus posteriorly. The uterine tissue

was pale, pink in colour, about an inch in thickness at the fundus. Dr. Craigmile kindly examined specimens from the margin of the rent and also from the fundus. He found the involuntary muscular fibres everywhere perfectly healthy, not showing the slightest trace of fatty degeneration or of infiltration. Sections of the hardened uterus confirmed his observations.

In such a case, the only explanations of the abrupt collapse were plugging of the great vessels, concealed hæmorrhage, or rupture of the uterus. The symptoms were syncopal in kind, and there was not the breathlessness associated with embolism or thrombosis. Moreover, the symptoms were very sudden as a result of rupture, and there had not been any previous complaint of pain. Hence, prior to the examination, I could only attribute the death vaguely to shock. The rupture occurred at a very usual spot; namely, near the junction of the uterus and vagina, and at an early period of labour, which is also common. When did the laceration take place? The pains existed at 2 P.M., and at 3 P.M. the patient died. According to Dr. Rigby (*System of Midwifery*, 1853), the posterior wall is slightly more obnoxious to the lesion than the anterior, but they appear to be almost equally liable to the injury. The case is interesting as a contribution to obstetrics, especially in its medico-legal aspects, concerning an accident which, though familiar, is comparatively rare. A moral may be drawn from the absence of interference with the labour, as, had any manual or instrumental procedure been resorted to, the rupture might have been ascribed to violence rather than to the spontaneous efforts of parturition.

W. BOYD MUSHET, M.B. Lond., M.R.C.P.

### ANENCEPHALOUS FETUS.

ON May 5th, 1878, I was sent for to attend Mrs. C., a multipara, who had been in labour twelve hours. On examination, I found the face presenting, and that the cranium was wanting. As the pains were weak, though constant, and the woman was exhausted, I assisted delivery by traction during the pains, firmly grasping the face with my left hand. The placenta came away naturally. The child proved to be an anencephalous monster, as I expected; its limbs moved spasmodically, and its heart beat strong and regularly for about twenty minutes after the funis was severed, but it never breathed.

On *post mortem* examination, the body was that of a fully timed female child, without calvarium or brain. The spinal cord terminated in a thickened membrane, which was attached to the interior of a small piece of bone occupying the occipital region. The face was fully developed; the eyeballs, which were very prominent, forming the summit. The internal organs were normal. The lungs contained no air; small portions sank in water.

I had attended the woman between four and five months previously for threatened abortion; the symptoms being accompanied by considerable hæmorrhage, caused by falling and striking her abdomen against a doorstep.

The interesting part of this case is the fact that the fetus, after sustaining so severe an injury as to arrest the development of the brain, etc., should have reached maturity *in utero* and been born with signs of life. I believe such cases are rare.

T. WELLS HUBBARD, M.R.C.S. Eng., Lenham.

## SURGICAL MEMORANDA.

### A BLOODLESS METHOD OF PERFORMING TRACHEOTOMY.

DR. BOWLES, in the *JOURNAL* for April 27th, places before the profession with great clearness a difficulty with which the country practitioner has often to deal, which, at certain seasons of the year, he has independently to combat, which, without doubt, causes him intense anxiety, often places his reputation at stake, and, therefore, commands his whole power of self-confidence and strength of presence of mind. I do not wish to enter into the pathologico-anatomical controversy on croup and diphtheria at the present moment, nor to enter into the differential diagnosis between the two. My intention, in this communication, is merely to tend, if possible, to remove the principal feeling of anxiety and danger which naturally associates itself to the mind of the general practitioner when the urgent necessity shows itself; the question of life or death is an immediate one of performing the operation of tracheotomy.

We all know that the statistics in favour of tracheotomy below the age of three are not very favourable, some practitioners in Germany even refusing to perform the operation in croup or diphtheria, while some of the hospitals deny admission to the patients, as it increases

the mortality percentage of their operative treatment to a very great extent. Out of 504 patients on whom the operation of tracheotomy was performed in diphtheria, at Professor von Langenbeck's clinic during the last six years, 357, or 70.8 per cent., died. The sole indication for the operation was the laryngeal stenosis. The causes of death were principally lobular pneumonia, croupous exudation, extending into the bronchi, asphyxia, exhaustion, paralysis of the laryngeal and pharyngeal muscles, and collapse.

The immediate danger and the sole cause of alarm to the inexperienced operator in performing the usual operation of tracheotomy is the bleeding. The operation I am about to describe, which may be considered entirely bloodless, is the one at present almost universally adopted in Germany when operating on children.

This operation of tracheotomy superior was first performed by Bose, Professor von Langenbeck's very able assistant, and is carried out in the following manner. The little patient is slowly chloroformed, the mask being somewhat raised from the face if a paroxysm of coughing should set in. (I have constructed a chloroform-apparatus which may be regarded as an extensively modified Junker's inhaler, by which the amount of chloroform inhaled can be exactly regulated, and the whole apparatus worked with one hand, leaving the assistant the other hand free to feel the pulse, etc., and to assist the operator. This apparatus is in use at some of the Berlin hospitals.) As soon as the patient is chloroformed, a roller is thrust under the neck and the head allowed to fall backwards; this will give the front of the neck an arched appearance, and will throw the important parts into prominence. The operator now seeks the upper margin of the cricoid cartilage with the tips of his fingers, and makes a vertical incision through the skin exactly in the middle line of the neck, beginning about a small finger's width from above the upper margin of the cricoid, and extending about an inch and a half to two inches downwards. The incised parts are drawn asunder, and the cricoid cartilage is thus so far exposed that, after steadying it with a finger, a transverse incision of not quite half an inch in length can be made as near its higher margin as possible. By this incision, the fascia which envelops the thyroid gland and connects it with the trachea is divided through. With a pincette, the operator now seizes hold of the lower border of this transverse incision, and, in the same way as the periosteum is levered off from the bone in a subperiosteal resection, he severs the fascia off from the trachea in a downward direction either with a blunt hook or a director, pushing downwards with the fascia all those veins which cause so many difficulties. As the operator gradually descends with the director, he unloosens the isthmus of the thyroid gland from the trachea, pushing the gland outwards and downwards, and lays the upper tracheal rings quite bare, so that they can now be seized and opened in the usual way.

This operation is particularly applicable to children, especially in those cases where immediate danger is apprehended and the operation is to be performed at once. It is certainly preferable to the operation of tracheotomy inferior, which is performed below the thyroid gland, where the trachea lies much deeper and is covered by an extensive plexus of veins. In the operation just described, which is made above the isthmus of the thyroid gland, the number of cartilage-rings that can be exposed and cut into, will of course be more limited than in the inferior operation, and will depend to a great extent on the size of the gland; but it will also permit, should it be deemed necessary to enlarge the opening, to extend the incision upwards by dividing the cricoid cartilage, which in children none need hesitate to do.

Another great advantage in this operation is the fact that it does away with a staff of assistants. An intelligent nurse alone will be able to do all the assistance that is required. The incised parts can easily be kept asunder with a large strong hair-pin, somewhat stretched to represent a large V, the free ends bent into half-hooks; or two small hair pins can be selected, the free ends bent and inserted under the incised parts on opposite sides, while the head of one pin is fastened to a piece of elastic, which passes round the back of the neck to the head of the other. This operation need but be practised once or twice to insure confidence.

LOUIS HENRY, M.D., L.R.C.P., Amptill Square.

## THERAPEUTIC MEMORANDA.

### THE KORONIKO PLANT.

SEEING a paragraph in the *Evening Standard* of May 10th referring to the koroniko plant of New Zealand (erroneously spelt "roromiko") as a newly discovered remedy for diarrhoea, I write to say that I can

fully endorse the statement as to its efficacy as an astringent. I have often used it in an up-country district in Hawkes Bay, New Zealand, during the last four years, and have found it even more certain in its effects than the ordinary astringent mixtures. It is an old and well-known remedy amongst the Maories and up-country shepherds, especially for intestinal disturbances arising from drinking stagnant swamp-water in dry seasons. The usual method of using it is by making a strong infusion of the young leaves. The koroniko is a species of broom. I have no doubt that it would make a valuable addition to our *Pharmacopœia*.  
JOHN ARTHUR FRANCIS, Southsea.

## REPORTS

OF

### MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN AND IRELAND.

UNIVERSITY COLLEGE HOSPITAL.

DR. GOWERS' CLINIQUE.

*Anæmia Estimated by the Hæmacytometer.*—To ensure greater accuracy in clinical investigations, Dr. Gowers employs the hæmacytometer, a modification of Hayem's instrument, for the purpose of ascertaining the number of red and white cells in a given volume of blood. The essential part of the apparatus consists of a glass slip, on which is a cell one-fifth of a millimètre (.0008 inch) deep. The bottom of this cell is divided into one-tenth millimètre squares. Upon the top of the cell rests the glass cover, which is kept in its place by the pressure of two springs. In estimating the number of corpuscles, the patient's finger is pricked; then, by means of a capillary pipette, five cubic millimètres of blood are taken up and well mixed with 995 cubic millimètres of saline solution; a drop of the dilution is then placed in the glass cell, the cover is adjusted, and the slide is placed in the field of a microscope. In a few minutes, all the corpuscles have sunk to the bottom of the cell, and are seen lying on the squares; the number of corpuscles in ten squares is then counted, and this, multiplied by 10,000, gives the number in a cubic millimètre of blood. The degree of dilution and size of the squares are so proportioned that, with normal blood, two squares contain about 100 corpuscles, and the number in two squares thus expresses the percentage proportion of corpuscles to that of health. The proportion of white corpuscles to red, or their absolute number, may be easily determined during the same observation.

An extremely anæmic woman came under treatment as an out-patient on February 20th; the percentage of red corpuscles was found to be 48. She was ordered liquor ferri chloroxydi, and the blood has been examined almost every week since; the percentage of corpuscles has steadily increased, so that within five weeks it has risen to 98; the successive enumerations having given 47, 56, 68, 85, 98 per cent. It is noteworthy that the colour of the blood has not increased in proportion to the increase of the corpuscles, and this appears due to the increase of the number of corpuscles being out of proportion to the increase of the hæmoglobin, which, when the last observation was made, was only one-third of the normal. This is an interesting fact, as showing that iron is capable of increasing the formation of blood-cells, apart from an increase in the hæmoglobin.

A woman, the subject of lymphoma of the neck, presented a florid countenance, but the conjunctiva and lips were rather pale. The blood, as drawn from the finger, when she first came on January 16th, showed 52 per cent. of corpuscles, without any appreciable increase in the number of the white cells. She was treated with phosphorus, in doses of one-thirtieth of a grain, three times a day, gradually increasing the daily dose until she is now taking the one-thirtieth of a grain six times a day. She has several times begged for an increase in the dose, being certain that she was improving, and once spontaneously doubled it; with the effect, however, of causing sickness. There has been a slight diminution in the size of the glands and a very marked increase in the number of red blood-corpuscles, which have risen from 52 per cent. on January 16th to 66 per cent. on February 27th, and 74 per cent. on March 26th. No other drug has been employed, and the patient's conditions of life have remained the same. A precisely similar result has followed the use of phosphorus in another case of the same disease, in which the red globules rose from 52 to 80 per cent. This influence of phosphorus is remarkable when compared with some of its effects, and further observation on the point is needed; but it is in harmony with the observations of Dr. Broadbent, and it is of interest in connection with the benefit observed by Dr. Byrom

Bramwell to result from the use of its congener arsenic in pernicious anæmia.

*Secondary Arthritic Changes in Nerve-Lesion.*—A woman attending presents now arthritic changes in the fingers, preventing the extension of the joints, with slight wasting of muscles. The case might be mistaken for a primary rheumatic disease, but for the absence of thickening around the joints, and the history, which is of much interest. Several months ago, an incised wound in the palm divided the termination of the ulnar nerve, causing immediate paralysis of all the muscles supplied by it. From the paralysis of the interossei, the fingers assumed the characteristic position: extension at the proximal, flexion at the middle and distal joints. An ascending neuritis followed, with pain and tenderness as high as the brachial plexus, relieved ultimately by free blistering; voltaism having given only slight relief. The injured nerve and paralysed muscles gradually recovered; but, during the paralysis, secondary arthritic changes occurred, probably caused in part by the nerve-lesion, and persisting so as now to lessen greatly the use of the recovered power, and simulate primary joint-affection with slight secondary wasting of muscle.

*Epilepsy, with Constant Vertigo, Sensory Aura, and Monocular Diplopia.*—This unusual combination is presented by a young man now attending, who has been liable to occasional fits all his life, frequent during the last few years, always occurring in the morning, the convulsions being greater on the left side, which is slightly weak. The fits commence by jerking of the left hand, sparks of "the colour of fire" before the left eye, and inability to hear with the left ear. There is a constant tendency to fall to the left, so that in walking he is obliged to keep the wall on his left hand. Hearing is recovered on the left side to about half its sensibility; the sight of the left eye is of normal acuity; but, on closing the right eye, all objects in the right half of the field of vision appear double, the two images being separate and side by side. Formerly, this diplopia obtained over the whole field, except in central vision. The patient had been seen on one occasion by Mr. Edward Nettleship, who had failed to find any cause for the diplopia or error of refraction. Dr. Gowers thought it possible that both the diplopia and the deafness were the effects on the periphery of the discharging change in the perceptive centre, just as the weakness was probably the consequence of the convulsions.

## REVIEWS AND NOTICES.

LECTURES ON SURGICAL ANATOMY. By JOHN CHENE, M.D., F.R.C.S.E., F.R.S.E., Assistant-Surgeon to the Royal Infirmary, Edinburgh.

THE object of this manual is to point out the practical bearings of anatomical details, and, by providing a number of carefully executed engravings, to encourage the student to make for himself drawings of his dissections. Anatomy may be looked at from a morphological, from a surgical, and from an examinational point of view. This latter, often through the influence of examining boards, gains the greatest consideration: the morphology seems only capable of existing in the larger universities; hence the necessity of contenting ourselves with looking at anatomy from the more practical, if less scientific, surgical aspect. This is happily rendered easy by such a manual as we have now before us. Already, in some Continental schools, chairs of surgical anatomy exist; and in this country, the use of works which present to the student anatomical details, so arranged that he is at a glance able to understand their practical bearings, has been long recognised.

The plan of the book is extremely simple, and there is never any difficulty in understanding exactly what is meant, and in being able to find good reasons for all the conclusions arrived at. The object seems often to have been rather to indicate the principal points than to treat the subject in an exhaustive way, thus enabling the student to have the satisfaction of filling in the details from his already acquired knowledge of anatomy and surgery. So much has the surgery introduced increased our interest in the pages, that we almost wish that, after the manner of French authors, Mr. CHENE had gone more fully into practical details.

Each region is treated separately: the much neglected external anatomy is described, and the structures met with in each region: the changes resulting from dislocations, fractures, etc., are mentioned; and the relations and anastomosis of the vessels fully and accurately gone into.

From the chapter on the elbow-joint, we extract the following. "The sterno-clavicular joint is ligamentously strong, its movements are restricted; the shoulder-joint is muscularly strong, its movements are extensive. Both joints are osseously weak. The elbow-joint is

osseously strong, and ligamentously strong as regards lateral displacements. The strength is such that there is no lateral movement. On the other hand, the strength of the joint in the antero-posterior direction is osseous and muscular; but the bones are so shaped that the movements in this direction are extensive. In these three joints of the upper extremity we have examples of the three sources of joint strength—bone, ligament, muscle. In the lower extremity, it will be found that the hip-joint is strong osseously, ligamentously, and muscularly; the knee-joint ligamentously; and the ankle-joint osseously." In the chapter on Colles's fracture, we find the difference between *penetration* and *impaction* pointed out. "Penetration is the passage of the one fragment into the other; when the distortion cannot be remedied by any justifiable force by the surgeon, then impaction has occurred."

In plate v, fig. 1, the ulnar artery might have been represented behind rather than superficial to the tendons; and in plate vi, fig. 2, reference might have been made to the vein constantly met with at the root of the thumb in excision of the wrist.

The displacements produced by the muscles around the hip-joint and by those of the thigh and leg are mentioned; and, from a consideration of the actions of the latter muscles, "a combination of the long splint to prevent eversion, and the extension apparatus to counteract shortening, along with lateral or anterior and posterior splints, according to the situation of the fracture, is recommended as the most efficacious way of treating the majority of cases of fracture of the femur". For Syme's amputation at the ankle-joint, the following rule is given. "Find the tip of the external malleolus, find the point on the inner ankle directly opposite, the foot being held at right angles to the axis of the leg. Join these points by the shortest road, first across the sole, second across the dorsum of the foot." We miss a figure, showing the vessels and nerves, which the surgeon requires carefully to preserve in the long skin flap.

In the next division, the anatomy of inguinal and femoral hernia is described, also the structures met with in the several operations for lithotomy; in ligation of the iliac arteries; and in performing colotomy. And in the last division, the regions of the cranium, face, neck, and thorax, are each described separately. The cervical fascia and the structures met with in performing the operations of tracheotomy and laryngotomy are so carefully described, that the student will rather have a difficulty in forgetting than in remembering their relations.

Amongst the numerous figures are a series of beautifully clear transverse and longitudinal sections, through the upper and lower limbs, which enable the surgeon at a glance to see the exact relations of the structures he is likely to meet with in performing operations on the living subject.

The work is well worthy its author; and the student will, after its perusal, on account of its simplicity and freshness, have his interest in anatomy increased, and be better able to bridge over the widening channel between anatomy and surgery, and to understand the intimate relations which must ever exist between them. So difficult is it to draw the line between surgical anatomy and operative surgery, that we might suggest to the consideration of Mr. Chiene the advisability of so extending this manual that it will include both.

## NOTES ON BOOKS.

*Sayre on Spinal Disease and Spinal Curvature: their Treatment by Suspension and the Use of Plaster of Paris Bandage.* London: Smith, Elder, and Co. 1877. In this book is described the method of treatment of spinal curvatures by the plaster jacket suspension, of which much has with great reason been heard. It is unnecessary to criticise in detail a book the substance of which is known to very many, and of which the whole contents should be read by every practitioner who is at any time called upon to treat a case of lateral curvature or of Pott's disease. The method of treatment is fully described and illustrated by excellent photographs; so that henceforth every practitioner can treat such cases for himself with little expense or trouble to the patient, and very rare recourse indeed to the instrument-maker. This little book makes a revolution in surgery, and renders simple, easy, painless, and promising a class of cases which have heretofore been the plentiful cause of life-long pain, deformity, decrepitude, and misery; and when curable, have been so commonly by tedious, complicated, and wearisome methods. A good deal of discussion has arisen as to the first beginnings and earliest hints of the method of treatment of spinal curvature by suspension and the plaster jacket which Dr. Sayre has devised and brought to so much perfection, and which we ventured at once to pronounce a great and permanent advance in the healing art. Dr. C. T. Hunter of Philadelphia finds, in Glisson's *Treatise on Rickets* (edition of 1668, page 363), the following

description of the suspension method. "The artificial suspension of the Body is performed by the help of an Instrument cunningly made with Swathing-Bands, first crossing the Breast and coming under the armpits, then about the Head and under the Chin, and then receiving the Hands by two handles, so that it is a pleasure to see the Child hanging pendulous in the Air, and moved to and fro by the spectators. This kind of Exercise is thought to be many waies (ways) conducive in this Affect, for it helpeth to restore the Crooked Bones, to erect the bended Joyns, and to lengthen the short Stature of the Body. Moreover, it exciteth the vital Heat, and withall alureth a plentiful distribution of the Nourishment to the external and first affected parts; and in the meantime it is rather a pleasure than a trouble to the Child. Some, that the parts may the more be stretched, hang Leaden Shoes upon the Feet, and fasten weights to the Body, that the parts may the more easily be extended to an equal length. But this exercise is only proper for those that are strong." Dr. Sayre's method of treatment is daily becoming more generally applied in this country, since his brilliant demonstrations at the Manchester meeting of the British Medical Association and the publication of his book. Besides the admirable results achieved by Dr. Macnaughton Jones of Cork, described in the pamphlet which he has published, and the extensive and successful applications by Mr. Howard Marsh, Mr. C. Heath, and Mr. Berkeley Hill in London, Dr. Macleod in Glasgow has recently publicly demonstrated its successful application there; and Mr. Golding Bird, at Guy's Hospital, has employed it in a large number of cases, of which we shall shortly publish his notes. The results achieved appear, with ordinary care, not only to be uniformly good, but such as heretofore would have been impossible. The simplicity of the treatment, the facility which it affords for locomotion and open-air treatment, its cheapness, its ready adaptation to the needs of the poor and to the everyday practice of the general practitioner, the ease and freedom from pain which it confers, and the ultimate cure which it rarely fails to secure, place it among the most valuable resources of practice, and stamp it as an inestimable boon to humanity. The practical genius, the generous energy, the apostolic fervour which Dr. Sayre devoted to its perfection and to the mission of popularising its use on both continents deserve to be remembered among the most admirable achievements of modern surgery. The book itself is interesting as a novel; it bears the stamp of a peculiar individuality; it is written with a strong enthusiasm; and has exaggerations of style and manner which may readily be excused by all, while, by many to whom the author became known, they will be welcome as recalling the peculiar idioms and combined genius, humour, pathos, and ruggedness which made Dr. Sayre a striking and memorable figure in all the surgical assemblies in which he was seen during his visit to this country.

*Chorea and Whooping-Cough*, by OCTAVIUS STURGES, M.D., F.R.C.P., London, Smith, Elder, and Co., is an original study by Dr. Sturges of two diseases of which the pathology is still quite unsettled. Dr. Sturges, who has had good clinical fields of observation at the Westminster and the Children's Hospitals, treats whooping-cough as a result of "conveyed nervous impression". It is, however, extremely difficult to reconcile what is known (and accepted by the author) of the contagious character of whooping-cough with the view that it is, like chorea, an essentially functional nervous disorder. As to chorea, Dr. Sturges holds also a theory that it is essentially "functional"; but here again he is confronted, on the one hand, with the relationship of chorea to precedent rheumatism, and, on the other, with the progress of cerebral localisation as a physiological doctrine, which in its proved pathological relation would destroy the view which he advances. On the whole, we cannot admit that Dr. Sturges has made out even a good *prima facie* basis for his views. Nevertheless, like all intelligent studies from nature, these lectures afford interesting and useful reading, and especially so in so far as they accentuate the neurotic side of attacks of whooping-cough.

*The Journal of Anatomy and Physiology*, conducted by Professors Humphry, Turner, and McKendrick, flourishes none the less vigorously for the fissiparous division which has given life to Dr. Michael Foster's *Journal of Physiology*. The April number, Part III, 1878, is full of good material; among which, particularly interesting to medical readers, are Dr. Creighton's paper on a Pathological Function of Periosteum, illustrating in a striking and original manner its bone-forming function as related to new and malignant growths; Do Bacteria or their Germs exist in the Organs of Healthy Living Animals? by Mr. Chiene of Edinburgh and Mr. Ewart of University College—an experimental investigation leading to a negative reply; and the continuation of Dr. J. W. Dadd's very thorough analysis of the evidences of Localisation of the Functions of the Brain.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 25TH, 1878.

MEDICAL TITLES.

A CORRESPONDENT at Manchester, an M.B. of Edinburgh, writes to us:—

"I take this opportunity of venturing to opine that a great deal of space is allotted to childish whimperings for 'M.D.' from men who had at the proper time not either the steadiness or their fathers the money to enable them to graduate. Although we are distinctly opposed in this matter, I trust you will accept my expression of opinion in a spirit of kindness."

We take the observations of our correspondent in very good part. The grievance of English medical men is, however, not so much, in our opinion, that it is difficult for them, or often impossible, to obtain the title of M.D. after they have entered the profession, as that it is not possible for them to obtain it under ordinary conditions of graduation except by undergoing, like our correspondent, a part of their education in Scotland or Ireland. The provision for conferring university diplomas in medicine on English students of medicine is exceedingly defective, and they are placed at a great disadvantage as compared with the students of Scotland and Ireland. The regulations and examinations of the Universities of Edinburgh, Glasgow, and Aberdeen, and the Queen's Universities, are such as place the degree of Doctor of Medicine within the reach of the great majority of Scotch and Irish students, without any unusual sacrifices of time or money, and without going beyond the ordinary standard of fair preliminary education and good medical instruction, such as are attained by the majority of students, who, being educated in London, Manchester, Liverpool, Birmingham, etc., enter upon practice with the diplomas of the London colleges. The degree of Doctor is no doubt valuable in the public mind, and is, we are told by a stream of correspondents, often important socially and in practice as being supposed to imply a higher degree of preliminary education and medical knowledge. In other words, if two gentlemen settle in a country village or in a town district, one of whom claims an university title to the prefix Doctor, while the other, if he style himself a doctor at all, only does so by reason of that courtesy title which many conceive to attach to the diploma of a physician licensed by a chartered college of physicians, the former has a decided advantage in the first instance and so far as diplomas can give it; of course, personal qualifications in the end settle the question of success more than the possession of parchments, but that is beside the question at issue.

Now, it will hardly be contended that the annual hundreds of practitioners turned out by the metropolitan and provincial medical schools of England, armed with triple diplomas, are less completely educated and equipped for practice than the average diplomates of Dublin, Glasgow, Aberdeen, etc. The difference of the title they bear represents, in fact, little more than the local accident of their birth and place of education, and the form of charter given to the licensing bodies of those places.

Here we see once more the pernicious effects upon the profession in England of the contempt with which the older English universities have treated the study of medicine. The University of London gives only "fancy degrees". Its examinations are so framed as to exclude the multitude of students from attempting to take them. Oxford deliberately suppresses medicine except as the luxury of the few,

with which she is only collaterally concerned. Cambridge is striving with some success to popularise and extend her school, but still can only expect or desire the *élite* of the students, and a moderate number of them. The vast majority of students of medicine in England have been, and are, excluded by present arrangements from university diplomas. Nevertheless, they are as well able to pass university examinations of the good average type accepted in Scotland and Ireland as their more fortunate colleagues in those sister parts of the kingdom. We are distinctly of opinion that there is here a substantial grievance, and one which in any complete system of medical reform ought not to be overlooked. As to the irregular use of courtesy titles, that appears to us to be the natural result, however much open to objection, of the substantial injustice and inequality of the existing state of things. We do not, for instance, clearly see why a member of the London or Edinburgh College of Physicians is not as naturally entitled to the courtesy style of doctor as our correspondent, who is a bachelor of medicine. All social anomalies have a tendency to right themselves in more or less irregular ways. If there were any substantial difference in the medical education and qualifications of an M.R.C.P. of London and an M.B., say of Durham or Edinburgh, which implied a distinct professional difference, we should not find a very large number of reputable gentlemen adhering to the courtesy title of doctor in virtue of their physicianship. But, although technically there is a difference, substantially there usually is not; or, where there is, the balance of educational superiority and accomplishment is as likely to incline on the side of the London physician as of the Scotch or Irish graduate. It is the substance rather than "the show of things" which ultimately decides the settlement of such questions. The legislative bestowal of charters and nomenclature of degrees has been a thing of slow irregular growth in our country, assuming various shapes in different parts of the kingdom, and according to the fashion of the period at which these legal powers have been bestowed. No one can doubt that, if a homogeneous system of examining for diplomas and degrees were to be now established, the same medical grade would be bestowed upon the metropolitan or provincial English students who pass the preliminary examinations and final professional examinations of two or more of the medical corporations as on the graduates of many of the degree giving universities of the United Kingdom. The question of inequality of title has, of course, only become prominent since the Medical Act has conferred equal rights of practice in all parts of the kingdom on all diplomas and degrees conferred in every part of it.

We are far from agreeing, therefore, that the complaints of Englishmen entering upon the practice of medicine, or desiring to improve their legal status in it, as to the difficulty of obtaining the title of "Doctor", to be "childish whimperings". The fault lies neither in their "want of steadiness", nor in niggardliness of their fathers, but in a definite legislative inequality, to which we have more than once referred, and which does not exist in any other country in the world. In our opinion, this is an important point of medical reform, of which the interest will become more generally recognised, and which will, sooner or later, come to the front as calling very urgently for a just solution, such as will satisfy fair requirements without injuring individual interests.

MEDICAL REFORM: DIRECT REPRESENTATION OF  
THE PROFESSION IN THE GENERAL MEDICAL  
COUNCIL.

SOME of the grounds on which the Association bases its claim for the direct representation of the profession may be briefly recapitulated.

That the Association, by its influence in obtaining the Medical Act, 1858, first called the General Medical Council into existence.

That direct representation of the profession in the Council was distinctly promised to the Association when the *Register* of the profession—one of the objects of the Medical Act—should be completed.

That the present composition of the Council is objectionable, on the grounds of its comprising an overwhelming proportion of corporation representatives.

That Corporation interests have consequently occupied too much of the time of the Council, to the undue exclusion of general and professional interests.

That medical reform has been obstructed by the conflicting interests of the universities and of the corporations, as was the case before the Medical Act of 1858.

That owing to the preponderance of corporation representatives in the General Medical Council, the Council has completely failed to agree respecting either of the two great principles of medical reform.

That the interests of the corporations and of the lecturers connected with them have been the great barrier to the establishment of conjoint boards of examination.

That the sittings of the General Medical Council involve an expense of about £400 for one day, and of about £160 day by day during prolonged sessions.

That, though the greater part of the sittings of the Council has been devoted to the interests of the corporations, the universities and corporations do not contribute to the payment of their representatives upon it.

That the profession, as distinct from the Crown, the universities, and the corporations, found the whole of the fund, amounting to many thousand pounds, on which the Council commenced its sittings, and still maintains it by registration fees.

That direct representatives will have no private or corporate interests to watch over, but will naturally devote themselves to advocating the needs of the profession and of the public.

That direct representatives will improve the Council by balancing the present undue weight of the corporations, will increase the interest and confidence of the profession in its proceedings, and will obviate any antagonism which may unfortunately exist or arise between the General Medical Council and the profession.

That the demand for direct representation is in accordance with the almost unanimous voice of the British Medical Association and of the profession, as tested by the decision of the Association at each annual meeting from 1868 to the present time.

That a canvass of the profession has been recently made by the Medical Reform Committee of the Association: 1. As to direct representation of the profession in the General Medical Council; and 2. The compulsory formation of conjoint examining boards in each division of the kingdom on the principle of equal fees and uniform examination.

That the returns received up to the 18th instant are as follows:

	Aye.	No.
Direct Representation .. .. .	5975	121
Conjoint Scheme .. .. .	4310	264

Returns are still coming in, and the replies observe the same proportion. Petitions also have been presented to the House of Lords; and in some places the signatures to the petitions in support of both principles have doubled the replies to the circulars of the Reform Committee received from them.

As was stated in the last number of the JOURNAL, the Council of the Lancashire and Cheshire Branch of the Association, the largest in the kingdom and comprising the flourishing medical schools of Manchester and Liverpool, where a complete education in medicine, surgery, and midwifery is given to a large number of students, unanimously resolved to oppose any Bill which did not grant direct representation and provide for the compulsory formation of conjoint examining boards.

In 1868, the late Dr. Parkes suggested that, if the profession persisted for another year in the demand for direct representation, the claim might then be conceded. Ten years have since elapsed, and the

claim has been made year after year, but the Council have not even discussed it. The present Bill of the Government, when submitted to the General Medical Council, did not provide for the compulsory formation of conjoint examining boards; but that point was fully discussed and voted upon, though it was much to be desired that the vote had been of a more decided character than was indicated by a division of fourteen against ten. The question of direct representation merited equal consideration.

Medical reform is not only submitted to the General Medical Council. In 1857, the Government applied to the Association, to ascertain its views on the subject; and that the Association must now and ever play an important part in connection with medical reform, is a fact which the past history of the Association makes inevitable. The object of the Association has ever been to secure a measure of reform beneficial to the public and just to the profession. It has acted with the greatest forbearance in endeavouring to conciliate support both from the General Medical Council and from the Government. The reproach cannot honestly attach to the Association of any failure that may occur. It has striven earnestly. It has worked openly and fairly, publishing year by year a full and distinct account of its proceedings. Conciliation and co-operation have been its guide-marks in relation to the Government and the General Medical Council. It is fortunate in having secured the support and alliance of the Irish Medical Association, which, as the exponent of professional feeling in Ireland, indorsed the views of the Association. To imagine that the Association can abdicate the position it attained before and at the time of the passing of the Medical Act of 1858, and that it alone is to be excluded from all influence in the present conjuncture, will probably prove to be a fatal delusion.

#### TUBERCLE.

THE question of Tubercle seems entering upon a new and somewhat unexpected phase; indeed, it seems to require the mental agility of a pathological acrobat to understand the series of transformation scenes to which we have been treated. As our readers are aware, since Schiippel's discovery of "giant-cell systems" in scrofulous glands, there has developed a remarkable view that "giant-cell systems" are characteristic of tubercle; this has been maintained by Hering, Buhl, and others on the Continent, and adopted by Green, Hamilton, and many pathologists here. Virchow's followers have shown that giant-cell systems are distinctive of, not tubercle, but cells undergoing caseous degeneration under any and all circumstances; but this has not been regarded. Now, certain eminent French authorities, headed by Professor Charcot, affect to maintain Laennec's views, "slightly modified". They argue thus: Tubercle is characterised by the presence of giant-cells; all caseous deposits in the lungs and glands, at certain stages, may be found to contain tubercle; therefore, all such products are tubercular; and M. Charcot thinks that the "independent existence of caseous pneumonia requires to be supported by new facts". Thaan considers all strumous inflammations tubercular, or rather that all tubercle is the expression of the strumous diathesis; and that, as giant-cell systems are found in strumous glands, tubercle is only a specific product of strumous inflammation. The question of tubercle seems to us to hinge upon this: Is it a specific growth allied to the sarcoma, or is it an inflammatory product? If it be a specific growth, it is certainly determinable in a manner unlike any other member of the class, as the experiments of a few years back showed; and recently Friedländer (Virchow's *Archiv*, November 1876) produced giant-cells, and all by cutting the recurrent laryngeal nerves in dogs. If it be inflammatory, there is an end to all dispute. If the word tubercle could be allowed to mean no more than "papule" or "pustule", that is, a form of inflammation attacking certain structures and giving rise to certain appearances, but depending upon sometimes local and sometimes general causes, a great step would have been made towards the simpli-

fication of this much-vexed and difficult problem. At present, we feel sure that many teachers must be sorely perplexed in their endeavours to be at the same time honest to themselves, and yet to teach such views as are likely to satisfy examiners.

THE total number of ovariectomies performed at the Samaritan Hospital, during the two years 1876-77, was 132; of these, there were 115 recoveries and 17 deaths, giving a mortality of only 12.39 per cent.

THE late Sir Francis Goldsmid has bequeathed £40,000 to University College, and £10,000 to the Hospital. Sir Francis was for many years, up to the time of his death, treasurer of University College; and was a liberal supporter of the Hospital.

M. CONSTANTIN PAUL considers that the anæmic murmur, heard at the base of the heart, arises in the pulmonary artery. He names it the anemo-spasmodic murmur. Unless the heart be depressed, the murmur is heard in the second intercostal space. It is not constant, because the existence of the element of vascular spasm is necessary for its production.

ON Monday last, the prizes in the Medical Department of University College were publicly distributed by Mr. John Simon, C.B.; and on Wednesday, the successful candidates in the Medical Department of King's College received their prizes from the hands of the Earl of Camarvon.

M. GOUGENHEIM adds, in an observation recently communicated to the Société Médicale des Hôpitaux de Paris, a new observation of cerebral localisation: a case of monoplegia of the left leg, following a fall upon the head; there was no loss of sensation. The diagnosis was cortical lesion, localised in the upper extremity of the ascending frontal convolution. The *post mortem* examination showed a lesion of the ascending frontal convolution, limited to the external surface of paracentral lobe. This corresponds to Ferrier's determination of the psycho-motor centre of the muscles of the lower extremity.

AT the *lêve* held by the Prince of Wales on behalf of Her Majesty on the 17th instant, Dr. Eason Wilkinson, President of the British Medical Association, was presented by Dr. Risdon Bennett, President of the Royal College of Physicians. The presentation list also included the names of the following members of the medical profession: Dr. Matthews Duncan; Surgeon W. Donovan, Army Medical Department; Surgeon H. F. Hensman, 2nd Life-Guards; Surgeon V. Kelly, Westmeath Militia; Mr. W. H. Michael (on being made a Q.C.); Surgeon-Major A. S. K. Prescott; Surgeon J. T. Powell, M.D., 49th Middlesex Rifle Volunteers; Honorary Deputy Surgeon-General C. W. Poulton, M.D.; Surgeon J. J. Routh; Dr. Russell Reynolds, on appointment as Physician to the Household; Deputy Surgeon-General J. Small; and Deputy Surgeon-General W. Williamson.

#### MR. SPENCER WELLS'S LECTURES.

THE following is a programme of the six lectures on the Diagnosis and Surgical Treatment of Abdominal Tumours, to be delivered in the Royal College of Surgeons on Mondays, Wednesdays, and Fridays, at 4 P.M., commencing on Monday, June 10th, by Mr. Spencer Wells. (It is probable that some variation may be found necessary in the precise subject or order of each lecture.) *Lecture I*: Mode of examining Patients with Abdominal Tumours; External, Internal, and Combined Examination; Form of Note-book for recording Cases; Collections of Fluid in the Abdominal Cavity and in Cysts; Ovarian, Renal, and Hydatid Cysts; Illustrated Specimens from Museum; Chemical and Microscopical Examination of Fluids removed by Tapping.—*Lecture II*: Semisolid Abdominal Tumours; Different Kinds of Ovarian Tumours—their Diagnosis—Complications with Pregnancy; Extra-uterine Pregnancy—Specimens illustrating various other Conditions resembling Ovarian Tumours; Fibroid and Fibro-cystic Uterine Tu-

mours; Tumours of Abdominal Wall; Tumours of Omentum and Mesentery, of Liver, Spleen, Kidney, and Mesenteric Glands; Cancer and Tubercle; Aneurism; Hæmatocele and Pelvic Abscess; Faecal Accumulation; Phantom Tumours.—*Lecture III*: Surgical Treatment of Ovarian Cysts and Tumours; Tapping, by Abdominal Wall, Vagina, or Rectum; Tapping, with Drainage; Injection of Iodine, or Antiseptics; Incision and Drainage; Ovariectomy—Selection of Cases—Preparation of Patient—Instruments—Anæsthetics; Duties of Assistants and Nurse.—*Lecture IV*: Details of Different Steps in the Operation of Ovariectomy—Position of Patient—Incision—Adhesions—Opening and Emptying of Cyst—its Removal—Treatment of Pedicle—Closure of Wound—Dressing and After-Treatment.—*Lecture V*: Results of the Operation—History of Recovered Patients—Proportion of Incomplete Operations, and the Results—Cases of Recurrence and Second Operation—Successive Changes in the Mode of Operating and After-Treatment.—*Lecture VI*: Antiseptics in Abdominal Surgery; Surgical Treatment of Uterine Tumours. These lectures will appear in the BRITISH MEDICAL JOURNAL.

#### THE ROYAL HOSPITALS OF THE CITY.

WE desire again to draw special attention to the petition to the Court of Aldermen, which was published in the JOURNAL for May 4th, among the minutes of the Hospital Out-patient Reform Committee, because the Home Secretary has agreed to issue a Royal Commission to inquire into the administration of the Charities of the City; and there seems reason to suppose that, if the Committee were to address itself to him, Mr. Cross would be quite willing to receive a deputation from them, and listen courteously to what they had to say as to including the administration of the city hospitals in the inquiry. We understand that the treasurer of St. Bartholomew's (Sir Sydney Waterlow) is not at all opposed to the most searching investigation being made, and our Committee can hardly allow the matter to remain as it is.

#### CHARGE OF FEVER-PATIENTS.

A QUESTION of importance was tried last week by the justices, at Abingdon, upon a summons taken out by the Great Western Railway Company against the Rev. Charles Martin, the Warden of St. Peter's College, Radley, and Mr. T. Baker, the medical attendant of the college, for having sent one of the pupils home to his parents by train while he was suffering from scarlatina in a highly infectious stage. It appeared that, previously to the breaking-up of the school for the Easter holidays, the Warden sent a circular-note to parents and guardians to warn them that scarlet fever had appeared in the school, but no notice of the fact was given to the railway company. Before they left, the Warden told the boys that if any of them felt ill they were to be examined by the doctor; but no one presented himself, and neither Dunning, the boy in question, nor any other boy, was medically examined before leaving. Nearly all the boys in the school travelled from Radley by the ordinary trains of the Great Western Railway, being provided with money for the journey by the college authorities. On arriving in London, Dunning was examined by a physician, and found to be suffering from scarlatina in a very infectious stage of the complaint. Mr. Martin, speaking on his own behalf, submitted that he was not "in charge" of the boy, nor did he "aid or assist" him to travel within the meaning of the Act or of the by-law. He disclaimed all responsibility for the boys after the final roll-call. With regard to the substantial part of the complaint against him, he not only could admit no want of caution, but insisted that he had done everything that could reasonably be expected of a head-master so circumstanced. At the same time, he regretted that he had not notified to the company that there was fever in the school. Mr. Baker, in his defence, quoted from medical authorities to show that there was no such symptoms in Dunning's case when he saw him as ought to have led him to diagnose scarlet fever, and that he was justified in attributing the symptoms to other causes. The bench dismissed both summonses. The *Pall Mall Gazette* judiciously observes, however, in reference to this decision, that

it does not appear from the report whether the technical or the substantial plea was the one admitted by the bench in the Warden's case. They may possibly, and perhaps rightly, have held that he did "everything that could be reasonably expected" of a head-master; but, if the technical plea were accepted as valid, the result is rather startling; for it would follow that, whether a head-master does all that can be reasonably expected of him or not in such a case, he is free from legal responsibility, or, in other words, that he might pack off home by train any boy known or suspected by him to be infected with a contagious disease, and that, from the moment of the boy's departure, neither his master nor any one else would be "in charge" of him or would be deemed, although they pay his fare for him, to have "aided or assisted him to travel".

#### OPIMUM-DUCKS.

IN Mr. Baber's recently published official report on the route of Mr. Grosvenor's mission through the great opium-growing districts of China, between S-u-chan and Yuman, it is said the whole district is given over, for hundreds of miles, to the cultivation of opium and ducks, called locally "opium-ducks", which frequently supplied Mr. Baber and his party with a meal, and do, he says, really appear to stupefy themselves by feeding on the narcotic vegetable. They allowed the travellers to walk openly up to within twenty yards of them, and even then they rose very languidly. The natives assert that the flesh of these birds is so impregnated with laudanum, as to exercise a soporific influence on the consumer. But a little more careful verification is necessary before a story of this kind is accepted in all its details.

#### ADULTERATED DRUGS.

FROM a large series of returns by public analysts, collected in the *Analyst* by Mr. Wigner, it appears that, out of the 403 samples purchased, 96 were adulterated; and yet, he says: Notwithstanding this state of things, I do not at present call to mind a single case in which the Pharmaceutical Society has, during the past year, instituted a prosecution for the sale of adulterated drugs. Can it be that the Pharmaceutical Society is fast degenerating into a trade protection society, although privileged and instituted to protect the public against the tricks and shortcomings of the trade?

#### MORTALITY OF IMBECILE CHILDREN.

THE Managers of the Metropolitan Asylum District have recently published in their minutes the report of Dr. Beach, the medical superintendent, upon the temporary asylum for imbecile children at Clapton, for the year 1877. This report contains some statistics of mortality which are not without interest. The asylum contained 331 patients on December 31st, 1876, and 350 on the last day of 1877; 57 patients were admitted, 23 were discharged, and 15 died, during the year. The average daily number resident was 343. Dr. Beach reports that "the death-rate, 3.8 per cent., is the lowest since the opening of the asylum". Excepting an outbreak of measles in November, which was confined to seven cases in that portion of the detached infirmary used for the reception of patients direct from the parishes, the institution seems to have been free from epidemic diseases. It is especially noted that no fresh case of ophthalmia occurred, "proving that the separate basin and towel system, when efficiently carried out, is an admirable protection against this disease". With regard to the rate of mortality, quoted by Dr. Beach as 3.8 per cent., it is evidently calculated upon the total number under treatment. This, however, is not so correct a basis for calculating the annual rate of mortality as the average daily number resident. The deaths recorded were equal to 4.39 per 1,000 of the average number resident; the rate among the male inmates being equal to 49.5, and among the females to 35.7 per 1,000, respectively. It is satisfactory to hear that the death-rate is lower than in any previous year since the asylum was opened. In order, however, to decide satisfactorily whether this is really a low or a high rate of mortality for imbecile children, some other standard for comparison is desirable. It becomes all the more desirable when we bear in mind

that, according to the English Life-Table, the annual rate of mortality among young persons aged between five and twenty years does not exceed 7.1 per 1,000, and that the rate of mortality at Clapton is just five times this *normal* rate among persons at similar ages. It may be noted that, in the two Metropolitan Asylums at Leavesden and Caterham, the rate of mortality in 1877 was equal to 89.1 per 1,000, against a *normal* rate of 27.7. The actual rate in these two asylums was, therefore, very little more than three times the *normal* rate. It becomes interesting to know whether imbecility is more fatal among children than among adults. Dr. Beach in his report does not give any table of the ages of the patients, although he gives the ages of the decedents. The omission is to be regretted, as it is impossible to calculate the true *normal* rate of mortality in a population without accurate knowledge of its age-constitution. With a view to comparison with the recorded death-rate in the Clapton Asylum, we will briefly refer to the mortality statistics of the Earlswood Asylum during the three years ending March 1878. Unfortunately, the statistics for this asylum refer to the years ending March, instead of the natural years ending December. The average annual number of inmates at Earlswood during the three years ending March last was 600; and the deaths in the three years were 85, or equal to an annual rate of 47.2 per 1,000. Dr. Graham, the Medical Superintendent at Earlswood, in his annual reports gives a table showing the ages of the Earlswood inmates, from which we have been able to deduce that, during the three years under notice, the number of idiot children aged between five and twenty years averaged 337, and that the deaths in the three years at these ages were 60, showing an annual death-rate equal to 59.3 per 1,000. Among the inmates aged over twenty years, the average annual death-rate did not exceed 31.6 per 1,000. These figures appear to support the supposition that idiocy has a greater influence upon the mortality of children than upon that of adults. The Earlswood Asylum mortality statistics for children during the three years ending March last show a higher death-rate than those for the Clapton Asylum during 1877. Dr. Beach, however, admits that his mortality statistics for that year were more favourable than those for previous years.

#### SUBCUTANEOUS EXTRA-ARTICULAR OSTEOTOMY FOR GENU VALGUM.

THE operation to which this name has been given was performed for the first time on Friday last, May 17th, at the East London Hospital for Children, by Mr. Reeves, in the presence of several foreign surgeons. Its object, which was thoroughly obtained, is to improve on the method of operating on cases of knock-knee devised and executed by Dr. A. Ogston of Aberdeen; and our object in calling attention to it at this early stage is to induce surgeons to give it that trial and preference which a less severe and equally efficient operation must claim. We give the substance of Mr. Reeves's observations before the operation. In Dr. Ogston's operation, the knee-joint is entered by the tenotome or scalpel, a fine saw is introduced along the knife-track, and the internal condyle is sawn off. This proceeding has now been done about thirty times *antisepsically*; and the results have been, on the whole, very encouraging; yet we have heard of a few cases in which synovitis, followed by severe constitutional disturbance and ending in ankylosis, has occurred. It was to avoid, if possible, these unnecessary complications, that Mr. Reeves thought of the extra-articular method. A scalpel, previously dipped in carbolic oil, was introduced obliquely just above the inner tuberosity, and the soft parts and periosteum were divided; by the side of the knife, a chisel, also dipped in carbolic oil, was introduced, and the internal condyle separated *as far as the cartilage only*; and, the chisel being then used as a lever, the condyle was prised inwards till it was felt to move moderately freely. The limb was then forcibly straightened by Mr. Caesar and Mr. Parker; a pad of lint dipped in carbolic oil was put over the small aperture; and a long splint, interrupted at the knee, and with a cross-piece at the foot to keep it steady, was adjusted to the straightened

lim As the condyle differs in shape and depth, it is of course necessary to be accurate in chiselling; and, to guide him, Mr. Reeves previously marked out with ink on the skin not only the contour of the condyle but also the direction of the chisel-cut. The greatest depth of the condyle was marked on the chisel, allowance being made for the thickness of the cartilage and of the soft parts; the chisel was then driven home till the mark on it nearly reached the skin. The condyle having been first penetrated in its greatest depth, the chisel was partially withdrawn; its direction was altered, first forwards, then backwards; and, with a few oblique touches, due allowance being made for the varying depths, the condyle was felt to be sufficiently loose, when the instrument was withdrawn and the knee straightened. The joint was not entered; no synovia escaped; and the feeling of resistance to the chisel was not at any time overcome. Had this been the case, the joint must have been opened. It might, *a priori*, be thought that the uncut cartilage, with perhaps some slight uncut bony bridges, would either interfere with the reduction of the deformity or would only yield after being broken. The result so far, in this case, does not confirm the objections, if they be serious objections. Experiment and experience must determine the matter in the case of adults; but in children, in whom the condyles are not completely ossified, and what bone there is in the young cancellous tissue is soft and pliable, these objections do not hold. But, even if the cartilage were to fracture, or even if the joint were entered—say purposely—with the chisel, the proceeding would not be so severe as if done with a saw. Another modification in this operation is noteworthy. It has been said that the internal condyle was separated. It is more correct to say that the greater part of it was almost separated; that is to say, that the chisel-cut did not extend to the intercondylar groove, but only to its inner side. The aim of this is to preserve some part of the inner condyle, which may grow, and thus obviate any possible future *genu extorsum* which may be the consequence of the increased growth of the external condyle. All these operations, which may be termed rapid as contradistinguished from the older methods of splinting and tenotomy, when necessary, are too young to admit of any dogmatic statements about them; but in the meantime we should adopt that method which is effectual and least risky. Delore's, Ogston's, Max Schede's, Annandale's and Macewen's, and the one just described, have all the same object with regard to this deformity; but the methods of executing it differ. One, by *brisement forcé*, separates the upper tibial epiphysis; another removes a wedge from the upper part of the tibia; another attacks the femur; and yet another removes a wedge from the internal condyle. Ogston's method and this agree in principle, but differ in execution and severity. The advantages of the extra-articular method seem to be, greater rapidity of execution, rendering it more strictly subcutaneous; much less damage to the bone, cartilage, and soft parts; no interference with the knee-joint; and, as the condyle is not completely separated, there is less likelihood of subsequent non-union and necrosis. Again, the resulting joint-surface will be more regular; and, by leaving a part of the condyle, the probability of a *genu extorsum* is much diminished. Then there should be no difficulty with the case. As soon as the condyle has become firmly attached in its new position, the stiffness will only be due to having kept the knee fixed for some weeks—say five—and not to ankylosis, which has to be overcome by frequent passive motions under anæsthetics. In the present case, it was endeavoured to make the section on the distal side of the line of junction of the epiphyseal cartilage. This is considered important with reference to the future growth of the inner side of the femur. The operation was not antiseptic in the Listerian sense; it was carried out in the same way as nineteen other osteotomies (five femora, ten tibiae, and four fibulae) by the same operator; and, as in these cases everything progressed as could be wished, no additional precaution was deemed necessary. Even this operation of minimum severity Mr. Reeves would at present confine to those cases of overgrowth of the internal condyle in which the older methods are not applicable or have failed; but, as soon as experience shall have taught that there is nothing to counterbalance its

many advantages, he would not hesitate to recommend and adopt it as the first means in the more severe cases of this deformity. Expensive and somewhat cumbersome apparatus become necessary after tenotomy, etc.; and they will not be needed in the case of surgically displaced condyle, the cause of the deformity—*i.e.*, the overgrown condyle—being put in proper position. It should, in conclusion, be stated that there has been no rise in pulse or temperature, and only such local pain as might naturally be expected.

#### THE CENSUS OF ADULTERATION.

SOME attempt has been made, on behalf of the Society of Public Analysts, to estimate, from voluntary returns, the work done during the past year in the way of detecting adulteration of food in Great Britain by the public analysts. The returns, although extensive, are incomplete. In reviewing them, Mr. Wigner observes that the first thing which strikes the eye is the vastly different proportions between the number of samples analysed in different districts. Thus, for instance, we find Somersetshire with 814 samples, Surrey with 455, Stafford with 667, and Cornwall with 28, while Norfolk figures with a grand total of 7 samples. In Mile End Old Town, where, according to the previous returns, 1 in 72 samples was adulterated, the authorities appear to consider that enough has been done; and therefore, during the past year, no samples at all were purchased. Hampstead previously showed 1 in every 59 to be adulterated, it now shows 7 in 62, which approaches a little more to the average proportion. At Hackney, where we had before 9 in 214, we now find (omitting 10 waters, all of which were condemned) 20 in 110; in the latter case, it is clear there has been some improvement in the mode of purchasing samples—perhaps instead of inspectors in uniform procuring them, unknown persons have been employed. Scotland, again, appears in a very unfavourable position, the number of samples analysed being only about 330; while Ireland, on the other hand, shows a very large total, mainly as the result of Dr. Cameron's 2,748 samples. Looking at the returns as a whole, they bear out the statements which have been often made, that the Act needs to be made compulsory, and that the samples should be purchased by unknown persons, and not by well-known officials. Viewing the matter in a broad light, it seems an almost incredible thing that, in a country like England, one-fifth of the samples purchased by officials are found to be adulterated within the meaning of the Act. Surely, if one-fifth are found adulterated when purchased in this way, the percentage of adulterated articles obtained by private purchasers must be very much larger.

#### EFFECTS OF MILITARY DRILL UPON THE HEART.

THE large amount of heart-disease in the British Army has attracted much attention from time to time, especially since Mr. Myers' prize essay was published. It was shown there, that after deducting the effects of alcohol, syphilis, Bright's disease, etc., there was still found a great proportion of heart-disease, which was caused by the uniform or by the drill service. Surgeon F. A. Davy, M.D., thinks that the form of drill in vogue is very injurious, and is the direct cause of much injury to the thoracic organs. It appears that in the "setting-up drill", it is essayed, so far as is practicable, to make the soldier fill his chest and then perform all movements with the chest fully distended with air, the consequences of which are a certain amount of emphysema with more or less embarrassment of the heart. The "stand-at-ease" is too brief for the heart to recover itself, and a condition of irritability or hypertrophy becomes established according to the nutritive powers of the individual. He says, "In the great majority of cases of heart-complaint invalidated (other than those brought about by rheumatic fever, Bright's disease, etc., of which the history is to hand) the early link in the pathological chain was forged in the drill-field. There has preceded the date of appearance at hospital a long period of uncomplained discomfort, often distress, consisting of breathlessness on slight exertion, headache, and 'beating'. Now exertion has become unbearable. A man who never knew he had a heart (an expression

many a soldier has used to me) becomes aware of his possession after a few months' dilating drill. He blames his recently donned pack and traps for his trouble; forgetting that as a civilian he could have carried them manfully across the country for ten or fifteen miles. Now, has this man been enlisted by mistake, or have we made him what he is?" This is a very serious question, and Dr. Davy seems to incline to the latter solution. If the drill be to blame—and it appears to be so—then the sooner it is reformed and brought more into accordance with our physiological knowledge the better.

#### WATER-SUPPLY IN RURAL DISTRICTS.

AT the meeting of the Congress on Water-Supply at the rooms of the Society of Arts on Tuesday, Mr. A. H. Brown, M.P., read a paper on the results of the recent parliamentary investigation into the state of the water-supply of the rural districts, in which he stated that the principal supply is from shallow wells and streams, which are polluted by every sort of abomination and matter of disgusting origin, and that such water was habitually used by the inhabitants for drinking and other purposes. The result of the discussion was that, by adequate means for securing good pure water, such as deep artesian wells and the utilisation of the rainfall, the water-supply of the rural districts might be completely revolutionised, and a great improvement effected in the public health.

#### PROPAGATION OF INFECTIOUS DISEASES BY SCHOOLS.

AT the annual meeting of the South Durham Medical Society, the report of the Subcommittee as to the propagation of infectious diseases by means of public schools was brought forward. It stated "that elementary day-schools are one of the chief means by which infectious diseases are spread. The fact that the Education Act makes no allowance for absence from sickness, and that the attendance of children has a direct bearing on the Government grant, causes direct pressure to be brought upon teachers and parents to have children at school, irrespective of their sanitary condition". The Society, therefore, recommended that the medical certificate system be adopted, and that children living in the same rooms as children so suffering shall not be allowed to return to the school without a medical certificate that they may safely do so; that a School Board medical officer be attached to, and paid by, every school authority; and that all the school authorities in the kingdom be asked to unite with the Society in memorialising the Government on the subject.

#### POISONOUS VIOLET-POWDER.

AN illustration of the injurious nature of the violet-powder commonly vended reaches us from Goole. On April 18th, Mr. G. E. East attended the wife of a sailor in her confinement; and four days afterwards, was asked to account for a rash which appeared on the infant's skin. The rash resembled roseola, and was pretty general upon the body, but most apparent upon the flexures of the limbs and round the throat. Fuller's earth was substituted for the violet-powder that had been used in the dressing of the child, and the rash disappeared in two days. Some of the violet-powder was examined chemically and microscopically by Dr. Parsons, the Medical Officer of Health, who found that it was free from arsenic, but instead of being composed, as such an article should be, of starch or such like bland substance, it consisted almost entirely of powdered hydrated sulphate of lime, probably scented with a littleorris-root. The use of this substance for such a purpose Dr. Parsons strongly condemned; the only advantage lying in the deodorising qualities of sulphate of lime. The *Sanitary Record* recently confirmed the statement that an epidemic had been caused by the use of this deleterious violet-powder, and suggests that steps should be taken to prevent its sale. In that opinion we fully concur.

DR. VON DE HOFF has retired from the Professorship which he has held for many years in the University of Munich.

## SCOTLAND.

THE temperature in most districts has fallen considerably, and heavy showers of hail and snow, with high winds, have been general. In Fife, the rivers were swollen by torrents of rain; and the Grampian and Ochil ranges were coated with snow, which, however, soon melted.

A SAD event has occurred at Lochinver, Sutherlandshire, in the suicide, by prussic acid, of Dr. James Bruce, a young unmarried man, who has acted as medical officer to the Parochial Board there for the last two years. He left a note for his father, saying that he had been in a desponding state of mind for some time.

THE Secretary of State for India has signified his approval of the arrangements made by the Aberdeen University Court for the supervision, in the house of one of the professors, of any selected candidates for the Indian Civil Service who may attend that University during their time of probation.

A WOMAN at Bellshill is supposed to have been poisoned, by phosphorus, administered in a glass of water, by her son, a collier, about seventeen years of age. A small bottle of phosphorus was found in the house, said to have been used in chemical experiments by an older son. Little hopes are entertained of her recovery.

#### THE REGISTRAR-GENERAL'S QUARTERLY RETURNS.

WE learn from these that, during the first quarter of the present year, the number of births registered in Scotland was 31,226; of deaths, 20,320; and of marriages, 6,068. The number of the population, estimated to the middle of 1878, is 3,593,929. The birth-rate has been 3.48 per cent., the average being 3.49 per cent. Of these, 8.46 per cent. were illegitimate. The death-rate has been lower than any recorded for this quarter since 1863, being an annual proportion of 26 to every 10,000 of estimated population. In England, the death-rate during the quarter has been computed at 26 for every 10,000 inhabitants, the average being 240. In the rural districts, especially in the islands of Scotland, the diminution of mortality has been very marked. Of the principal towns, Paisley has shown the highest (328) and Perth the lowest (206) death-rate. In Dundee, the death-rate for this quarter of 1877 and 1878 was exactly the same. The marriage-rate has hardly come up to the average rate of the last ten years. Marriages took place at the rate of 83 to 10,000 inhabitants in the large towns; being most numerous in Paisley, 104 to 10,000 inhabitants.

## IRELAND.

IN accordance with a resolution passed by the Belfast Board of Guardians at a late meeting, the Local Government Board have directed Dr. Roughan to hold a sworn investigation into the mode of conveying deceased paupers to the place of interment.

#### LIMERICK LUNATIC ASYLUM.

AT a meeting of the governors of this institution, held on the 14th instant, an official communication was received, increasing the salary of Dr. Courtney, resident medical superintendent, to £500 per annum under the recent regulations.

#### SMALL-POX.

AT a meeting of the Guardians of the Rathdown Union last week, it was reported that eleven small-pox patients had been received into the infirmary, two of which had proved fatal. The Chairman drew attention to the necessity of providing burial in cases of death from the disease occurring in the workhouse, and referred to a case in which the body of one of the patients had remained waiting for the coming of the friends for thirty-six hours, and a pauper inmate, who had voluntarily attended the deceased in lifting the body into a coffin, had contracted the disease, and had since died of it.

## ROYAL COLLEGE OF SURGEONS OF IRELAND.

MR. R. BUTCHER has intimated his intention of not seeking re-election on the Council of the College. The following Fellows are, we hear, candidates for seats on the Council, in addition to the existing members who are eligible for re-election: Messrs. H. Gray, Croly, Elliott, Jacob, Madden, Roe, and Thornley Stoker.

## RATHFARNHAM AND WHITECHURCH DISPENSARY DISTRICT.

DR. HENRY CROLY having resigned, an election for medical officer to the district will take place on the 3rd proximo. The emoluments of the appointment are £125 *per annum* as medical officer and £30 as sanitary officer, with registration and vaccination fees. It is considered probable that Dr. Croly will be succeeded by his son, Dr. Albert Croly.

## TYPHOID FEVER IN COOKSTOWN.

DR. GRAVES, sanitary officer, at a meeting of the Board of Guardians, held last Saturday, complained of the sanitary condition of certain houses in this town in which typhoid fever had broken out. The cause he attributed to defective sewerage, want of proper accommodation, and the existence of open cesspools. An order has been made by the Board to have these premises put in proper order immediately.

## HEALTH OF DUBLIN.

THE deaths from zymotic diseases registered in the Dublin district, during the week ended Saturday last, numbered 57, being 28 over the average for the twentieth week of the year of the last ten years. Of this number, 21 deaths are due to small-pox, the registered deaths from which disease, during the last six weeks, have been respectively 15, 9, 21, 17, 12, and 21. The number of cases of this disease under treatment in the Dublin hospitals (including the temporary hospitals in connection with the Union Workhouses) on Saturday last was 270, against 254 on the preceding Saturday; 106 cases were admitted during the week, being 16 over the number in the previous week; 73 patients were discharged as cured, and 16 died.

## LIMERICK BOARD OF GUARDIANS.

DR. O'CONNOR, one of the visiting medical officers of the Limerick Workhouse, having lately resigned, an election for his successor took place on the 8th instant, when Dr. James Meehan was selected from among several applicants for the post. The Local Government Board, however, last week communicated with the guardians, and declined to sanction the appointment—for the reason that, some time ago, Dr. Meehan had been sentenced to twelve months' imprisonment for his share in the frauds on the New York Insurance Company, when he was charged with having certified for parties who had not been examined by him. His name was struck off the *Medical Register*, but was subsequently restored by the General Medical Council. The Local Government Board remark that, by this act of the Council, Dr. Meehan was merely enabled to pursue his practice as a qualified medical man, and it was for those who chose to place so much confidence in him as to seek his services as medical adviser to use their own discretion in doing so; but that this was a totally different matter from the Board of Guardians and the Local Government Board appointing and permitting Dr. Meehan to have charge of many hundred of patients daily, who have no voice in choosing their own medical attendant, and who might most reasonably be disposed to place no confidence in Dr. Meehan; also that, by Section xxii of the 6th and 7th Vict., cap. 92, no person convicted of fraud is qualified to act as guardian of the poor, and that such objection seems to apply with peculiar force to paid officers of high position and trust in the workhouse; and the disqualification would probably have been extended to those officers, if it had appeared likely or even possible they would be appointed. The guardians, by a large majority, expressed their belief in Dr. Meehan's innocence, and requested the Local Government Board not to enforce their order, but to wait an inquiry which was shortly to be held in Parliament into the justice of Dr. Meehan's case.

METROPOLITAN COUNTIES BRANCH:  
SPECIAL GENERAL MEETING.

A SPECIAL General Meeting of this Branch was held at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Wednesday, May 15th, at 4 P.M.: S. W. SIBLEY, Esq., President, in the Chair.

*New By-Laws.*—An amended code of by-laws was submitted to the Branch by the Council, and was approved.

## AMENDMENT OF THE MEDICAL ACTS.

THE CHAIRMAN: The real business of this afternoon is the consideration of the Medical Bills. You are all aware that there are at the present time before Parliament two Bills—that introduced by the Lord President, and that introduced by Dr. Lush. Dr. Lush's, I believe, has the priority in point of time; but I put the Lord President's first, as that which is probably engaging the most extensive amount of attention. These Bills deal with a number of most important questions—questions which the Association has very frequently discussed; and, in order that the matter may be more easily discussed, the Council, as you are aware, have sketched out a few resolutions, which I shall have the honour to propose to you, affirming a number of the great principles that the Association has hitherto approved. Four of these resolutions affirm great principles; the fifth opens the question how these principles are to be applied. The first resolution is:

"That an amendment of the law is required in order to prevent the assumption of medical titles by unqualified persons; and that this Branch regards with satisfaction the proposals to amend Section xl of the Medical Act for this purpose."

As regards that resolution, I think I shall have the support of the whole meeting, when I say that we have long felt that Section xl of the Medical Act was totally inadequate to define the condition of qualified practitioners, that it failed to prevent the unqualified from passing themselves off as qualified; that, in fact, it was totally inoperative. The only apology, I think, that can be made for Section xl of the whole Act is that it was a matter of compromise, and I believe that it was the only clause that could have passed the Houses of Parliament at that time; but, being totally inadequate, it long ago became necessary to revise it. That law is revised, as you are aware, in the Lord President's Bill, and even in still more stringent, and perhaps more definite, language in Dr. Lush's Bill. The second resolution is:

"That every person placed on the *Medical Register* should have a qualification in both Medicine and Surgery, so that the fact of registration may be a guarantee to the public that the individual possesses at least a minimum (and at the same time sufficient) qualification to practise all branches of the medical art; and that, in order to insure this, it is desirable that the formation of conjoint examining boards should be made compulsory in each division of the kingdom."

Now, that is a point which is not included in either the Lord President's Bill or in Dr. Lush's; Dr. Lush's Bill treating only of two matters, the revision of Section xl and the admission of foreign degrees. The Association, I think, has always pronounced an opinion in favour of the conjoint scheme. It has been felt that it was an anomaly not to be tolerated, that a person with a qualification to practise medicine should be allowed to practise surgery, or *vice versa*; and, therefore, it has become with them a matter essential for the public interest as well as for the profession, that every member who enters the profession and becomes a registered practitioner should have a double qualification. The simplest way to carry this out is, no doubt, by a conjoint scheme. The conjoint scheme, as you are aware, has excited a good deal of opposition, especially in the sister kingdoms; but in this part of the kingdom the corporate bodies and the profession at large have pronounced, I think, emphatically in its favour, and, therefore, I have little doubt that this Branch will pronounce a similar opinion. The third resolution is in the following form:

"That it is desirable that the Medical Council should have a disciplinary power over the holders of colonial and foreign diplomas and degrees of the same kind as the medical corporate bodies possess with regard to their fellows and members."

In the Duke of Richmond's Bill, and also in Dr. Lush's Bill, there is a provision made for the placing upon the *Register* those who possess foreign and colonial degrees; but our attention has been called to the fact that members so placed on the *Register* would not belong to any of the great corporations, and, therefore, no body would exercise any power of control over their actions. If a person, for instance, were admitted with a foreign or colonial degree and placed on the *Register*,

he might be guilty of very great improprieties short of criminal offences—which would bring him under the discipline of the Medical Council—and still there would be no power of striking his name off the *Register*. It is, therefore, proposed that a clause should be inserted in the Act which would give the Medical Council a similar power to that which the College of Surgeons and the College of Physicians possess over their members, so that they might be held in some form of check and control from irregularities of practice. That is an omission in the Duke of Richmond's Medical Bill. The fourth resolution is:

"That it is desirable that the voice of the profession should be expressed in the Council by means of direct representation."

That is a great principle, upon which, I think, most of us feel strongly. We feel that the profession should have some, if not an important, place in the management of their own affairs. At present, the Medical Council simply represents a number of important bodies; it does not represent the profession at large. It is felt that, if the profession itself exercised a direct influence in the Council, the cause of medical reform might be assisted, various inequalities might be removed, and the want of perfect operation of the law remedied. Moreover, the present Medical Council very inadequately represents the voice even of the educational bodies. For instance, in England, four members represent the universities, and three the corporate bodies. Now, the universities, of which I would speak with the greatest reverence and respect, are not essentially medical bodies. The older universities contain only a very small number of medical graduates; but the London University contains a much larger number; while the Royal College of Surgeons, which contains the bulk of the profession; the College of Physicians, which contains a very fair number; and the Apothecaries' Company, which also contains a very considerable number, have only three representatives. I think it would be a great improvement in many points of view that the profession should exercise a direct control. I know that this is a matter which will raise discussion, and probably some persons will be ready to advocate "indirect" representation; but I simply content myself with putting forward this resolution, and advocate direct representation. Then comes the fifth resolution. This touches, as you will see, not upon any essential matter that has gone before, but as to how far we shall be guided in our advocacy of, or opposition to, the Bills before us. It is:

"That it is not expedient to oppose the progress of any Bill which may contain satisfactory provisions for—1. The establishment of the conjoint examining boards; 2. The amendment of the Penal Section of the Medical Act; 3. The registration, under proper supervision, of foreign and colonial degrees and diplomas, on account of its not including provision for the direct representation of the profession on the Medical Council."

I feel that there, again, a good deal of difference of opinion will be excited. The question is, if we can get these most important matters settled, are we justified in opposing the Lord President's Bill, or in opposing both the Bills, because they do not include direct representation? Well, I think that the answer will hinge upon this matter. If the Bill pass, what will be the hope of getting direct representation at a future time? Many feel that, when once these great defects in the old Medical Act are remedied, we shall have little or no hope of a further amendment of the law to secure direct representation. But I think it may be quite possible that, supposing some of these different inequalities are remedied, a further Bill may be brought before Parliament, and we may obtain our direct representation at a future time. I will not delay you any longer, but simply propose these resolutions.

MR. NELSON HARDY: We shall probably all agree in the desirability of obtaining such amendments of the law as are indicated in the first four resolutions which you have placed before us; and, if I thought it at all likely that we should also be unanimous as regards the fifth, I should content myself with simply seconding the motion. As it is, what I say will have principal reference to that fifth resolution; but, first, let me say a word or two about the fourth. I admit at once that there has been for years a very strong feeling of dissatisfaction with the constitution of the General Medical Council; that it is believed to look after the interests of the examining bodies more than the general interests of the profession or the public; and that the great remedy for this state of affairs has been held to be direct representation. But I confess I am not quite convinced by the arguments advanced in its favour, that direct has such great advantages over indirect representation that it alone should be urged as the remedy. Take our own Association, for example. In this Branch, we have, it is true, direct representation on our governing body, the Council; but, in the general body of the Association, we are governed by the Committee of Council, which is an example, not of direct, but of indirect representation, and I for one am not prepared to say that their government is so utterly bad, that we ought at once to agitate for direct representation in it.

There is another consideration with regard to this which I should like to mention. It seems to me that the Bill of the Lord President, which provides for the registration of midwives and dentists by the Medical Council, has introduced a new element into the discussion, and rendered it necessary for us to reconsider our position; for it is undeniable that, if a medical man, by paying his registration fee, acquire a right to vote, a woman, by paying her registration fee as a midwife, will also acquire a vote; and, as it is calculated that eleven thousand five hundred midwives would register, they would, of course, demand a representative on the Council, both as a right and in order to improve its composition. The dentists, in the same way, many of whom would at first be simply chemists, would naturally think that the Medical Council would be much improved by having a knight of the pestle and mortar taking a seat on its board. The principal subject, however, which we have to consider to-day is the fifth resolution. You will notice that, while in the other resolutions it is said to be desirable to get certain specified changes, in this fifth resolution the question is whether it is not expedient to accept some of these desirable things, if you cannot get them all; whether, in fact, half a loaf is not better than no bread. On a subject like this, we may well ask what is the expressed opinion of the Association; and I would remind you on this point that, at the past annual meeting, a resolution was passed by a large majority, directing the Medical Reform Committee to take such a reasonable course as is indicated in this fifth resolution: to give up for a little time grasping at shadows, and devote their energies to securing such solid benefits as were well within their reach. I am well aware that the extraordinary doctrine has been put forth apparently on authority, that the committee appointed by that vote of the Association conceived itself at liberty to disregard the wishes of the Association, because, forsooth, there were but, as some say, thirty-five, and as others more probably say, one hundred, persons present, though only twenty-five were needed to make a quorum; or because notice had not been given when no notice was necessary; or because the instructions given them did not coincide with their own views; or because it was the fog-end of the meeting, or for some other reason. But that is a doctrine which, if it prove anything, proves rather too much. If the vote were invalid for want of greater numbers being present, the Medical Reform Committee of the Association has no existence. If valid, they are in open and avowed rebellion against the legally expressed will of the Association, from which there is no appeal; no, not to the Committee of Council itself. If this be so, look at the position in which the Medical Reform Committee have placed themselves and us. Not only have they not done what they were especially directed to do, but they have actually gone out of their way to oppose the expressed wishes of the Association. They could not even prepare a petition for the House of Lords against the Government Bill without giving a thrust also at any other Bill, such as Dr. Lush's, which corresponds very closely to what they had been directed to prepare. Defeated in the Association, they, using its name, appeal by *pétition* to outsiders, and tell the voters, both within and without the Association, how it is imperatively required that they shall vote. It is most humiliating to think of the position of insignificance to which our great association has been reduced, as regards its influence, by the Medical Reform Committee. Just as, eight years ago, it could do nothing but obstruct the passing of Lord Ripon's Bill, thereby disgusting and driving from the Association such men as Acland, Stokes, Paget, and Rumsey, so now, when there are two fresh Medical Bills before Parliament, our Association is, if the Medical Reform Committee have its way, to confine itself to a barren protest against both, and to be utterly impotent for good as regards either; while all other interested bodies—the Medical Council, the Colleges of Physicians and Surgeons, and those defence associations which, in comparison with ours, are but of yesterday—are suggesting improvements to which they find the Duke ever ready to listen, we are to take up the position of Irish obstructionists, oppose all useful legislation that does not give us our hobby. That is evidently not the course which the Committee of our Council who drew up these resolutions recommended us to adopt, and I am curious to hear what arguments can be brought forward in its favour by reasonable men. It will be useless for anyone, no matter how authoritatively he may speak, to tell this Branch how it is imperatively required that we should vote. There are, as I have said, two Medical Bills now before Parliament. One is the Government Bill, which, as originally drafted, contained clauses rendering compulsory the establishment of conjoint examining boards. These have been withdrawn at the suggestion of the Scotch bodies; but it only needs sufficient pressure from without, such pressure as our Association could exert, to get them resuscitated. The other Bill, which is down for second reading to-night, is identical in purpose with that which the Association directed its Committee to prepare. The resolutions now placed before you give us

the opportunity of declining to be responsible for any further obstruction of medical reform. They will, if carried, enable this important Branch of our Association to exercise its legitimate influence upon the medical legislation of the country. On all these grounds, I have much pleasure in seconding the resolutions.

Dr. WATERS (Chester): Though not a member of the Branch, Mr. President, I am bound, as chairman of the Committee to which the gentleman who has just sat down has referred, to say a few words in reply. The gentleman who has seconded this resolution, in a very carefully and sharply worded speech, has indulged himself in a long and exhaustive tirade against the conduct of gentlemen, who, whatever else they have done, must be admitted to have done their best for the Association. Whatever may have been their conduct, they are honourable men; and for any member of this Branch to arraign a body of gentlemen without bringing them all here to defend themselves, is to me one of the most unexampled occurrences that I have ever heard of in connection with the British Medical Association. I am Chairman of the Medical Reform Committee of the British Medical Association. I will not go into all that the Association has done for forty-six years, but the Medical Act of 1858 was certainly passed through its efforts. By that Act, a General Medical Council was created, to whose management medical reform was confided. There was an implied promise before the passing of that Act, that the profession in this country should be directly represented in the General Medical Council, as soon as there was a *Register* of the profession. Nine years passed, and nothing was done. One of the old members of the Medical Reform Committee, Mr. Husband of York, then proposed in council that this question of direct representation of the profession should be brought before the Association; and at the meeting in Dublin, with only two dissentients, it was decided that there should be direct representation of the profession in the General Medical Council. The Committee appointed waited on the General Medical Council, and urged the Council to grant the prayer of the profession. Well, it was not granted. I am not going into it, because all that has been before the Association. The Government brought in a Bill; the Government solicited the opinion of the General Medical Council as to whether there should be any change in its composition. That requirement was not, to the best of my knowledge, acted upon. The Government were told by the Direct Representation Committee that any Bill not making provision for direct representation would be opposed by the Committee. The Bill came before the Lords. The question was mooted there. It came before the Commons; and the Bill was withdrawn. Now, had the General Medical Council responded in the slightest degree to the desire of the profession that there should be some modification of its composition, the Direct Representation Committee would gladly have welcomed any such assurance. The question of allowing the Government Bill to be withdrawn when a Special Committee of the House of Commons was offered, was considered by the Committee; and I may say this, that in communication with members of Parliament of the highest distinction, I was assured that if the Bill passed, then the question of any further medical Bill would not be entertained by the House of Commons. They told me that, if any Bill passes, the House will not entertain that subject again for some years. The question of direct representation is not regarded as a minor one by the profession, and therefore it was that the Direct Representation Committee held to its colours. On what instructions did that Committee act? There had been a meeting at Dublin, where the vote might be said to have been unanimous. There were two dissentients, but one of those dissentients is now a most active and influential member of the very Committee of which I am chairman. I refer to Dr. Stewart. At Oxford, the following year, the same thing was affirmed by the Association. At Leeds, at the next meeting, the same thing occurred. In July 1868, the Metropolitan Counties Branch had a special meeting, and decided that direct representation on the General Medical Council was to be regarded as a *sine quâ non* in any measure of medical reform. It was acting on the absolute instructions of the Association at three of its meetings, and at another meeting which was held in May 1870, specially to consider the question of the Medical Acts, and on an instruction passed unanimously by the Metropolitan Counties Branch, that the Direct Representation Committee declined to accept the Bill of the Marquis of Ripon. But, Sir, I may say that though we did our best not to let that Bill pass without the representation of the profession in the General Medical Council, it was not due to us alone that it was rejected. The members of the Scotch corporations and the members of the Irish corporations were then active in their efforts to shelve the Bill. I believe myself that the probability is that even without the aid of the Association, those corporations would have succeeded in shelving the Bill; as I believe that the present Bill of the Duke of Richmond, even though it accords the conjoint

scheme, will be shelved through the action of the Scotch and the Irish corporations. I believe that the Duke of Richmond's Bill, supposing it to concede the conjoint scheme, has no greater chance of being passed this year than Lord Ripon's Bill had in 1870; and I am expressing not merely my own opinion, but the opinion of members of the House of Commons. A great deal has been said about the improper action of the Medical Reform Committee. The Medical Reform Committee has brought forward its reports year after year at the annual meetings of the Association. In like manner, a report was submitted at the meeting at Manchester, and that report was acceptable to the meeting, when it was proposed to add a rider to the effect that in case it was found that the great features of medical reform could not be included in a Bill, then the enforcement of the penal clause should be made the special subject of a Bill. It was alternative. The proposer of the resolution is present, and he will bear me out when I state that it was put as an alternative measure—that if the Bill of the Association in all its grand features could not be carried, or no movement was likely to prove effectual with regard to it, then the smaller Bill, with its distinct object, should be proceeded with. Having laboured year after year at the great task which I had in view, the removal of a great public hardship, I resigned. The Medical Reform Committee, notwithstanding my resignation, and the resignation of Mr. Husband, who was on the original Medical Reform Committee before the passing of the Act of 1858,—

Mr. HARDY: I would call your attention to the exact resolutions passed. You have not exactly stated them.

Mr. HART: I think Dr. Waters is correct in the manner in which he puts it. The question I asked the meeting was whether, supposing the large features of reform did not come forward, would it not be desirable that the practical question should be urged.

Dr. WATERS: I would say I am not going to be governed by an incomplete report of what occurred. I say that what I state with regard to Mr. Hart's movement upon that occasion is perfectly correct, and that Mr. Hart was extremely sorry that any member of the Committee thought it right to resign on that occasion. The Committee remained none the less efficient without me. Well, that Committee met, and the question was, what was to be done in regard to medical reform; how were they loyally to act as regarded the resolution passed at Manchester; and they decided that they would consult with different members of Parliament, and see what it was possible to do. They did consult with members of Parliament, and the members of Parliament recommended them to go in for the broad features of their Bill, and not to go in for the small Bill alone. They also said that it was a matter of extreme difficulty for private members to carry any measure of great public importance; that it would be certain to evoke opposition. Acting under that guidance, the Medical Reform Committee were not going to bring in any Bill at all this year, but they were going to apply, through one of the most distinguished members of the House of Commons, for a Committee of the House to go into the whole question of medical reform; and in that Committee the questions mooted by different men, by different parties, by different corporations, would have been ventilated, and on the report of that Committee a Bill would be founded in the following year. This distinguished member, acting with other members of the House of Commons, having suggested this course, and, it being brought forward at a regular meeting of the Committee, that course was approved of, because it promised medical reform not on one basis only, but upon the basis of the investigation of a Special Committee, which would sit this year and come to certain general conclusions, which conclusions in the following session would have been embodied in a Bill which would have been discussed *pro forma*, and we should have had something that would, I hoped, have satisfied the profession. Now, I believe that the Medical Reform Committee, in adopting that course, acted wisely; that it would have been a wild measure to attempt to press forward a Bill in opposition to the Government, and that it was a wise course to ask for this Committee of the House of Commons, which we were assured would be granted. That has been the action of the Committee. Well, then information was obtained that the Government had its own Bill. ["What date?"] I cannot give you the exact date now, but it was some time before the introduction of the Bill. Lord Sandon informed a member of the House of Commons that the Government had a Bill drafted, and that on the face of it it was of no use attempting to bring in a Bill of our own; in fact, the members to whom I refer were desirous to leave the course clear for the Government, as the Medical Reform Committee had for two years past left the course clear for the General Medical Council to do what it could in bringing about a voluntary junction of the different authorities. We had nothing further to do until the Bill of the present Government came in. We then waited upon the Government, and laid before them the importance of

the conjoint scheme and of direct representation of the profession. [Dr. HART VINEN: "What date was that?"] That was as soon as it was found that the Government Bill did not contain either of those provisions—that it was permissive as regarded the conjoint scheme and that no provision was made for direct representation. The Committee waited upon the Government, and I may venture to say that at this moment the direct representation has, I believe, as good a chance of being accepted by the legislature as the conjoint scheme. I am sorry to take up so much of your time, but the Medical Reform Committee has, I believe, done its best. We have been acting on the instructions to which the Association has adhered for years; we have been acting on the instructions of the Metropolitan Counties Branch in times gone by; we are at this moment supported in our demands by the Irish Medical Association; and, at a meeting in Liverpool the other day, specially summoned to consider the Duke's Bill—a much more numerous meeting than we have here to-day—it was unanimously resolved not to accept the Bill unless it provided for the compulsory establishment of the conjoint scheme and for the direct representation of the profession.

Dr. QUAIN: Both or either?

Dr. WATERS: Both. This Branch has done the same thing, and here you are to-day aiming at rescinding action to which you have adhered during the whole of your previous existence. At no annual meetings of the British Medical Association have these points ever been questioned; but now a gentleman makes a very good speech, and wants the Metropolitan Counties Branch to sink into the slough of despond or the mire of inconsistency. I have nothing more to say, as far as I am concerned; but I would say that, if a meeting were held in Edinburgh, with Sir Robert Christison in the chair, and Dr. Andrew Wood and other gentlemen present, and if it was there determined that, if direct representation were conceded, the conjoint scheme could be made a secondary matter, that resolution would in all probability have as great a chance of being carried as this resolution here to-day. But the Association could not possibly be bound in its action by the decision of any Branch. The Committees of the Association hold office under the Association, not from any Branch.

Dr. HART VINEN: Having been a member of the medical profession for more than thirty years, and having from my earliest recollection heard the question of "medical reform" agitated constantly, I may say that I have never yet understood precisely what that formula means, and I do not know now. I am quite certain that every member of the Association gives every possible credit to those gentlemen who have, from time to time, agitated in favour of medical reform, whatever it may be; but, as far as I am concerned, I am very anxious indeed that all these four practically beneficial clauses should be passed, and that they should not be sacrificed merely to a fanciful or sentimental perseverance in securing provision for direct representation of the profession on the Medical Council. I think we ought to be satisfied with half a loaf if we cannot get the whole.

Dr. STEWART: I believe that this is one of the most important subjects that can be brought before the Association, or before any Branch of it; and on this, as on former occasions during the last few years, I see that this Branch seems to take very little interest in this most important question. I look back twenty-five years, and then the medical reform meetings of the Branch were the most numerously attended of all. We used to have them so large there was not room in the place of meeting. That shows that, at one time at least, this Branch had some appreciation of the importance of the subject, and had some intelligent notion of what it meant. I remember that my old friend Dr. Roger of Paris came over, in 1846, appointed by the Minister of Public Instruction, to inquire into the medical organisation of England; and, as a very special friend, he came to me, thinking I could put him in the way of getting some information about it. "Oh, my dear fellow," I said, "it is disorganisation we rejoice in here; there is no such thing as organisation; it is utter disorganisation; there is no order of any kind, and I do not know who can give you an idea of what is really the prevalent state of matters in England. Certainly there is no symmetry, or anything like consistency, in any parts of our system, if you can call the absence of system a system." That was the state of matters which the Association at that time was endeavouring to reform, and it was they who did it. We might have waited till now, and our corporations, of whom we hear so much, would not have moved a finger, content to rejoice in their own large pecuniary returns, the larger the better, even though they degraded themselves in many cases, as I know, by underbidding other corporations and colleges who were more conscientious in their mode of examination. That was the state of matters, and it would have continued till now if it had not been for this Association. It was this Association that began the whole thing, and here lies the strength of my position. They showed that they felt it was a disgrace to the pro-

fession in this country that matters should continue as they were, and so they began their medical reform work almost contemporaneously with the existence of the Association, as Dr. Waters has already told us. It was a grand work. They laboured at it might and main, year after year. This forenoon, I was looking up the report of a deputation that went to Lord Palmerston, when Lord Palmerston said that the state of the profession, as regarded organisation, was deplorable. I think I counted up thirty Members of Parliament, headed by Mr. Macaulay, and including other distinguished names, who waited upon Lord Palmerston upon this same subject; and now we are asked by Dr. Quain and Dr. Vinen: "What is the meaning of medical reform?"

Dr. QUAIN: *Present medical reform.*

Dr. STEWART: The whole subject was started, carried on, and completed by this Association, so far as it has been completed; and now the very people who rendered the greatest services on this great question are the only people to be excluded from any voice. I say that it is grossly, scandalously unjust. It is like the old boroughmongering, where a pauper voter or two met together to elect a Member of Parliament for a great constituency, while thousands of others were left outside in the cold; and now we are told that these Councils or Senates scattered throughout the kingdom, and not numbering above four hundred or five hundred men in all, are the only medical men who have a right to express any opinion in regard to the shaping of the whole future of the profession. In any discussions on the subject with people who have taken an interest in it, I have found that they are apt to depreciate the work of the Medical Council, and to say that it is a very small work, that their sphere is really an exceedingly narrow one, and I have been asked: "What have you to do with that which is only a technical matter that only those few experts who belong to the colleges or corporations can understand?" I utterly repudiate the notion. The Medical Council has in its hands the whole future of the medical profession as regards its education, training, and so on. Now I say that, if you look over the old Bills introduced by the Committee of this Association, you will see that, from the beginning, they showed the most exact appreciation of what was wanted by the profession for the complete training of the new generation of medical men. There is nothing better now-a-day. Now this proves to me, in the first place, that we may give an affirmative answer to the questions (1), are the medical profession entitled, and (2), if they are entitled, are they qualified, to have a voice in the management of their own affairs? It is the management of their own affairs, of all that concerns them in the training of students, in the systems of education, in the examination, in the discipline of the profession, in the removal from the *Register* if they have behaved wrongly, that is expressly in the hands of the Medical Council. Why, I say, should not a body of highly educated medical men—because, thanks to the efforts made in the last thirty or forty years, the style of education is very much widened—have a right to be heard in these most important affairs as regards their own profession? That is the ground on which I base the whole thing. They have a right to it. As regards this matter of direct or indirect representation, indirect representation simply means that a man is returned for a particular body by a large number of people. But of course the potential people are those who are the administrators; they are, after all, the people who have the real voice in the matter; and, in all matters that concern the interests of that body, they will take the line which seems to them most suitable, independent altogether of the general body, even though, as Mr. Hardy thought right, the representatives should be returned by the whole body of the College of Surgeons, for instance. Supposing in any case there comes a question, such as one between the conjoint scheme and the pecuniary interests of the College, do you think that any body of Fellows of the College who had a vote in these matters would give a vote which they thought would directly tend to diminish, perhaps largely, the revenues of the College? And yet that might be the only way in which the public interests could be consulted. The conjoint scheme is, after all, one of the great questions we have to decide; but if I, as a Fellow of the College of Physicians, for instance, thought that the conjoint scheme would pecuniarily ruin the body to which I belong, do you think I would be quite free to say, "I think it is quite right and proper it should be carried, because it is for the public interest"? No; the *esprit de corps* would carry it. But, if you send men who are independent of all bodies, then they will only consider what is for the good of the public. There are as good men outside the Medical Council as ever have been or will be in it; and many of those men are able to throw light upon the problems that the Medical Council has to discuss, and would greatly strengthen the hands of those who work to overcome obstruction within the Medical Council and to help on that which we believe to be for the interests of the profession and for the public in general. These are some of my reasons for saying I think we should be very much the better for

having an infusion of new blood—an infusion, above all, of men who will be perfectly free and untrammelled. It is said, "You have the Government nominees". Far be it from me to say a single word against the Government nominees—a most noble, distinguished, and admirable class of men; but that is a chance. They are probably the nominees of one man. I suppose it is very likely that many of them were the nominees of Mr. Simon when he was at the Privy Council. I say that is not a decent and proper way in which the whole body of twenty thousand medical men in the kingdom should be content to let matters rest. They should have the acknowledged right of having a say, at least to the number of one-fourth, in managing their own affairs. Now, sir, we are told that the government of this Association is partly indirect. I say there is nothing indirect in it. The Council is composed of men sent up directly from every Branch; the Committee of Council consists of men elected out of that Council. It is as direct as can be. The Council cannot select one single man who has not been sent up. It is a Committee of the Council. The Council simply delegate to these men their powers to carry on the work of the Association. If my observations have been at all to the point, if I have succeeded in making out a very strong case for the right of the general body of the profession to legislate for itself, and if I have at all succeeded in showing that there are ways in which an infusion of men directly sent up by the medical profession to the Medical Council would be useful, I think you will be prepared for my dissenting very strongly from that fifth resolution. Therefore I wish to propose, as an amendment, that the whole of these resolutions be adopted, with the exception of the fifth; and I hope we shall prove ourselves to be in accordance with our former traditions, and with the general feeling and wish of the Association of which we are members, as shown by the canvass which Dr. Waters has made, the result of which, I believe, is 247 against, 5,000 in favour of, the conjoint scheme and direct representation.

Dr. WATERS: There were about 120 "Noes" to direct representation; some of those give "Yes" to the conjoint scheme. There are 49 absolute "Noes" to both questions. There are about 270 "Noes" to the conjoint scheme. So we may say there are 120 against direct representation, 270 against the conjoint scheme, and all the rest affirmative. The affirmatives amount to something more than 5,000 for direct representation, and about 4,800 for the conjoint scheme. I am afraid that those who are opposed to the conjoint scheme are very powerful in Parliament, that they are really not on the Reform Committee, and that they are obstructive. I have seen some Irish members to-day, and there is a strong feeling that if the Bill include the conjoint scheme without direct representation, it will not be carried. With regard to the gentlemen who retired after the meeting at Newcastle, I would say that several of them, just as I did with regard to the Medical Reform Committee, thought the better of it and returned, and one of them has given a "Yes" to direct representation. In opposition to that I would say that there is a gentleman who was for the Bill of the Association and direct representation, but who has given a direct negative in the present instance. That gentleman is now the representative of the College of Surgeons of Ireland on the General Medical Council; and it looks as if this has induced him to modify his views. Sir Dominic Corrigan distinctly said that he was the representative of the Queen's University, and I think Mr. Macnamara is decidedly of opinion that he is a delegate to represent the interests of the Irish College of Surgeons, and ought not to forego those interests for any conjoint scheme, or anything else that may be suggested in the way of medical reform.

The PRESIDENT: I wish to ask Dr. Waters what proportion of replies he had to the number of circulars sent out?

Dr. WATERS: Some of the circulars have no answer to direct representation; but, on mature thought, those gentlemen have signed petitions in favour of it, and those petitions will be presented to the House of Lords. This is the result of deliberation and consideration, and we find that the more men think of the matter the more do they come round to the necessity of direct representation on the General Medical Council. We had about 5,300 or 5,400 replies.

The PRESIDENT: How many were sent out?

Dr. WATERS: Sixteen or seventeen thousand.

Dr. QUAIN: On a former occasion, when the same question was asked, how many replies were received? were there not 9,000?

Dr. WATERS: I use no influence in Chester, but every man there will sign a petition for direct representation and the conjoint scheme, though I do not think more than one-third of the men there have sent replies. They throw the circular on one side; but I believe that if the men were got at the profession would be found to be almost unanimous in favour of direct representation. I believe we have got all the "Noes". Dr. Bell Fletcher spent about £200 in canvassing. If we

canvassed Liverpool and Manchester we should get the same proportion. I believe that the profession is almost unanimous in favour of these demands.

Dr. QUAIN: It is a very remarkable fact that on the occasion to which I refer, when Dr. Bell Fletcher's Committee sent a memorial to the Government, they had 9,000 persons in favour of direct representation. That was eight years ago. Since that time, the profession must have considerably enlarged.

Dr. WATERS: Dr. Bell Fletcher's canvass was made with energy, but it had no effect upon the Medical Council.

Dr. WALTER DICKSON: Have we not wandered from the real question, which is, whether we shall reject the first three items of reform set forth in these resolutions because we cannot get the fourth? I should be much pleased to see the fourth passed, but I am not disposed to refuse the three because we cannot get the fourth. I heard with great interest what fell from Dr. Stewart; and every member of the Metropolitan Counties Branch feels the utmost respect and gratitude to the Committee for the great efforts they have made for many years for the progress of medical reform. We are all anxious for the advancement and benefit of the profession, but we think there are different ways of attaining it. There is no doubt that medical reform embraces the conjoint scheme and direct representation; and I think, from the statement of Dr. Waters of the very small number of gentlemen who are inimical to these projects, that the whole profession may be considered unanimous on this matter; but we must take what we can get. There seem to be great practical difficulties in the way of direct representation. The corporations are very powerful. The members of the Medical Council sent by the corporations are simply delegates, representing moneyed interests. The corporations may improve. We know a great improvement has taken place even in our time. In our early days the College of Physicians and the College of Surgeons were very corrupt bodies, but they have done a great deal to reform themselves. Let us hope that the Scotch and Irish bodies may also reform themselves, and send representatives, not delegates. In some of these corporations there are not only the moneyed interests connected with the members themselves, but pecuniary interests for the benefit of widows and children of members of those corporations, and it therefore becomes very important to have as many people as possible examined; therefore I maintain that, paramount to this question of direct representation, comes the question of conjoint examination. In that way a great deal of real power would be taken away from the corporations, and you would find them much more favourable to the general interests of the profession than at present. Before sitting down, I beg to renew the assurance of the Branch that, so far from disparaging the efforts of Dr. Waters and Dr. Stewart, we look upon them with the greatest gratitude and respect, and feel that the Reform Committee has done an immense deal of good. But it is simply a question of practical attainment whether the one desirable end is not more likely to be attained than the other, and whether (as both in conjunction are unattainable) one alone cannot be got. On that ground I am inclined to think, and I think most members of the Branch will be of the same opinion, that the conjoint scheme of examination is the preferable of the two.

Rev. Dr. HAUGHTON: Although not a member of the Branch, I ask permission to address you. I am a member of the Medical Reform Committee who did not resign, and for this reason: that I agree with Lord Eldon, who said: "You can annoy your opponents much more by staying at your post than by resigning." I never intend to resign, and, as long as the Association does me the honour to keep me on the Reform Committee, I shall give my humble services to it. I certainly felt a considerable degree of admiration for the skill with which Mr. Hart got his snap vote at Manchester.

Mr. HART: I object to that adjective. The discussion was carried on in the most regular manner, and the vote taken in the usual way.

Rev. Dr. HAUGHTON: Then it was not a snap vote. I withdraw the word; but it was clever enough to deserve my admiration. It was a perfectly legal vote, and I accept Mr. Hart's correction. I do not think I ever looked at the wording of it, though I was present at the meeting. It did not revoke one jot or tittle of our former instructions, but a lid to them the instruction about the prosecution of quacks, whom I do not like any more than other people. Then the Medical Reform Committee, having cooled down a little from the heat of Manchester, were quite ready to carry out the instructions of the parent body. But there loomed in the distance the Government Bill, and we saw then that we had an opportunity of carrying out all the instructions; for nothing would be easier for us than to get that introduced as an amendment to the Government Bill. If it were not for this unhappy resolution No. 5, where, in the most disgraceful way, we show the white feather, I think we would carry out all the programme that the Medical Reform Committee were instructed to carry out; namely, the conjoint scheme,

direct representation, the prosecution of quacks, and the proper registration of fully qualified colonial practitioners. I may say another word of a personal character with regard to the exertions of the Committee. I certainly claim to have done my very best for the Committee. I frequently attended meetings held in Chester and elsewhere, and I did more than that: I used whatever influence I possessed in Dublin in favour of the objects of the Committee. I hold in my pocket at this moment a petition from the University of Dublin to the House of Lords, and I have brought instructions to our representatives in Parliament and our friends in the Government to give their entire support in favour of compulsory conjoint examination. It was like pulling a too h to get such a petition as that out of an old-fashioned body like the University of Dublin. They are a corporation, and all corporations are afraid to meddle with other corporations. Hawks do not pick out other hawks' eyes; therefore, corporations are always slow to go in for the conjoint examination. They have done so, however, in the long run, and I do claim for myself and the Medical Reform Committee a large share in the credit. The University of Dublin will not petition in favour of direct representation, but they will issue instructions to their representatives to offer no opposition whatever to it. Whatever reconstruction of the Medical Council Parliament, in its wisdom, considers it necessary to make, and must make, as a concession to the men who provide the money, the University of Dublin will not oppose; they will occupy no selfish position, and will not claim the right to have none but delegates, as I heard them called, on the Medical Council. I am not sure that you gain much by having representatives instead of delegates. The representative of the University of Dublin voted against the conjoint scheme, although the University which sent him there is petitioning in its favour. I think that delegation, with all its faults, is better than the unlimited licence given to your so-called representatives.

Dr. QUAIN: In justice to your admirable representative on the Medical Council, I must say that Dr. Apjohn was in favour of one conjoint board for the whole kingdom.

Rev. Dr. HAUGHTON: I am very glad to hear it. The fifth resolution is really a confession of weakness. If I am wrong, I can be answered at the right time. Ever since I recollect it, the Medical Association has always gone for these two great points, the compulsory conjoint scheme and direct representation; and we certainly have proved by waiting that a voluntary conjoint scheme is impossible, at least in Ireland. You remind me of the celebrated voyage of Jonah. You have taken for granted too hastily that we have a Jonah on board the ship; but, if there be a Jonah, I am fully persuaded that you are going to throw the wrong one overboard. I would ask you not to throw any one overboard, and you will carry your point. In the transaction of my University business, I have spoken with many Members of Parliament, and asked them their opinion about these two questions. I told them the profession wanted three things: the conjoint scheme, direct representation, and proper protection against quacks; and certainly, in the proportion of nine to one, they at once admitted that the men who pay the taxes ought to be represented. The whole of the money spent by the Medical Council is paid by the profession at large, and it is an unconstitutional thing—and that argument will tell powerfully in the House of Commons—to tax the profession without giving it representation. The question is not to be decided by medical men or by meetings; it is to be decided by the House of Commons and by votes. Allow me to tell you my experience about the Jonahs. How many votes could be brought up to resist direct representation? There is no strong interest against it. The corporations would like very well to be let alone, and have their delegates or representatives as at present, but there is no strong feeling against it. The delegate generally has a vested interest in the place; it brings him a certain amount of dignity and position, but the College cannot care much about that individual man, and he is the only person whose dignity will be hurt by direct representation. But, if you put forward compulsory conjoint examination, then they will bring up all their forces, and canvass every member in the country. The College of Surgeons of Ireland has a very powerful political party at its back. They have only to say: "Our money interests are in danger," and the members will vote straight for them. I, therefore, think if the Government would take up the direct representation and drop the other, the Bill would have a better chance of passing. The members of the Government have taken every opportunity privately to make themselves acquainted with the wishes of the great corporations. I do not speak with any authority; but I have reason to believe that the Government is most anxious to pass the Bill; and that, sooner than have it shipwrecked, it will accept both the compulsory conjoint examination and the direct representation. That being the case, I do really ask you to consider your decision. You are doing, I think, a rash and dangerous thing. You are certainly expressing a

doubt about the matter. I presume that every one in the room is in favour of direct representation, because the Association is committed to it by No. 4; but No. 5 is a hesitating, uncertain statement, and I think it really risks the whole thing. It shows that there is a division in our camp, and we invite defeat. To return again to my old friend Jonah. When Jonah went overboard, a friendly whale took him on shore, and he was as well as ever after the trip; but, if you drop your Jonah of direct representation now, he will sink into the sea deeper than ever plummet sounded, and no man living will ever see him again. I am only speaking as an outsider, but I am deeply interested in your success, and I think you are doing an unwise thing. It has been frequently said that "half a loaf is better than no bread"; but I think you risk the whole by trying to get your half loaf, and you will get nothing.

Dr. QUAIN: Perhaps I r. Stewart will remember when Exeter Hall was filled with reformers, including Dr. Marshall Hall, Dr. Grant, Dr. George Webster, and others. There were reformers in London as well as in the country, and you must not give all the credit to one party. I know what medical reform was in those days, but I would like to know what is now intended by the phrase. I know there are many abuses to be corrected, but they are not the things spoken of in the days when there were close corporations. That is all passed and gone. Dr. Waters says the Bill will not pass; I am sorry he does not help to obtain a Bill. I say that "half a loaf is better than no bread", and that you do not risk the whole by getting a part; but every opposition renders it more and more difficult to get this Bill through. I am not going to refer to the immense value of conjoint boards. From the first, I have seen the difficulties; but I believe that, if Scotland and Ireland would meet them with anything like a desire to overcome them, the difficulties would be found to be far less than they seem. For example, Dr. Wood pointed out the other day that it would be impossible to have a conjoint board in consequence of the number of persons to be examined; but the number would not be increased, and many of the persons would be examined only once, instead of three times. I do not think they go earnestly into the question, and see its value, and how it can be carried out; I believe that in Ireland and in Scotland the difficulties are much less than are imagined. Then, with regard to foreign and colonial practitioners, it would be a very great misfortune if a Bill registering colonial and foreign practitioners were carried without having some such clause as is suggested in the third resolution. But most important of all is this penal clause, when we know that in every direction quacks are imposing upon the public. So important is it to have a clause to prevent imposition, that almost everything should be sacrificed to obtain it. I do not myself see the great advantage of direct representation. I believe it is our duty to seek it in our colleges. I believe Dr. Haughton will tell you that the representative of the University of Dublin is nominated by six or eight persons. I think that is wrong. It is very much the same with regard to the Apothecaries' Society. I am surprised that the profession does not seek representation in its own Councils and halls, because it is there that the *morale* of the profession is really to be looked to. I believe that there has existed an error from the first with regard to the duties of the Medical Council. It is simply a body standing between the Government and the public. The public look to the Government; the Government in 1858 gave certain rights and privileges to members of the medical profession, and it is the duty of the Government to see that the persons to whom they give those rights are qualified for them. To my mind, direct or indirect representation has nothing to do with it. I should be very sorry if direct representation superseded the indirect right we all have to be represented in our own bodies. The gentlemen sent by the direct representation would not be one whit worse or better than the gentlemen sent now.

Dr. STEWART: Then why not admit them?

Dr. QUAIN: It would disturb the profession, as we see in the present election to the Council of the College of Surgeons. Look at the canvassing, the heart-burning, the ill-feeling that is likely to arise. Look at the letters that appear from week to week in the journals, and just imagine what would be the state of things if you had six or eight representatives to be chosen, not by the Fellows of the College of Surgeons, but by the whole medical profession. And where you say it would not cost much, I say the expense would be enormous. The talking power of the Council might be a little increased, because of course a representative who was elected by votes at large—

Rev. Dr. HAUGHTON: Would give value for his money.

Dr. QUAIN: He would feel it necessary to keep his name before the profession, in order that he might be re-elected; but I do not believe it would in the slightest degree add to the advancement of the profession to have this direct representation. In Scotland, it is quite true that all the representatives of the colleges are opposed to the conjoint

scheme, because it might to some extent affect their interests, but the excellent man who represents the Crown in Scotland voted with the minority on that occasion. I was sorry to hear Dr. Stewart talk a good deal about the funds of the colleges and corporations. As far as our London corporations are concerned, I do not believe it makes a pin's point difference to us. I am sure he will agree with me that the College of Physicians has made no use of its funds but for the interests of the profession; and I believe the College of Surgeons is not now much behind its sister.

Dr. STEWART: I wish to explain that I said if a measure greatly affecting the public were brought forward, it might perhaps involve pecuniary ruin.

Dr. QUAIN: The remarks of Dr. Haughton about taxation and representation deserve notice; as Mr. Hardy said, midwives and dentists would claim the same right on the same ground. But I would rather view that so-called tax in a different light. The tax is not imposed by the Medical Council. When first the University of London was founded, the University received the fees, and paid out their expenditure, and they received the balance from the Treasury to complete what was required. But after a time, it was found more convenient to pay all the funds into the Treasury, and thence to obtain the funds for carrying on the business of the University. Now on the same principle, if the Government of that day had said, "Let there be a £5 stamp on every register that is issued by the Medical Council", the money would have gone to the Treasury, and the expenses of the Medical Council would have been paid out of the Treasury funds. It is Parliament that has taxed the profession with this £5, not the Medical Council; they are merely the receivers of a tax imposed by Parliament; therefore, I do not think that the principle that taxation and representation ought to go together applies at all. Dr. Haughton, myself, and others, are all represented in Parliament by those who impose that tax.

Dr. WATERS: It was members of Parliament in the House to-day who insisted upon using that term, when I rather wished to speak of it as a registration fee. They insisted upon it that we describe ourselves as taxed.

Mr. HARDY: Before the resolution is put, I should just like to say a word with regard to the constitution of the Committee of Council of the British Medical Association. The Committee of Council can only consist of persons first elected into it or the Council by the Branches, and readers of addresses and presidents of sections, who also were not elected by the general body. It is indirect representation of the members through delegates of the Branches.

Dr. STEWART: That is a change that has taken place during the last year or two.

Mr. HART: I would suggest that there is an universal agreement as to the first four resolutions. As regards the last, what occurs to me is that, as this is a very small meeting, and as we are told that a large meeting of the Lancashire Branch has already passed a directly opposite resolution, it might be advisable not to come to a decided vote upon it. The importance of this meeting lies rather in the value of the speeches that have been made, than in any strength that could be given to those speeches by a vote. In fact, this is a meeting which has dwindled down to about fourteen or fifteen, and I do not think a vote of fourteen would give any weight one way or the other. I do not know whether that meets the view of the gentlemen who have taken so much trouble about it, and who have drawn this resolution; but, as the Branch generally has shown so languid an interest in the matter, I think it might be desirable that you should pass the first four resolutions and agree not to put the fifth.

Dr. QUAIN: Really, as that notice has been circulated, and it was open to other members to come, and we have sat here for two hours and a half, I think we should come to some decision.

Dr. WATERS: It will only be a proof of the little interest that the Metropolitan Counties Branch takes in the proposed resolutions. The profession *en masse* in reply to the circular has responded infinitely better, and I hope that the reply of the profession will have due weight allotted to it.

Dr. QUAIN: The curious thing is that the interest seems to be dying out.

Mr. J. S. TURNER: Two speakers have said that the dentists would claim to have a representative on the Medical Council if this representative system were carried. If the dentist is to be held up as a "bogey" to frighten people from direct representation, I must say that it is a very poor one, because their position is not and may not be established. They have no idea of asserting such a claim; though if it be a right no doubt they might assert it.

Mr. HARDY: It was not intended to cast any slur upon the dentists. It was said that the midwives and the dentists would have the same claim to a vote as the medical profession would have.

The PRESIDENT put the resolutions one by one. Resolutions 1, 2, 3, and 4 were carried unanimously; resolution 5 was carried by 7 to 4. It was agreed on the motion of Dr. QUAIN, that the resolutions be sent to the Lord President by the President and Secretary.

After a vote of thanks to the Chairman for conducting the business, the meeting was adjourned.

## THE MEDICAL ACT AMENDMENT BILL AND THE GOVERNMENT.

SEVERAL deputations have within the last few days waited on His Grace the Duke of Richmond, Lord President of the Privy Council, for the purpose of laying before him various views with regard to the amendment of the Medical Act. Subjoined are brief reports of the proceedings.

### DEPUTATION FROM THE MEDICAL REFORM COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

Since the introduction of the Duke of Richmond and Gordon's Medical Act (1858) Amendment Bill into the House of Lords, the Medical Reform Committee of the Association not only laid the views of the Association before the General Medical Council on April 17th, as reported in the JOURNAL of April 20th, but has also been favoured with two interviews with His Grace the Duke of Richmond and Gordon at the Privy Council Office. On the first occasion, the Committee made strong representations, first, as to the necessity of modifying the composition of the General Medical Council by the infusion of direct representatives of the profession; and, secondly, as to the formation of compulsory boards of examination in each division of the kingdom, on the principle of equal fees and uniform examination.

On Saturday last, May 18th, the Committee waited by appointment on His Grace the Duke of Richmond, in order again to confer with his Grace upon the Medical Act Amendment Bill. The Committee was represented by Dr. Eason Wilkinson, President of the Association; Dr. Waters of Chester, Chairman of the Committee; Dr. Chadwick, ex-President of the Association; Dr. Carpenter of Croydon, Lecturer on State Medicine at St. Thomas's Hospital School of Medicine; Dr. A. P. Stewart; and Mr. Manby of Wolverhampton, member of the Committee of Council. Dr. Grimshaw of Dublin, Chairman of the Council of the Irish Medical Association, was also present. The object of the deputation was again to represent to his Grace the advisableness of granting direct representation of the profession in the General Medical Council, in order to balance the undue preponderance of the representatives of the universities and corporations upon it, which, it was believed, had proved itself one of the greatest barriers in the way of medical reform. The result of the canvass of the profession was referred to as indicating the opposition which the Bill was certain to encounter in the House of Commons, if this prayer of the profession were not conceded. It was stated that several of those who had answered the question relating to direct representation in the negative had since signed petitions in favour of it; that a former member of the General Medical Council had given in his adhesion to it; that the President of the Irish College of Surgeons had also done so; and that corporations in Scotland and in Ireland had petitioned for it when the Bill of the Marquis of Ripon was before Parliament. The necessity for altering the permissive character of the Bill, by making the formation of conjoint examining boards compulsory, was also insisted on. Dr. Chadwick adduced the decision of the large and very influential meeting in London when he was President of the Association, where, it might be said, both principles were unanimously affirmed, as there was only one dissentient. Dr. A. P. Stewart referred to the past action of the Association in bringing the Medical Act of 1858 into existence, and dwelt on the injustice involved in the present exclusion from all privileges of those to whom the Act was due. Mr. Manby stated that, in his district, so few and far between were those who held a different opinion, that the profession might fairly be considered united on both points. Dr. Carpenter specially called attention to the composition of the Medical Council as constituting the chief obstacle in the way of all valid reform, and argued that the proposed change in the Council was of primary importance, for, once effected, the early enactment of all else would speedily follow.

Dr. GRIMSHAW, on behalf of the Irish Medical Association, addressed his Grace at considerable length in support of the memorial from that association, which he placed in his Grace's hands, and showed that the College of Physicians and the Irish Medical Association, as representing the feeling of the profession in Ireland, held similar views to those advocated by the British Association.

The DUKE OF RICHMOND said that he had given the representations made to him very careful consideration, and was prepared to make a concession as regarded the formation of conjoint boards, by making them compulsory in respect of the licensing corporations in Ireland and in Scotland; but insisted on leaving the universities free to give degrees as heretofore. Further than this, his Grace would not go. As to the question of direct representation, he did not express any decided opinion. On general grounds, it might be supported. It did not, however, form part of the Bill, and, if included in it, would at once be met by the opposition of the Marquis of Ripon.

The result of the canvass of the profession made by the Medical Reform Committee, as far as the returns had then been received, was placed in his Grace's hands. The result out of 5,227 replies was:

	AYE.	NO.
Direct representation ... ..	5,075	121
Conjoint scheme ... ..	4,910	264

His GRACE asked for a copy of the circular, which has been since forwarded.

#### DEPUTATION FROM THE UNIVERSITY OF LONDON.

A deputation from the University of London, consisting of Earl Granville, Sir John Lubbock, Dr. Storrar, Mr. J. Heywood, Sir P. Gray-Egerton, M.P., Dr. Sharpey, Dr. Quain, Sir William Gull, Dr. W. B. Carpenter, and others, also had an interview on Monday with the Duke of Richmond and Gordon.

Earl GRANVILLE explained the objects of the deputation, and said that they had not come to excite hostility against the Bill, but, on the contrary, to support it.

Dr. CARPENTER stated that their object was to secure uniform qualification in medicine and surgery for every one admitted to the practice of medicine. That had been the primary idea of the London University since its institution. They desired that there should be the highest qualification for a general practitioner. The conjoint scheme, while it would be better for the health and safety of the public, would render the condition of the general practitioner very much better and raise it also. There were many candidates who sought to enter the profession by the easiest access, and this they did by going to Edinburgh and Dublin. The deputation felt that the conjoint scheme could not be carried out in England, unless there were a similar test for degrees or stringency of examination for admission to the profession in Scotland and Ireland, and they hoped the Bill would be so framed as to make this necessary.

Earl GRANVILLE, Dr. STORRAR, and Dr. SHARPEY also spoke in favour of the conjoint scheme.

The Duke of RICHMOND and GORDON, in reply, said the Bill was for the benefit of the public generally. He was not before aware of the merits of a conjoint scheme, and if he had felt able to introduce it into the Bill in the first place, he did not consider it was possible to carry it through in that form. He had, however, proposed an amendment which would, he hoped, be the means of enabling England to avail itself of the conjoint scheme. He was aware that permissive legislation was always to be avoided if possible, and it might be objected that the legislation in his Bill was of a somewhat permissive character in regard to the universities. He did not think if there were a conjoint scheme for England comprising all the universities and corporations, that, therefore, many young men wishing to enter the medical profession, and not wishing to pass the examination of the conjoint board, would take refuge in Scotland, where they would pass a milder examination than would be admitted by the conjoint board; for so long as the Medical Council existed it had the power and the duty imposed on it of seeing that the examinations were of such a character as they thought they should be, and as would uphold the dignity and credit of the profession. The Bill made it necessary for each candidate to be qualified in medicine and surgery. He thought the state of things referred to could not exist after the Bill became law. He would consider all that had been stated.

#### DEPUTATION FROM THE ROYAL COLLEGE OF SURGEONS OF IRELAND.

A deputation from the Royal College of Surgeons of Ireland had an interview on Tuesday with the Duke of Richmond and Gordon (with whom was Mr. Peel) at the Privy Council Office.

Dr. ROBERT MACDONNELL, President of the College, and Mr. MACNAMARA, one of the Council, spoke, and proposed that, in order to make the Bill a really good one, there should be a double qualification, but that no medical authority should be able to give more qualifications than one—that was, either in medicine or surgery, but not in both; and that, if his Grace did not feel strong enough to carry such a measure, which would be made still more perfect if midwifery were

added as a distinct qualification, the deputation would approve a compulsory conjoint scheme embracing all the medical authorities in each of the three divisions of the United Kingdom rather than a partial conjoint scheme dealing with medical corporations only.

The Duke of RICHMOND and GORDON thought the suggestions made were most admirable; but, although he personally liked them very much, he was afraid they could not be embodied in the Bill with the hope of being successfully carried.

#### DEPUTATION FROM THE MEDICAL DEFENCE ASSOCIATION.

On Monday last, May 20th, a deputation of the Medical Defence Association had an interview with the Lord President at the Privy Council Office. Among those present were Dr. B. W. Richardson, F.R.S., Dr. C. J. White, Dr. H. M. Williams, Dr. W. B. Johnston, Mr. T. Cooke, Mr. W. Smith, Mr. J. W. Mason, Mr. F. H. Alderson, Mr. H. Adcock, Dr. J. G. Glover, Dr. Royston, Mr. G. Brown, Mr. Paramore, Mr. Bott, etc. The deputation was introduced by Dr. Richardson, who explained the objects of the Association, and presented a memorial which had been drawn up by the Council. Dr. Richardson said the Council was of opinion that, in any measure of medical reform, one of the first principles to be enforced was that no person should in future receive a licence to practise in the United Kingdom who had not satisfactorily passed a full and complete examination in medicine, surgery, and obstetrics. They suggested that diplomas and degrees should be regarded as honorary distinctions only, and should confer no right to practise unless the holder had also passed a State examination. The Council suggested that one-third of the members of the General Medical Council should be chosen by the Crown, one-third by the universities and corporations, and the remaining third by the members of the profession resident within the United Kingdom. They suggested that any assumption of a medical title by unregistered persons should be punishable, and where they practised medicine or surgery for gain without qualification, whether assuming titles or not. They proposed that fines, etc., recovered should, instead of being handed over, as at present, to metropolitan magistrates, be transferred to the Medical Council. They suggested also that dentistry and midwifery should be brought under a new Bill.

Mr. George Brown, Honorary Secretary to the Association, gave further explanations of the views of the deputation. He said that the interests of the medical corporations and of the profession were not identical, and that it was desired that the Government should, while avoiding injury to the corporations, adopt such measures as would be for the interest of the public and the profession. He called attention to the ease with which quacks evaded punishment, and advocated the establishment of a state examination, which everyone should be required to pass before being permitted to practise, the fee for which should be £10 or £15. He also called attention to the use of the names of qualified men by unqualified persons. He also pointed out that it was proposed in the Medical Acts Amendment Bill to admit unqualified foreigners to the Register. The deputation expressed their regret that women should be admitted to the medical profession in this country.

The DUKE OF RICHMOND and GORDON said that he thought the proposal for a State Board went rather against his Bill, and he would not hold out any hope that such a board would be formed. As regarded direct representation in the Medical Council, he could not undertake to alter the constitution of the Council in the present Bill, and he was afraid that, if such were proposed, it would have little chance of passing through Parliament. At the same time, he admitted that the matter was important. With regard to conjoint boards, he had given notice of an amendment, to the effect that the corporate bodies should, either alone or in conjunction with universities, frame conjoint schemes by the last day of December 1880 at latest.

After some remarks from Dr. GLOVER and Mr. FRIDHAM, the deputation thanked his Grace and retired.

#### DEPUTATION FROM THE MEDICAL ALLIANCE ASSOCIATION.

A deputation from the Medical Alliance Association waited upon the Duke of Richmond and Gordon on Tuesday, being introduced by Dr. Lush, M.P.

Mr. NELSON HARDY said that, on a former occasion, they came before the Lord President to urge the Government support to a Bill, which was brought in by Dr. Lush and Sir Trevor Lawrence, to remedy existing evils; and his Grace then stated that it was the intention of the Government to introduce a Bill of larger scope than the private Bill, and to take in all it proposed. The object the deputation now had in view was to point out the changes which they thought were required in the Government Bill, in order that the great bulk of the medical profession might be able to give the measure their cordial support. His Grace would have learned from the

various deputations that there were four principal points on which legislation was desired by the profession; namely, compulsory conjoint examining boards, amendment of the penal clause, registration of colonial and foreign degrees, and the representation of the profession on the General Medical Council. Of these, the three first mentioned were included in Lord Ripon's Bill in 1870, and it would be a great disappointment to the profession if any of the three were left unsettled by any Government Bill which passed into law. The first especially was desired by the profession at large, and the deputation trusted that his Grace would insert clauses to meet the points in Lord Ripon's Bill. As to the amendment of the penal clauses of the Act, and the registration of foreign and colonial degrees, dealt with in the Association's own Bill, his Grace had given reasons which had prevailed upon the Association waiting to see the Government Bill. The fourth point was one of much difficulty. It was evident that the Medical Council did not, in any proper sense, represent the profession, of which no better proof could be given than that, in their representations to the minister on the subjects requiring legislation, that body had actually omitted to refer to two out of these four points—the first and the last. As to the question in regard to the arrangement of the representation, whether by the votes of the whole profession for a certain number of representatives; whether the votes should be by ballot or taken by proxy; or whether, instead of as at present, the representatives of the different Colleges, being elected by the Council or other governing body, should be elected, as in the Universities, by the whole body of licentiates,—were all points open to discussion. With regard to midwives and dentists, who, under the Government Bill, were to be registered by the Medical Council, these might as well be dealt with in a separate Bill, as their presence would complicate the question of representation; and, seeing how difficult it was to pass a complete measure, the deputation asked the Government to support the smaller measure of the Association.

Dr. JOSEPH ROGERS expressed his dissatisfaction with the General Medical Council as at present constituted, and spoke of that body as doing nothing to raise the education and status of the profession. He introduced the subject of unqualified persons being brought in to attend upon the poor by the Poor-law medical officers, and urged that the Bill should provide against that great evil by making it an offence for an unqualified person to act in this manner.

Dr. R. H. S. CARPENTER dealt with the subject of "quack" doctors, who took upon themselves false titles and deceived the public by the display of diplomas never granted for medical knowledge, and some of these from pretended institutions which had no existence. He also asserted that certain of the British Colleges would grant degrees on a mere money payment; while the licensing bodies so played into each other's hands that the several degrees could be obtained on what were termed "modified examinations"—with the result that persons who were too ignorant to pass the "modified examination" at one place could get the diploma at another. He had known a person who had obtained a public appointment, and desired to have a degree as the necessary qualification, get the qualification, though told by one examining body that he ought not to be allowed to practise surgery and medicine. The speaker also showed his Grace specimens of certificates of death signed by unqualified persons, or signed by qualified persons who had never attended the deceased. This system, he urged, was fraught with evil.

The LORD PRESIDENT OF THE PRIVY COUNCIL thanked the deputation for the large amount of information they had laid before him, and promised to give his best attention to the subjects to which reference had been made.

#### DEPUTATION FROM THE MANCHESTER MEDICO-ETHICAL ASSOCIATION.

On Monday, May 20th, at the Privy Council Office, His Grace the Duke of Richmond and Gordon received a deputation of the Manchester Medico-Ethical Association, consisting of Dr. Royle, President, J. Broadbent, Esq., one of the Honorary Secretaries, and Dr. Tatham, the Chairman of the Parliamentary Committee of the Association, upon the Medical Acts Amendment Bill, and to present a petition to the House of Lords thereon. The deputation was accompanied by Sir Thomas Bazley, Bart., M.P., Hugh Birley, Esq., M.P., Jacob Bright, Esq., M.P., W. T. Charley, Esq., M.P., O. O. Walker, Esq., M.P., Edward Hardcastle, Esq., M.P., J. T. Hibbert, Esq., M.P. Dr. Glover was also present.

Mr. HUGH BIRLEY, who introduced the deputation, said that he was sure they had at heart, not only the interests of the profession, but also those of the general public. As the matter was of a technical and professional nature, he would leave it to the deputation to state their own case.

Dr. ROYLE, in presenting the petition for presentation, thanked his Grace for having brought in a Bill with the intention of putting medical legislation upon a more satisfactory footing; yet he was sorry to say that the Bill, as it now stood, would by no means remedy the evils or satisfy the profession. They had no wish to obstruct, but would do all in their power to obtain a satisfactory measure; and felt that, did they not come forward and express the sentiments of the profession, so far as they were concerned, they might be justly charged with neglect. No scheme of medical reform would satisfy the profession which did not secure direct representation of the profession upon the Medical Council, which now only represented the Crown, the universities, and the medical corporations; while all the fees which supported the Council were contributed by the profession as a body, who had no direct vote or direct influence over its proceedings. This direct representation of the profession might be easily secured, without increasing the present number of the Medical Council, by grouping together several of the medical corporations, and in place thereof giving six members, to be elected by voting-papers by the registered practitioners of the country. A certain number of proposers and seconders would be necessary for each nominated candidate; the nominations should be sent in by a certain date, and the list of the nominated should be sent to every registered practitioner, and the vote, properly attested, be returned by a certain day. The expense would be trifling, and if the profession had the power of voting and neglected to exercise it, it would be their own fault. There should be compulsory means for creating a uniform standard of the minimum of knowledge which would be required to qualify a person to practise medicine legally, and this would be effected by the formation of a conjoint board. The existing corporations should still grant their degrees, which would be of an honorary character. And it would be unwise to entrust the Medical Council with the power of conferring degrees upon foreigners, unless the said foreigners possess a recognised qualification in their own or some other country. With regard to the twenty-second, or penal clause, as now drawn, its evasion would be so easy as to be of little or no protection to the profession, since the penalties are inflicted not for practising medicine or surgery, but for taking or using the names descriptive of the qualified practitioners thereof. The petition was then handed in. [It was to the same effect as that of the Medical Reform Committee of the British Medical Association.]

His Grace the Duke of RICHMOND and GORDON, on receiving the petition, stated that what had passed should have his best consideration, as also any suggestion which might be made as to the penal clause; but with regard to the question as to direct representation, it could not possibly be introduced into this Bill; it would have to become the subject of a separate measure.

The deputation having thanked his Grace, withdrew.

#### DEATH WHILE UNDER THE INFLUENCE OF CHLOROFORM.

WE have to record a further death under this heading. For the particulars we are indebted to Mr. Martin Guisford.

Elizabeth P., thirty-four years of age, was admitted into the East Suffolk Hospital, under the care of Mr. Branford Edwards, on the 5th instant. She was suffering from fistula in ano, and was stated to have been of very intemperate habits. Two days after admission, she was brought into the theatre for the purpose of having the fistula operated upon. She was very nervous and greatly dreaded the operation, which she was strongly advised to undergo without anaesthesia; but this she positively refused to do. Accordingly, chloroform was administered, in quantities of half-a-drachm at a time, on a few folds of lint. Her pulse was rather feeble and quick, conditions which, in the absence of other symptoms, were attributed to her fear of the knife. The chloroform was slow in its effect; but, beyond considerable struggling and excitement at the end of the first stage, there were no unusual symptoms. As soon as anaesthesia was barely produced, not more than three drachms having been inhaled, the administration was discontinued. The character of the pulse had not materially altered, and the breathing, though somewhat rapid, was fair. The patient was now turned on her left side for the convenience of the operator, the fistula was examined, and a director inserted. Just as the division of the fistula was being performed, about two minutes after the withdrawal of the anaesthetic, the patient gave a sharp scream, the pupils dilated, urine was passed involuntarily, the face became pale, and, simultaneously, the heart's action and the pulse suddenly ceased, and, after a few moments, the breathing stopped also. Artificial respiration upon Howard's plan was immediately commenced, fresh air in abundance

was admitted into the room, interrupted shocks from a coil were applied over the heart, brandy was injected *per rectum*, and the right median basilic vein was opened. A few feeble respiratory movements occurred once or twice, but no heart-sounds could be detected. After more than an hour had elapsed, the attempt was abandoned as hopeless. At the *post mortem* examination, nineteen hours after death, the heart, as seen *in situ*, was firmly collapsed and very pale, and covered with a thick layer of fat. On removal, the organ weighed nine ounces and three-quarters, and its cavities were quite empty. The walls were remarkably thin and very pallid. Microscopical examination revealed well-marked fatty degeneration of the muscular fibres. There was a distinct patch, apparently atheromatous, on the mitral valve, and the base and transverse part of the arch of the aorta were atheromatous over a considerable extent. The other organs were very congested, but otherwise healthy. At the inquest, a verdict of "death from the action of chloroform on a diseased heart" was returned.

### THE ASSOCIATION IN IRELAND.

A CORRESPONDENT writes:—Thanks to the energetic help of Dr. Duffey of Dublin, Dr. Macnaughton Jones of Cork, and Dr. Moore of Belfast, there exist now promising Branches of the Association, with all the requisite organisation for giving united effect to the opinions and interests of our medical brethren in the northern, eastern, and southern provinces of Ireland. On the occasion of the recent visit of Dr. Wilkinson and Mr. Ernest Hart to Dublin, on the invitation of the Dublin Branch, a preliminary effort was made, through the kind aid of Dr. Lombe Atthill, to set in action a movement for affording a similar organisation to our members and their professional brethren in Galway and the western provinces, of which that town is a convenient centre. We understand that there is some prospect of such a movement being satisfactorily set on foot by the aid of Dr. Kinkead of Galway, whose energy and excellent professional relations would afford no small earnest of success.

### REPORT OF THE LUNACY LAW COMMITTEE.

WE referred lately to the report of the Select Committee appointed to inquire into the operation of the Lunacy Law. The following is a summary of its text.

The attention of the Committee, the report states, was mainly directed to three questions: 1. Whether a possibility exists of persons being unduly deprived of liberty by means of a false allegation of lunacy; 2. Whether persons properly detained are placed under restraint of a nature calculated to retard their cure and consequent discharge; 3. Whether undue obstacles are opposed to their release when restored to sanity. The report continues: "Upon all these points, the Committee received copious evidence, which led them to the conclusion that, although the present system was not free from risks which might be lessened, though not wholly removed, by amendments in the existing law and practice, yet, assuming that the strongest cases against the present system were brought before them, allegations of *mala fides* or of serious abuses were not substantiated. Much of the evidence, which extended to great length, amounted to little more than differences of opinion among medical men, questions of liberality or parsimony in the arrangements of asylums, suggestions with reference to the letters of patients and visits of friends, or complaints of hesitation among superintendents and relatives to believe in the perfect recovery of patients. Instances of the detention in asylums of persons who might be discharged were given, suggestive of wrong-doing, which subsequent investigation materially qualified. It was admitted that many of these persons were not sane, and that they could not safely be discharged unless they had friends who would be responsible for them. And with reference to the charge that paupers were frequently sent to asylums in cases of ordinary mental enfeeblement when they ought to have been retained in the wards of workhouses, the Committee are of opinion that such proceedings, though irregular, and liable to objections on the ground of expense, could hardly be called injurious to the patients themselves, except (if, indeed, this be an exception) by removing them farther from their homes and friends, if they have any, and were sometimes resorted to for the sake of other inmates who were annoyed by the habits of those who were imbecile. The Committee cannot avoid observing here, that the jealousy with which the treatment of lunatics is watched at the present day, and the comparatively trifling nature of the abuses alleged, present a remarkable contrast to the horrible cruelty with which asylums were too frequently conducted less than half a century ago; to the apathy with which the exposure of such

atrocities by successive Committees of this House was received, both by Parliament and the country; and to the difficulty with which remedial enactments were carried through the Legislature, while society viewed with indifference the probability of sane people being in many cases confined as lunatics, acquiesced in the treatment of lunatics as if they were outside the pale of humanity, and would have scarcely considered a proposal to substitute for chains and ill-usage the absence of restraint, the occupation and amusement which may be said to be the universal characteristics of the system in this country at the present day. Nevertheless, the anomalous state of the law, which undoubtedly permits forcible arrest and deportation by private individuals, and the fearful consequences of fraud or error, have induced the Committee carefully to inquire whether any additional safeguards may be devised." The report goes on to refer to several points in the evidence, and the Committee observe that they believe that the surest mode of guarding against unduly prolonged detention in asylums consists in frequent and careful visitation of all places in which any lunatic is confined, with full power placed in the hands of the Commissioners to order his discharge, and in the more general adoption of the system of probationary release. They think that the difficulty attending, in certain cases, especially in Scotland, the discharge of patients who cannot be certified as entirely sane, but still are no longer dangerous to themselves or others, and not likely to be benefited by further detention, may be obviated by such means. There appears, the Committee say, to be a general concurrence of opinion that the best security against the undue detention of patients consists in personal examination, such as that by the Chancery visitors. Every person discharged from confinement in a lunatic asylum should, with the consent of the Commissioners, have access to all documents connected with his detention therein. Some of the changes in the law recommended by the Committee may, they remark, be carried out by a mere change of practice, others would necessitate amendments in the statute law of the realm; under any circumstances, a consolidation of the Lunacy Acts would be most desirable. Any such changes as they have indicated would, they venture to think, "tend still further to improve the method already so immensely improved, of dealing with those unhappy persons who suffer under mental derangement, and would increase public confidence in a system which is not unnaturally, and perhaps not undesirably, regarded with a considerable amount of jealousy and distrust."

### UNIVERSITY OF LONDON.

THE following is the list of candidates duly elected at the recent annual meeting of Convocation to serve on the Annual Committee for the coming year. *Faculties of Medicine and Science:* \*Baines, M., M.D.; \*Baxter, E. B., M.D.; \*Beck, M., M.S., M.B.; Buchanan, G., M.D., B.A.; \*Coulpland, W. C., M.A., B.Sc.; \*Curnow, J., M.D.; \*Fagge, C. H., M.D.; \*Flight, W., D.Sc.; \*Holman, W. H., M.B.; \*Howse, H. G., M.S., M.B.; \*Kisch, B., M.A., B.Sc.; \*Magnus, Rev. P., B.A., B.Sc.; \*Morris, H., M.A., M.B.; \*Poore, G. V., M.D., B.S.; \*Pye-Smith, P. H., M.D., B.A.; \*Taylor, Frederick, M.D. *Faculties of Arts and of Laws:* \*Austin, James, B.A.; \*Aspland, L. M., LL.D., M.A.; \*Bompas, H. M., M.A., LL.B., Q.C.; \*Bask, E. H., M.A., LL.B.; \*Charles, A., B.A., Q.C.; \*Dunn, E. C., B.A.; \*Ely, T., M.A.; \*Foster, G. C., B.A.; \*Gree, C. J., LL.D.; \*Harrop, Robert, M.A.; \*Hennell, John, B.A.; \*McDowall, A., B.A., B.Sc.; \*Murch, C. J., B.A.; \*Payne, J. Horne, M.A.; \*Shaen, W., M.A.; \*Weymouth, R. F., D.Lit., M.A. An asterisk is prefixed to the name of every candidate who was a member of the Annual Committee during the past year.

## SPECIAL CORRESPONDENCE.

### PARIS.

[FROM OUR OWN CORRESPONDENT.]

*Dieulafoy on Thoracentesis in Pleurisy.—Peter on the Temperature in Pleurisy.*

SINCE the introduction by Trousseau of thoracentesis in ordinary practice, the operation seems to have been very generally adopted, in this country and elsewhere, as a remedial agent for the cure of pleurisy; but, judging from statements made at a recent meeting of the British Medical Association, and from a paper submitted to it by Dr. Wilson Fox, the results are anything but encouraging. Dr. Dieulafoy, however, one of the most brilliant pupils of Trousseau, and faithful to the teaching of his illustrious master, has, in a work just published, en-

deavoured to show that the non-success of the operation is often due to its too indiscriminate employment in all cases of pleuritic effusions, to the defective mode of operating, and to the kind of instrument employed. In the work just alluded to, and which is entitled *La Thoracentèse par Aspiration dans la Pleurésie Aiguë*, Dr. Dieulafoy states that the abuse of the operation in question arises from the facility with which it is practised with the "aspirator". After passing in review the various instruments employed in the operation, from Trousseau to the present time, Dr. Dieulafoy, of course, prefers that which bears his name. Many objections have been made against his own instrument; but these he removes without much difficulty. For instance, it has been objected that thoracentesis might convert simple serous pleurisy into the purulent form; but, although Dr. Dieulafoy does not deny the possibility of such a result, he asserts that it cannot be attributed to this cause alone, as there are hundreds of cases where the chest had not been opened, and yet pus was formed in the pleural cavity; the transformation, he adds, is the natural process in a certain form of serous pleurisy, in which, whether thoracentesis be practised or not, suppuration is the inevitable result, unless, indeed, resolution or the reabsorption of the fluid had already taken place. The mechanism of this form is very ingeniously explained by the author, for a description of which I must refer your readers to the work itself. Other accidents have also been ascribed to thoracentesis: oedema and congestion of the lungs, albuminous expectoration, asphyxia, cardiac and pulmonary thrombosis, and embolism—all of which he disposes of with great talent, if not with great success. Among the different methods employed in the practice of thoracentesis, the aspiratory method has been condemned in some quarters as being more likely than the other methods to produce the above and other unfavourable results. This objection becomes more personal, as it is well known that the name of Dieulafoy is most intimately connected with the aspiratory method of thoracentesis; and, so far back as 1869, he introduced this method, or rather the instrument that bears his name, a full description of which is given in his work, published in English by Smith, Elder, and Co., and which is entitled *Pneumatic Aspiration*. In the brochure under notice, Dr. Dieulafoy gives some useful hints and rules as to indications for thoracentesis and the mode of employing his aspirator-needle. The most urgent indication is founded on the quantity of pleuritic effusion, which the author fixes to from 1,800 to 2,000 grammes, or from 3 to 3½ pints, as the maximum with which the operation can with any degree of safety be put off; and, even when then this quantity is reached, the operation should be performed at once, as in this case, perhaps more than in any other, delays are dangerous. The author gives some signs by which the existence of the above quantity in the pleural cavity may be ascertained, and recommends that, when the quantity is attained, the operation should be performed without delay, whether the patient be still in the febrile stage or not, or even if the dyspnoea do not appear urgent. This applies to simple acute pleuritis; but, if it be complicated with other morbid conditions, the physician or surgeon must be guided by individual circumstances. When thoracentesis is decided upon, no more than 1,000 grammes of the pleuritic fluid should be drawn off at a time; the operation may be repeated as often as is necessary, and this precept applies more particularly to old and complicated cases of pleurisy, in order to prevent congestion of the lungs and other accidents referred to above, which may be induced by the sudden removal of the pressure to which the lungs had been subjected by the pleuritic fluid; and in this way even the lobes on the sound side may become similarly affected. For the same reason, the withdrawal of the fluid should be performed gradually and slowly; and this is better effected with No. 2 of Dieulafoy's needles, of which there are four sizes, than with any other instrument. The concluding chapter of the brochure describes the manner of operating with the aspirator-needle; and it, according to the author, the rules he there laid down be strictly observed, thoracentesis may be performed with greater safety than with any other trocar or instrument.

*A propos* of pleurisy, I may notice that Professor Peter, another of Trousseau's most distinguished pupils, lately read a very interesting paper, before the Academy of Medicine, on the comparative thermometry between the healthy and diseased sides of the chest in this affection. According to Dr. Peter, the temperature of the side affected with pleurisy is always greater than that of the sound side; and this increase of temperature continues in proportion to the effusion, and may even reach 2.5 and 3 deg. C. above the normal standard. It then falls when the secretion stops; but, nearly always, it continues by 0.5 to 1.5 of a degree in excess of the temperature of the healthy side. This hyperthermy persists even after the reabsorption of the effused liquid, and it is this persistence that explains the possibility of relapses. In cases of dry pleurisy, or pleurisy without effusion, the local hyperthermy is less elevated than in pleurisy without effusion, and the return to the normal

temperature takes place more rapidly. The above applies to pleurisy left intact or unrelieved by thoracentesis; but, when the operation is performed, the local hyperthermy is the consequence of hyperæmia *a vacuo*, as takes place in ascites. In cases of pleurisy, this hyperæmia, which is altogether local, is necessarily added to the previously existing phlegmatic hyperæmia, against which the operation was without curative action. Thus we have two hyperæmies instead of one, with all their consequences—such as augmentation of tension in the blood-vessels of the inflamed pleura, purulent transformation of the effused liquid, syncope, pulmonary congestion, consecutive albuminous expectoration, pain, dyspnoea sometimes amounting to suffocation. The conclusions arrived at by Dr. Peter rather tend to show that thoracentesis is not, after all, so inoffensive an operation as it is made out to be by some enthusiasts; and it behoves every practitioner to pause and consider well before he would thrust an instrument into a patient's chest.

## ASSOCIATION INTELLIGENCE.

### EAST YORK AND NORTH LINCOLN BRANCH.

THE annual meeting of this Branch will take place at the Infirmary, Hull, on Wednesday, May 29th, at 2 P.M.

Gentlemen intending to bring forward any communications, or to propose resolutions, are requested to inform the Secretary without delay.

Dinner at the Vittoria Hotel at 5.30 P.M.

E. P. HARDEY, *Honorary Secretary*.

Hull, May 20th, 1878.

### BATH AND BRISTOL BRANCH.

THE sixth ordinary meeting of the Session will be held at the Museum and Library, at the top of Park Street, Bristol, on Wednesday evening, May 29th, at half past Seven o'clock; H. MARSHALL, M.D., President.

The evening will be devoted to a discussion on Alcohol in Health and Disease, which will be introduced by Dr. E. L. Fox.

E. C. BOARD, } *Honorary Secretaries*.  
R. S. FOWLER, }

7, Caledonian Place, Clifton, May 14th, 1878.

### SOUTH EASTERN BRANCH: WEST SUSSEX DISTRICT MEETINGS.

THE next meeting of this District will take place at the Marine Hotel, Worthing, on Thursday, May 30th, at 3.15 P.M.; A. H. COLLET, Esq., in the Chair.

The dinner will be served at 5.30 P.M.

Notice of intended communications is requested by the Honorary Secretary on or before Tuesday, the 21st instant, for insertion in the circular convening the meeting.

WM. J. HARRIS, *Honorary Secretary*.

13, Marine Parade, Worthing, May 11th, 1878.

### BORDER COUNTIES BRANCH.

THE spring meeting of this Branch will be held at the Keswick Hotel, Keswick, on Friday, June 7th: President—Dr. LOCKIE; President-elect—Dr. GILCHRIST.

Gentlemen intending to read papers, or to be present at the dinner, are requested to give notice to the Secretaries.

R. MACLAREN, M.D., Carlisle, } *Honorary Secretaries*.  
JOHN SMITH, M.D., Dumfries, }

Carlisle, May 11th, 1878.

### THAMES VALLEY BRANCH.

THE next general meeting will be held on June 13th, at the Greyhound Hotel, Richmond, at Six o'clock.

Papers will be read by—

1. Mr. Balmanno Squire: The Use of Chrysophanic Acid.

2. Dr. Trouncer:

3. Dr. Atkinson: Vaccination and Revaccination.

Dinner at the above hotel at Seven o'clock. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Honorary Secretary*.

Kingston-on-Thames, May 13th, 1878.

## STAFFORDSHIRE BRANCH.

The third ordinary meeting of the Session will be held at the Mines' Drainage Office, 22, Darlington Street, Wolverhampton, on Thursday, May 30th, at 3 o'clock P.M.

VINCENT JACKSON, }  
J. G. U. WEST, } *Honorary Secretaries.*

Wolverhampton, May 5th, 1878.

## EAST ANGLIAN BRANCH.

The annual meeting of the above Branch will be held at Peterborough, on Friday, June 21st, at 11.30 A.M., in conjunction with the Cambridge and Huntingdon and South Midland Branches: THOMAS J. WALKER, M.D., President-elect, in the Chair.

After Branch preliminary business at 11.30, there will be a general meeting about 12.15, when the President-elect will read an address; at the conclusion of which, he kindly invites members to luncheon at his house before the next general meeting at 2.15 P.M., for papers, discussions, etc.

Gentlemen wishing to read papers, or to dine, are requested to communicate as early as possible with one of the Honorary Secretaries.

WM. A. ELLISTON, M.D., Ipswich. }  
J. B. FITT, M.D., Norwich. } *Honorary Secretaries.*

Norwich, May 14th, 1878.

## MIDLAND BRANCH.

The annual meeting of this Branch will be held at Lincoln, on Thursday, June 27th: President—C. H. MARRIOTT, M.D.; President-elect, A. MERCER ADAM, M.D.

Members desirous of reading papers are requested to communicate with C. HARRISON, M.D., *Honorary Secretary.*

Lincoln, May 14th, 1878.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 14TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

## CONTRIBUTION TO THE PATHOLOGY OF HÆMOPHILIA.

BY P. KIDD, B.A.

In this paper, a description was given of a case of hæmophilia in a child six years old, in which fatal hæmorrhage occurred from the mucous membrane of the mouth. A short clinical history of the case was given, with an account of the *post mortem* examination. The blood was examined, and was found to be very watery, and to contain a large excess of colourless corpuscles. A microscopical examination was made of the aorta and vena cava, and of that part of the mucous membrane of the mouth from which the fatal bleeding took place. This examination revealed an extensive affection of the small vessels, arteries, veins, and capillaries, especially the smallest veins. This affection, which mainly consisted in a great proliferation of the epithelioid cells lining the vessels, was seen in the small vasa vasorum of the aorta and vena cava, as well as in the vessels of the submucous tissue of the mouth. The coats of the aorta and vena cava themselves were healthy. Drawings were given of the affected vessels and also of a portion of the surface-epithelium of the mouth, which had undergone a peculiar change, described in the paper. A certain number of small arteries of the oval mucous membrane had undergone a further change in addition to the epithelioid proliferation. This consisted in a degeneration of their muscular coat, which was seen to contain only a very small proportion of its normal structural elements. The conclusion was drawn that in this case there was a general disease of the small vessels. But, as the blood was also affected, there still remained the question whether this was primarily a disease of the blood or of the blood-vessels.

## ON THE PATHOLOGICAL TRACES OF PULMONARY HÆMORRHAGE.

BY REGINALD E. THOMPSON, M.D.

The traces of pulmonary hæmorrhage most frequently found in the lungs after death were stated to be small rounded or ovoid masses which varied in size from a pin's head to a filbert, and varied in colour according to their age from a blood-red to an ivory white. They were smooth, firm, and tough in texture, and were found to consist of blood-corpuscles and fibrin, packed closely in the alveoli. Their position was peculiar, and the special localities which they haunted indicated

that the force of inspiration was the active power by which the blood was impacted in the alveoli. Hence these traces indicated hæmorrhage transferred from some other distant part in the lungs. Their future condition appeared to depend upon the absence or presence of other pulmonary disease. There were other traces which indicated extravasation of blood *in situ*; in these cases, which were more rarely met with, there was considerable pigmentation of the neighbouring tissue, and occasionally laceration. In either case, whether the blood were transferred from a distance or deposited *in situ*, softening and elimination might occur, so that a cavity might be the result; but it was very difficult to form an opinion with reference to the relation of these hæmorrhagic deposits and tubercle.

Dr. E. SYMES THOMPSON said that the paper now read was of great value, as representing the pathological aspect of the subject. It tended to show that not only might there be secondary hæmorrhagic changes in a lung already affected, but that in an otherwise healthy lung hæmorrhage might occur, and be followed by a series of changes such as were described in the paper.—Dr. THEODORE WILLIAMS said that there was too great a tendency to call the masses found in the lungs, in cases of phthisis, caseous, or tubercular, or something of the kind, without sufficient examination. Dr. Thompson's paper was hence valuable; but he did not think he had made out that the putty-like masses were due to blood.—Dr. DOUGLAS POWELL expressed a doubt whether the force of inspiration was greater in one part of the lung than in another, as Dr. Thompson supposed. It was difficult to imagine how the changed blood could remain recognisable at the end of many months.—Dr. R. THOMPSON had in many cases found hæmoglobin in the masses. He thought that all portions of the lungs did not expand equally.

## THE BRAIN IN CONGENITAL ABSENCE OF ONE HAND.

BY W. R. GOWERS, M.D.

The subject was a man in middle life. The left hand was absent from birth in front of the carpus, the carpal bones being imperfectly developed and united. They were covered with a fibrous capsule, into which most of the muscles of the forearm were inserted. None of them were absent except the extensor minimi digiti. The ganglia at the base of the brain were equal in size. The convolutions of the frontal lobes were equal in size, including the ascending frontal convolution. The middle third of the ascending parietal convolution on the right side was only half the size of the corresponding part of that on the left. The upper and lower extremities of this convolution were equal on the two sides. Microscopical examination showed no alteration in the structure of the affected part; the smaller convolution having layers of grey substance of the same thickness, and presenting cells as numerous and as conspicuous as the other. The only difference was in the extent of the convolution. The other convolutions of the parietal and occipital lobes were equal in size. It was pointed out that the smaller area was precisely that, stimulation of which, in the experiments of Ferrier on monkeys, caused movements in the hand, which was in this case wanting. The absence of any change in the structure of the convolution might be due to the persistence of all the muscles of the forearm, or to representation and localisation in the brain being not exclusive, merely preponderant.

## ABSCESS WITHIN THE THORAX, ACCOMPANIED BY PULSATION.

BY JOHN TOPHAM, M.D.

The enlargement, which was consequent upon a blow from a mangle received by a laundress aged 21 in March 1871, was not noticed till nine months afterwards, having been preceded by pain in the part injured six months from the accident. There was a hemispherical enlargement at the left margin of the sternum, between the third and fourth ribs, pulsating synchronously with the heart. Both heart-sounds were audible through the swelling. The conclusion arrived at by the author was that the case was one of abscess; but, it being supposed to be aneurism, the patient was confined to bed in an infirmary during three years, the enlargement increasing gradually. At the end of six months, both sounds of the heart became audible in the back. Pressure did not change the size of the swelling, but the skin became inflamed over the prominent part. In June 1876, ulceration having set in, there was a discharge of thick pus, followed by a quantity of cheesy-looking substance, consisting under the microscope of large round corpuscles resembling white blood-corpuscles, or those of pus, which were undergoing fatty degeneration. Both sounds of the heart were audible in the back. The pulse at the wrists was irregular (be, tween 50 and 60 a minute). Systolic murmurs were heard at the heart's apex, none at the base; there was a loud "*bruit du diable*" in the neck at the lower outer edge of the sterno-mastoid; "loud *bruit* with the first sound, but louder and of higher pitch, on the left". The

patient left the infirmary; and in March 1876 the heart was in the natural position and the sounds natural, but the pulsations were irregular. In November 1877 there was still occasional discharge from the aperture; but the patient, now a domestic servant, was able to labour at her employment.

AN ANATOMICAL REMEDY AGAINST RESPIRATORY OBSTRUCTION FROM THE TONGUE, EPIGLOTTIS, AND VELUM PALATI IN THREATENED APNŒA FROM ANÆSTHETICS OR OTHER CAUSES.

BY BENJAMIN HOWARD, M.D.

The object of the paper was to give the results of various and repeated investigations and experiments. The facts to be presented confirmed the alleged respiratory obstruction from the tongue, epiglottis, and velum palati in apparent death in the ordinary supine position, and showed how such obstruction was promoted by the customary elevation and flexion of the head and neck. Traction upon the tongue, however firm, might open the pharynx, which its retreat had closed, but nothing more; the epiglottis remained unlifted. Other facts were then presented, proving how, by simple position, all these obstructions were instantly and simultaneously removed. The position consisted in elevation of the thorax and complete extension backward of the head and neck. By this means, the line of gravitation of the tongue was shifted from the back of the pharynx to the hard palate at or about its junction with the soft palate. The entire posterior wall of the pharynx was shifted backward; its anterior wall was shifted forward; thus, its antero-posterior diameter, as much as was possible, was throughout increased; while, by the shifting upward and backward of the nares, their entrance was brought more directly over and in a line with the course of the pharynx. The larynx being pulled downward and forward by the sterno-thyroidei muscles and fixed there, the extensive motion upward and backward of the lower jaw put upon the stretch the genio-hyoidei, mylo-hyoidei, and anterior bellies of the digastric muscles, causing the hyoid bone, and, by means of the hyo-epiglottic ligament, the epiglottis, to share together the motion of the jaw. Thus, the epiglottis was instantly made vertical. The thyroid insertion of the palato-pharyngeal muscles being brought downward and forward by the sterno-thyroidei and fixed; the palato-pharyngeal muscles were put upon the stretch their whole length by the extensive movement upward and backward of the head; and thus the posterior pillars of the fauces, the arches of the palate, and the velum palati, into which latter membrane these muscles were inserted, were all pulled downward and forward; they were thus made tense and kept so. The velum being thus stretched some distance in front of the back of the pharynx, a post-oral air-way was secured, from which the tongue was doubly excluded. Hitherto, in the treatment of apnœa and asphyxia, the tongue had been withdrawn only in those exceptional cases where a surgeon with forceps had been present. The means of complete elevation of the epiglottis in cases of apnœa had been hitherto unknown. The position described removed both those obstructions without assistant or instrument. The author, from the facts given and from other experience, urged that always in the induction and condition of anæsthesia the head should rest rather lower than the shoulders. He also stated that complete extension backwards of the head and neck should be the first and instant measure in threatened or actual apnœa, both as a remedy and as the first step towards success in artificial respiration. The withdrawal of the tongue when practicable, the author considered highly advantageous, though not necessary; but it should incur as little lowering of the inferior maxilla as convenient. Finally, the author claimed to have demonstrated that, contrary to the general belief, traction upon the tongue, however firm, cannot materially elevate the epiglottis; that he had discovered a simple way by which (1) the tongue is excluded from the pharynx without manipulation; (2) the epiglottis is elevated vertically at will; (3) an unobstructed post-oral air-way is secured from the glottis to the nares—all of which is effected simultaneously by position alone. These facts had received corroboration from recent observations upon anæsthetised patients; and the author was glad to believe that, in averting apnœa, in restoring from apnœa, and in enabling various means of artificial respiration to be used more effectively, the simple position above directed will be a frequent means of saving human life.\*

\* These facts have been demonstrated at King's College Hospital, at the Royal College of Surgeons of England, at Guy's Hospital, etc. After the earlier demonstrations, in view of the novelty and importance of the facts shown, statements that they had been satisfactorily seen were written by Dr. Gerald F. Yeo, Professor of Physiology, Mr. E. H. Howlett, House-Surgeon; and several others of King's College. At a later date, the following statement was made.

\* Guy's Hospital, *Post Mortem* Theatre, April 24th, 1878.—We have to-day witnessed a demonstration by Dr. B. Howard, which showed—1. That traction upon the tongue did not elevate the epiglottis (stirred it only, and pulled it slightly for-

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 26TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Ovariectomy in a Child aged Twelve Years.*—Dr. T. BARLOW read notes of this case, which had been under the care of himself and Mr. Howard Marsh at the Children's Hospital, Great Ormond Street. The enlargement was on the right side of the child's abdomen, and consisted on the extreme right of a hard mass, internal to which, and attached to it, was a tight cyst. The whole tumour was slightly movable and painless, and had been eighteen months growing. The child had scarcely any symptoms; she suffered only from a little constipation. Her temperature was normal. Chloroform having been given, a hypodermic syringe was introduced into the cyst two inches below the umbilicus, and one drachm of clear straw-coloured fluid was withdrawn. Next day, the temperature had risen to 99.4 deg. Four days subsequently, the tumour was considerably collapsed, the abdominal surface was flattened, and the hard part of the tumour was now quite definite. It evidently contained some material as hard as bone. The cyst had become quite soft and flabby, and gave no evidence of fluid. After about six days, the cyst refilled. Fifteen days subsequently, it was completely aspirated, and six pints of fluid were removed. The cysts, however, again filled. Ovariectomy was then performed by Mr. Marsh. There were no adhesions between the tumour and its surrounding parts. When it had been thoroughly exposed by the incision into the abdomen, it was tapped, and eighty ounces of light brownish green fluid were drawn off. The remaining solid portion of tumour was still too large to be drawn through the opening, which was three inches long, it was consequently extended nearly to the pubes. The thick and fleshy pedicle was clamped by Mr. Spencer Wells's method and divided. Bleeding points in the omentum were secured with catgut; and the wound was closed with deep silver sutures. No subsequent bad symptoms occurred. Pain in the abdomen was treated with morphia suppositories. After the eighth day, several sutures were removed; the bowels acted spontaneously on the twelfth day; and the clamp dropped off the pedicle on the thirteenth day. For some weeks, the stump of the pedicle remained protruded and covered with florid granulations. It at length became completely retracted, and the child was discharged well about eleven weeks after the operation. The tumour weighed two pounds eleven ounces; it measured six inches across, and seven inches from above down, and was nearly spherical in shape. The lower half was composed of a thin-walled cyst, capable of holding a large cocoa-nut; it had projecting into its cavity several smaller cysts. The hard part contained a plate of bone measuring two inches by four inches, and other smaller pieces of bone. There were cysts at the upper and outer part of the growth, with gelatinous and solid contents; many of which contained sebaceous matter, with collections of dark short hairs. There were also fibroid bands and irregular spicula of bone interposed between some of the cysts.

The PRESIDENT, upon inquiry, was informed that the child had not menstruated.—Mr. MARSH remarked that such operations in children were by no means unique. Mr. Spencer Wells had operated successfully upon a child eight years old; and in the *American Journal of the Medical Sciences*, there was a record of successful operation where the child was only seven years old. At Bonn, a child aged two years had been operated upon and perfectly recovered. In all the cases, he believed the cysts were dermoid.—Mr. MAUNDER said one important feature in connection with cystic tumours of the abdomen was the question of a preliminary tapping. He had known and doubtless others present were acquainted with instances in which the simple tapping of an ovarian cyst had led to fatal peritonitis. He was, therefore, strongly of opinion that this should not be done, except in obscure cases and as an aid to diagnosis. The case under consideration indicated a leakage into the peritoneal cavity, notwithstanding the small instrument that had been used; but, fortunately, no serious result followed. Assuming the radical operation justifiable in a given case, it is very undesirable to submit the patient to additional risk without corresponding advantage.—Dr. WILTSHIRE remarked that in dermoid cysts the fluid was made up of decomposed skin-products, etc., which, oozing into the peritoneum through the puncture made with the cannula, was very apt to set up peritonitis. In a patient with such a cyst, he had seen a severe

ward; 2. That extension of the cervical spine upon itself, and extension of the head upon the neck, with elevation of the lower jaw, caused complete elevation to a vertical position of the epiglottis; tension of the velum palati preventing falling of the dorsum of the tongue upon the back of the pharynx, and ensured an unobstructed passage from the glottis to the nares.—(Signed) Thomas Bryant, Surgeon and Lecturer on Surgery; C. Hilton Fagge, M.D., Lecturer and Demonstrator of Pathology, etc.; F. A. Mahomed, M.D., Medical Registrar; C. J. Symonds, Demonstrator of Anatomy.

attack of peritonitis supervene upon tapping. After her recovery, a second cyst filled; this had been opened, and still remained open. In most children, cysts of the ovary were dermoid.—Dr. COUPLAND stated that the fluid drawn off in this case was thin and pellucid, and came up through a hyalodermic syringe; consequently, this cyst was not dermoid.—The PRESIDENT said that as the fatal results which might ensue from these tapplings were well known, it seemed desirable to draw off a large quantity of fluid, that the cyst might collapse and no further fluid exude. When only a small quantity was drawn off, the tension of the cyst wall was scarcely diminished.—Dr. BARKER said that at Great Ormond Street, in very many cases of use of the hypodermic syringe, no harm had resulted. In regard to hydras also, even if (after tapping) the remaining fluid exuded into the peritoneal cavity, no harm seemed to come of it. If surgeons would use a hypodermic syringe more frequently, they would learn the advantages of it. Dr. Wilson Fox had taught that, after puncture in pleuritic effusions, the serum might be transformed into a purulent liquid. Dr. Barker, however, had seen oftentimes the removal of a small quantity of pleuritic fluid seem to be the first point in the absorption of the rest of the fluid itself.

*Operation for Strangulated Femoral Hernia, in which an Anomalous Obturator Artery was Divided.*—Mr. BARKER read notes of this case. The patient, a woman aged 36, was operated on in the usual way on February 7th. Most of the constricting fibres were easily divided; but, on covering some which remained, embracing the neck closely, blood welled out of the wound. The latter was enlarged and the vessel sought. As it could not be found, and the bleeding soon ceased to be severe, it was deemed advisable to apply pads over the wound, and compress with bandages. On the 8th, the patient was better; and on the 9th better still. Early on the morning of the 10th, however, she took a turn for the worse (indicating peritonitis), and died at 5 P.M. on the same day. A *post mortem* examination revealed acute peritonitis with serous effusion. Near the wound, about three or four ounces of blood were found effused underneath the peritoneum in the pelvis above and to the right side of the bladder. This blood came from an anomalous obturator artery passing down on the inside of the neck of the sac. It sprang from the epigastric about half an inch from its origin, and was completely severed at about three-fifths of an inch from its commencement. Its vein lay to the outside of the sac. The proximal end was plugged; the distal had furnished the bleeding. Mr. Barker remarked that his object in bringing the case before the Society was not only that it was a rare one, but that he hoped to elicit an expression of opinion from the members as to the best mode of dealing with cases where this rare accident had occurred. Was the artery to be sought at all costs, and ligatured; or was it, in certain cases, as in this, to be left to itself controlled by plug? He had, with a good deal of trouble and search through English and Foreign literature, succeeded in collecting only twelve cases where this accident had occurred: excluding doubtful cases where no correct record had been given. Out of these, he said it was remarkable that in six the vessel was secured with ligature or hook, and in six it was left to itself. Of the first six, two died; and of the second six, one (the present case) died of peritonitis. Without desiring to make too much of these facts, he thought that the one line of practice was at all events justified as well as the other, although in some books very positive statements were made as to the urgent necessity of seeking the artery and placing a ligature upon it.

The PRESIDENT said that he personally had only once seen such a case, and that was one of those mentioned by Mr. Barker, which had been under the care of Mr. Stanley. The artery in that instance was tied, and the patient did well. He had encountered hemorrhage in some of his operations for femoral hernia, but had always stopped it by local pressure. When the cases recovered, it was difficult to say whether the blood came from a wounded obturator artery or from a vein. In the six cases of wounded obturator artery which were ligatured, Mr. Barker, who had collected them, had said there were two deaths; that proportion of fatal cases was not much greater than the deaths after ordinary operations for strangulated hernia. He thought each case should stand on its own merits. In some, pressure would suffice; in others, the subcutaneous fat, &c., being pushed aside, the artery might be tied. In some cases, however, it would be very difficult to find it.—Mr. HUTCHINSON thought also that each case should stand on its own merits. In the present case, did Mr. Barker think there was any secondary hemorrhage? If not, the cause of death was evidently peritonitis. What was the method adopted for applying pressure? He advocated the plugging of the wound by a sponge with a silk thread tied around it, dipped in alcohol, and then thrust deeply into the wound, as generally the best method of arresting the hemorrhage. He had had no case of wound of the obturator artery. Possi-

bly, if the patient were thin, the artery might be tied; in other cases, pressure should be applied.—Mr. MAUNDER said he was personally grateful to the author for the valuable information conveyed in his paper. Hunting up statistics was always more or less irksome and distasteful; but Mr. Barker had done this very efficiently, and had clearly indicated the line of treatment to be adopted. Doubtless, an individual case must be treated on its own merits, and, in an instance of severe hemorrhage, the bleeding vessel might be sought for. Failing to find this, compression must be resorted to, and, in order that it might be effectual, the compressing body should be applied through the wound and upon the actual source of the bleeding. In the author's case, the patient being stout, and the mode of compression being indirect, all the soft parts of the region intervening, pressure had probably very little to do with the arrest of bleeding; nature proved equal to the emergency.—Mr. BARKER, in reply, said that he had purposely excluded in his statistics all cases in which there was any doubt as to the source of the hemorrhage. In some books, it was emphatically stated that the artery should be ligatured; so said Mr. Hey, Mr. Lawrence, etc. In his own case, at the necropsy, there appeared to have been only a small amount of secondary hemorrhage. The pressure was applied externally, and the wound was not plugged, as the external pressure seemed to be enough.

## CORRESPONDENCE.

### IS ALCOHOL FOOD?

SIR,—Dr. A. Carpenter, in his address on *Alcoholic Drinks* in your last number, says: "Every medical man must have seen cases, which now and then have fallen to my lot to witness, in which life has been prolonged for many months without any other nourishment than that which was contained in the spirituous liquors or wines which the patient would alone consume." If this statement be true, the question which has so long exercised the scientific—viz., Is alcohol food?—needs no further debating; it is manifestly settled, and "drink" certainly scores a most valid argument in its favour. But, as a doubter, would you allow me to ask Dr. A. Carpenter to show his proofs of this important assertion? Before such proofs, I should say it is contrary to all experience and knowledge. So far from cases of the kind being known to all medical men in large practice, I should rather believe, until the contrary is shown, that no medical man can produce such a case. By proof I mean evidence which justifies scientific belief. On the face of it, most rigorous and difficult proof is required to substantiate the statement. A man who can swallow alcoholic drinks can swallow liquid foods, at all events; and how is a medical man to vouch that for months together nothing but alcoholic drinks, sweetened perhaps with a little sugar, have passed down his patient's throat? If the patient be the authority, what, one may fairly ask, is the value of an assertion made by his muddled or drunken wits? What account would Falstaff, after drinking "this intolerable deal of sack" (two gallons) have taken of the halfpennyworth of bread charged in his reckoning? And where, I would ask, are the medical men and attendants who would allow their patient to be supplied for months together with alcoholic drinks unmixed with nourishing food? and what would be the sense of it? I am sure Dr. A. Carpenter has no wish to encourage drinking; but most assuredly the exaltation of alcohol into a food (for what else can it be, if it sustain life "for many months together"?) will not fail to be used as an apology by those who resort to it in excess.—Yours obediently, W. O. MARKHAM.

London, May 18th, 1878.

### FACILITIES FOR CLINICAL SURGERY AT OXFORD.

SIR,—In the article on *University Education*, which appeared in the *BRITISH MEDICAL JOURNAL*, it is stated that, at the time of the visit of your representative, there were only seven cases of accident and operation in this Infirmary. Would you kindly give the date of the visit of your representative? for I feel sure he could not have been correctly informed. He never asked either of the surgeons or myself for any information; we should have been very pleased to have afforded him every facility for carrying out his investigations. I should think he probably mistook the number in one ward for the total number of operations in the Infirmary.

Should you care to have information as to the number and nature of the surgical cases in the Infirmary, I shall be very pleased to send you a list of them.—I remain, your sincerely,

W. LEWIS MORGAN, House-Surgeon.

Radcliffe Infirmary, Oxford, May 21st, 1878.

## DR. FOSTER ON MEDICAL EDUCATION AT CAMBRIDGE.

SIR,—Dr. Foster proposes that the M.D. degree at Cambridge should not be a natural sequence of the M.B., but a title of distinction (such as the F.R.C.S.).

To make such a distinction between the M.D. and M.B. as exists between the F.R.C.S. and M.R.C.S. would be impossible without lowering the M.B. to the level of the M.R.C.S.; for the M.B. degree not only indicates that the graduate has had an university training, but that he has practically appreciated the advantages thus offered, and is a better educated practitioner than he probably would have been had he studied at an ordinary school and contented himself with a mere licence to practise. A general practitioner who merely wants to show that he has been at Cambridge can very well do so by taking the ordinary B.A. degree, and obtaining his licence to practise from one of the metropolitan boards.

It may be well to point out, however, that there is a test distinction between the M.D. and M.B. degrees at Cambridge. The Bachelor of Medicine, in addition to having to wait three years for the doctor's degree, is required to (1) read a thesis; (2) write an *extempore* essay on some subject in Medicine, Pathology, Physiology, or State Medicine; (3) pass an examination in Pathology, Practice of Medicine, and State Medicine.

I always thought that Cambridge could compare favourably with other universities as regards the success of her medical graduates; but Dr. Foster speaks of the comparative professional failure of Cambridge men.

It would be interesting to know whether from the list of failures Dr. Foster makes exceptions of such men as Sir Thomas Watson, Sir George Burrows, Drs. Arthur Farre, Guy, Handfield Jones, Howship Dickinson, Pitman, Herbert Davies, Barclay, Hare, C. A. L. Robertson, Dalby, Galabin, Liveing, Sturges, L. S. Forbes Winslow, G. H. Philipson, W. Ogle, A. Ransome, Clifford Allbutt, and the staff of Addenbrooke's Hospital.—I am, Sir, yours, etc.,

GLYNN WHITTLE, M.A. Cai. Coll. Cantab., M.D. Trin. Coll. Dub.

Parliament Terrace, Liverpool, May 13th, 1878.

\*\*\* We are glad to see that Dr. Foster's proposals are likely to be adequately discussed; but we must hasten to add that the parallel between the proposed M.D. Cantab. and the F.R.C.S. Lond. was our own. The parallel may not have been a very happy one; at any rate, we will give Dr. Foster's own words on the subject without comment or addition:—"The M.B. (as distinguished from the M.D.) might profitably be used to denote, not men of unusual medical ability, but men who, being qualified to practise medicine, had enjoyed the advantages, and presumably manifested the benefits, of an university career." (Page 29.) . . . "In order to afford a wholesome stimulus during one, two, or more years of foreign study, *i.e.*, of study away from Cambridge, the M.D. examination should be made a real and indeed a difficult one, so that the man who wasted this precious time would have to be contented with the lower title of M.B. The M.D. examination might be either general or special, according to the tendencies of the candidates, but should in all cases be thorough, searching, and, above all things, practical. The thesis which at present forms part of this examination might profitably be retained if the useless disputation in the schools were omitted. The title of M.D. should, in fact, be not a natural sequence of the M.B., but one of real distinction only to be gained by men who have devoted themselves with vigour to the study of the profession." (Page 30.)

## OBITUARY.

## HENRY JEPHSON, M.D.

OUR obituary list last week contained the name of one of the most remarkable physicians whom this century has seen. We allude to Henry Jephson, M.D., of Leamington, who died at his residence, Beech Lawn, on May 14th. During the past week, the local as well as the general press has been full of interesting notices of his life, so that our duty might almost be fulfilled if we reproduced some of these; but it will probably interest our readers more if we give a short account of that part of his career more generally interesting to the profession.

Henry Jephson was born on October 4th, 1798, near Mansfield, in Nottinghamshire. As a youth, he showed much interest in scientific studies; and, while experimenting with fulminating silver, he blew off the first and second fingers of the right hand. He has often told friends that much of his subsequent success in life depended upon his know-

ledge of chemistry: a subject not then very much studied or valued by the profession. In after-life, when his marvellous success in practice left him hardly a minute which he might call his own, he had a laboratory in which he occasionally snatched a few hours of relaxation. When quite a youth, he became a pupil of Mr. Alcock, and was entered at St. George's Hospital. Here he made the acquaintance of Mr. Brodie, afterwards Sir Benjamin Brodie, who was house-surgeon there, and the friendship between them continued till Sir Benjamin's death. Mr. Chambers, a retired surgeon of the navy, was then in practice in Leamington, which was a small place of about two thousand inhabitants, but with a rising reputation as a health-resort, on account of its saline springs, which were even then coming into much use. Mr. Chambers required an assistant, and, on applying to Mr. Alcock, young Jephson was strongly recommended by the latter to Mr. Chambers. In 1818, Jephson came to Leamington, and, from that time until his death, he never left it, except temporarily. Very soon after his arrival, the assistant made himself so useful and so necessary, that he was taken into partnership by the principal, and, a few years afterwards, Chambers retired from practice, leaving the whole of it to his partner. The success of the young surgeon now became remarkable, and, seeing his way from the reputation he had already acquired beyond the place he lived in, he determined to fit himself for the highest success attainable. In 1827, he left Leamington, and with his wife (for he had by this time made a prosperous and happy marriage), went to Glasgow, where, after the usual residence, he proceeded to the degree of M.D. at the university of that city.

In 1828, he came back from Glasgow and went to Cheltenham, where it was his intention to reside and practise; but a deputation of his old friends and patients waited on him, requesting him to return to Leamington. This he did, and, upon his return, he most honourably repaid to the gentleman to whom he had sold his former practice the whole of the purchase-money.

From this time forward until 1848, exactly twenty years, he had what probably was, and possibly still is, the most extraordinary success ever achieved by any physician. Patients from all parts of the kingdom, from the colonies, and from the continent of Europe, thronged to Leamington. His time was occupied almost night and day. He received summonses, rare in those days, to all parts of the country for consultations, and he had a specially contrived travelling carriage made for these journeys. The income he made is almost fabulous, and we have reason to know that for several years together it exceeded £20,000, and that it once reached £24,000 in one year. As the result of these labours, his health began to fail in 1846, while, in 1847, he first began to perceive that failure of vision which, in 1848, resulted, in spite of the best of advice from Dalrymple and Sichel, in total blindness. It was attributed to what was then called gouty amaurosis; but it was probably not unconnected with failure of nerve-power, the result of overwork.

Since 1848, he has lived in quiet retirement in the house which he built for himself during his great success. The circumstances which led to the extraordinary success of Dr. Jephson are not likely to recur. The art medical is happily becoming in public estimation less of the art magic which it was fifty years ago. But Jephson was a great man and a great physician. His method with most of his patients showed that he knew what he was about, while his absolute demeanour commanded and enforced an obedience that others failed to obtain. He believed that most of our ailments sprang from bad habits of eating and drinking, so that in almost all cases he insisted upon a rigidly plain diet and abstinence from stimulants. In this he was manifestly before his time, and, had his example been more followed, we should have heard less of homœopathy. He made a very general use of the Leamington waters, both internally and externally, and in this respect it would be well if his example were more generally followed; for the saline springs of Leamington are as efficacious now as they were in his day, and are quite as capable of miraculous cures now as then. He had not much time for reading, but he always tried new remedies as soon as they appeared. Some of his prescriptions came almost into general use, and are even now in much repute. We allude particularly to sulphate of magnesia in small doses, with dilute sulphuric acid, and also to the purgative draught known as "the Broom", which, in Leamington at any rate, is still in common use. To his patients he was intensely autocratic and self-dependent, and many amusing anecdotes are told of him.

No man ever made more true or warm friends, and he made them in shoals. To his friends he was ever kind, sympathetic, and generous. No man in our profession, in provincial practice at least, ever had such honour accorded to him while living. A splendid statue of him was erected thirty years ago, the public gardens were called by his name, and two portraits of him were painted for public use. In person, he

was of middle height, and of very intelligent and pleasing countenance. He had a very large head, and, though this did not appear disproportionate, the size of his hat would astonish anyone who saw it. He was most generous with his wealth, and Leamington has good reason, in her public institutions of all kinds, to remember him with deep gratitude. He was for many years a county magistrate, and in Warwickshire was, apart from his profession, most deservedly admired and esteemed. About a month ago, his increasing weakness, arising from failure of nervous power, probably dependent upon degeneration of the nerve-structure, alarmed his friends. Dr. Quain of Harley Street, Dr. Heslop of Birmingham, and Mr. Kimball of Knowle, Warwickshire, gave every assistance to his local medical friend Dr. Thurstfield of Leamington; but, in spite of all their efforts, he gradually and surely declined, and peacefully entered into his well earned rest on May 14th. Though he has so long lived in retirement, he will be greatly missed, especially by his poorer brethren, to whom his heart and purse were to the last open. His career was singular, almost improbable, and now almost impossible. Had he died thirty years ago, his biography would have appeared in every newspaper in England, and books innumerable would have been written about him. *Sic transit gloria mundi*: better as it is; those of us who knew him in later life saw more of his goodness and generosity, and of the patience with which he bore his awful affliction, than others could previously have seen; and, though he might have had more of the plaudits of the world, he could not have had more of the affection of friends.

He married, in 1826, Anne Eliza, daughter of the Rev. Dr. Geldart, Rector of Kirk Deighton, in Yorkshire, who died in 1874. One child, who died in infancy, was the issue of this marriage. Dr. Jephson was buried quite privately beside his wife in the rural churchyard of Old Milverton, near Leamington, on May 17th, 1878.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Board of Examiners, on May 16th; and, when eligible, will be admitted to the pass-examination.

Messrs. Challoner Clay, M. D'Oyley Gilkes, Augustus P. Hills, Frederick M. G. Smith, Percy H. Gardner, James Anderson, John M. Owen, and J. Winthrop Woodruff (Students of Guy's Hospital); Francis H. M. Burton, Arthur Willis, Arthur E. Root, J. Sidney Hunt, and T. Underwood Gray (St. Bartholomew's); Thomas J. Evans, Eugene A. Laurent, and William C. Adams (University College); John A. Webster and Thomas R. C. Edwards (St. Mary's); Robert E. Kygate and David J. Kygate (London); Robert Taylor (St. Thomas's); and David G. Edwards (Liverpool School).

Fourteen candidates were rejected.

The following gentlemen passed on May 17th.

Messrs. Edgar E. A. Phipps, Henry G. Terry, Lestock W. Cockburn, John M. Nicholl, Thomas P. Taylor, and John A. Gray (St. Bartholomew's); Harold D. Davenport, John Rigley, Frederic W. Pilkington, and Benjamin H. Lane (Guy's); Joseph L. Bousignac (St. Mary's); Josiah Beddow (University College); and Frank Newcombe (Middlesex).

Nine candidates were referred.

The following gentlemen, having undergone the necessary examinations, were admitted members of the College at a meeting of the Court of Examiners, on May 21st.

Barnard, John H., Fulham (Guy's Hospital)  
Biden, William P., Beckham (Charing Cross)  
Blacker, Ernest, Bath (Bristol School)  
Clements, William G., Rochester (Middlesex)  
Corbyn, Frederick H., Cheltenham (King's College)  
Davis, George, Blackheath (Guy's)  
Dowsley, David H., Clifton, Canada West (St. Thomas's)  
Drought, Eugene N., Wichmore Hill (St. Bartholomew's)  
Faulkner, Alexander S., Liverpool (Liverpool School)  
Gosme, William W., Monk-soham, Suffolk (St. Thomas's)  
Hough, Charles H., Cambridge (St. Thomas's)  
Jackson, George H., Liverpool (St. Thomas's)  
Jones, Robert D., Conway (King's College)  
Macdonald, George A., Hull (St. Thomas's)  
McKeough, George F., Chatham, Canada (Toronto School)  
Morton, Augustus E., Ashham (Guy's)  
Parke, Thomas H., Shetfield (Manchester School)  
Pettenger, John H., Manchester (Manchester School)  
Pierce, William S., Sheffield (Leeds School)  
Russell, James W. L., Sheffield (Sheffield School)  
Stein, Charles G., Cape Town (University College)  
Smart, Henry O., Woodwich (Guy's)  
Wade, Henry L., Cheadle (St. Mary's)  
Williams, Dawson, York (University College)

Four candidates were rejected.

The following gentlemen passed on May 22nd.

Ambley, Horace L., Hemel Hempstead (Middlesex)  
Bibby, John, Preston (St. Thomas's)  
Biggs, John M., Dullington, Sussex (University College)

Bousfield, Edward C., Bedford (St. Bartholomew's)  
Copley, William H., Melton Mowbray (University College)  
Cowan, Frederick S., Bath (Guy's)  
Davies, Hugh E., Llandulas, Denbighshire (University College)  
Flower, George J. W., Stafford (Guy's)  
French, Francis N., Over, Cheshire  
Fuller, Leedham H., Bath (King's College)  
Gover, Henry J., Clapham (St. Thomas's)  
Haslam, William F., Reading (St. Thomas's)  
Jackman, George F., Southampton (St. Bartholomew's)  
Jackson, William T., Stoke Newington Road (St. Bartholomew's)  
Kidd, Percy, Blackheath (St. Bartholomew's)  
Newman, Arthur J., Wotton, Herts (Middlesex)  
Walter, William H., Sydenham (St. Bartholomew's)

Six candidates were rejected.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 9th, 1878.

Blackwell, Frederick William, Birmingham  
Good, William Ernest, Dorchester  
Mayne, Walter Furlong, Honiton, Devon  
Mellor, Thomas, Bury, Lancashire  
Mistri, Karasji Hormasji, Bombay  
Thomas, William Frederic, Madras

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 16th, 1878.

Daniels, Edalgi Manekji, Gower Place, W.C.  
Hawkins, Walter Robert Thomas, Bristol  
Nicol, Louis Charles Napoleon, Oxford Road, Ealing

## MEDICAL VACANCIES.

The following vacancies are announced:—

**GLOUCESTER GENERAL INFIRMARY**—Surgeon and Assistant-Surgeon. Applications to be made on or before the 30th instant.

**HAILSHAM UNION**—Medical Officer and Public Vaccinator for the First District. Salary, £58 per annum, and fees. Applications to be made on or before the 27th instant.

**KENT AND CANTERBURY HOSPITAL**—Physician. Applications to be made on or before June 28th.

**LONDON FEVER HOSPITAL**—Resident Medical Officer. Salary, £200 per annum, with residence, coals, gas, and attendance.

**METROPOLITAN FREE HOSPITAL**, Commercial Street, E.—Two House-Surgeons.

**NORTHAMPTON COUNTY LUNATIC ASYLUM**—Medical Superintendent. Salary, £500 per annum, with residence, free of rates and taxes, and £30 for coals. Applications to be made on or before the 29th instant.

**QUEEN'S HOSPITAL**, Birmingham—Resident Surgeon. Salary, £50 per annum, with board and residence. Applications to be made on or before the 31st inst.

**ROYAL HANTS COUNTY HOSPITAL**, Winchester—House-Surgeon and Secretary. Salary, £100 per annum, with board and lodging. Applications to be made on or before the 27th instant.

**SCARBOROUGH DISPENSARY AND ACCIDENT HOSPITAL**—House-Surgeon and Secretary. Salary, £120 per annum. Applications to be made on or before the 30th instant.

**SOMERSET COUNTY LUNATIC ASYLUM**—Assistant Medical Officer. Salary, £120 per annum, with board, residence, and washing.

**WESTMINSTER HOSPITAL**—Resident Obstetric Assistant. Applications to be made on or before the 31st instant.

**YORK FRIENDLY SOCIETIES' MEDICAL ASSOCIATION**—Assistant Medical Officer, from 25 to 35 years of age. Salary, £150 per annum, with fees. Applications to be made on or before June 4th.

## MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

\***BATTERSBURY**, Richard Legg, M.B., appointed Visiting Medical Officer to King's College Convalescent Home, Hemel Hempstead, Herts.

**GLANVILLE**, F. F., M.R.C.S. Eng., appointed House-Surgeon to the Belgrave Hospital for Children.

**MORGAN**, John H., M.A., M.R.C.S., appointed Assistant-Surgeon to the Hospital for Sick Children, Great Ormond Street, vice J. W. Haward, F.R.C.S., resigned.

**MORGAN**, John H., M.A., F.R.C.S., appointed Assistant-Surgeon to the Hospital for Hip-Disease in Childhood, vice H. P. Butlin, L.R.C.P., resigned.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

### BIRTH.

**ROWLAND**.—On May 17th, at Gloucester House, Malvern Wells, the wife of \*H. Mortimer Rowland, M.D., of a son.

### MARRIAGES.

**FRY**—GASKOIN.—On the 16th instant, at the Parish Church, Oystermouth, by the Rev. S. C. Morgan, Vicar of Swansea, R.D., John Farrant Fry, fourth son of the late William Fry, Esq., of Portfield, Somersetshire, to Constance Mary, eldest daughter of John Gaskoin, Esq., of Longfield, Oystermouth, Glamorganshire.

**SHAPLEY**—OVERELL.—On May 16th, at the Parish Church, Leamington, by the Rev. —Richardson, M.A., of St. John's, Leamington, Harry Thomas Shapley, M.B., M.R.C.S., to Eugénie Eliza, youngest daughter of William Overell, Solicitor, Leamington.—No cards.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY ....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**TUESDAY.**—Royal Medical and Chirurgical Society, 8.30 P.M. Sequel to Mr. Barwell's Case of Aneurism of the Aorta, etc., treated by Double Distal Ligature; Dr. Vandyke Carter, "On the Spirillum Fever of Bombay, 1877"; and, if time, "Dr. H. Jones and Mr. H. Page, 'Cases of Intussusception'; Dr. Semon, 'Case of Thyrotoxicity'; Dr. Stephen Mackenzie, 'Fatal Purpura following a Single Dose of Iodide of Potassium'; etc.

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**MR. S. A. MORGAN.**—Looking to recent decisions, we should think that there was very little chance of success in any criminal proceeding; but a civil action for damages on the case stated might succeed, if the facts could be judicially proved.

## THE BUYING OF A PRACTICE.

**SIR.**—I should be very glad to know from those experienced in such matters, if it be generally considered a safe investment to buy a practice?—I am, etc.,  
May 17th, 1878. DOUBTFUL.

## INQUIRY IN CASES OF SUDDEN DEATH.

**SIR.**—Will you favour me with your opinion in the following case? A man aged 66 died quite suddenly, in the presence of several persons. At the inquest, the coroner asked me what was the cause of death. I answered, a sudden arrest of the heart's action, the result of natural causes. The coroner was dissatisfied with my answer, and requested me to say what the sudden arrest was caused by. As there was no *post mortem* examination, I stated it might have resulted from various causes, such as fatty degeneration, embolism, etc., but that no definite cause could be ascertained without an actual inspection of the diseased structure. In your opinion, was my answer correct under the circumstances stated above?—Your obedient servant,  
A COUNTRY SURGEON.

\* \* We doubt even whether the first answer was not in excess of the available knowledge in the absence of the accurate information which an inspection of the organs could alone impart.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

**THE** following were the questions on Anatomy and Physiology submitted at the written examination to the one hundred and thirty candidates for the diploma of membership of the Royal College of Surgeons on the 10th instant, when they were required to answer at least four, including one of the first two, out of the six questions. 1. Describe the structure of the bronchial tubes. What purposes are served by the several tissues which are found in them? 2. What is meant by the vaso-motor centre? Give the evidence of its existence. 3. Describe the articulations and ligaments of the seventh rib, and the attachments of muscles to it. 4. Give the dissection required to expose the gluteal and sciatic arteries outside the pelvis. 5. Describe the course and distribution of the ulnar nerve in the palm, and the dissection necessary to expose it. 6. Describe the entire lacrymal apparatus.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

## THE SPECIAL SERVICE AT ST. PAUL'S CATHEDRAL.

**SIR.**—Will you kindly allow me to direct the attention of your readers to an advertisement which appeared in the last issue of the *BRITISH MEDICAL JOURNAL*, announcing that by the kind permission of the Dean a special service for the medical profession will be held in St. Paul's Cathedral on Friday evening, the 31st instant, at 8 P.M., when a sermon will be preached by the Rev. George Joly? The choral arrangements have been kindly undertaken by the London Gregorian Choral Association, and the choir will number about four hundred men and boys. A special service-book has been published, containing the special hymns, psalms, and lessons which have been selected as most fitting to be used on this occasion. As perhaps the question may be asked why such a service has been organised, let me add that I think there is a special fitness in such a public expression of our opinion of the need which exists for, and the advantages which may result from, a religious service of the kind we hope this will be. What that need is, and what those advantages are, I feel I may safely and wisely leave to the heart and conscience of each of your readers to answer for himself.—Your obedient servant,  
George Street, Hanover Square, May 1878. ALFRED MEADOWS, M.D.

**ERRATUM.**—In the note on a case of poisoning by carbolic acid, published in the *JOURNAL* of the 11th inst. p. 629, instead of "Homerton Small-Pox Hospital", read "Hampstead Small-Pox Hospital".

## NOTICES OF MOTION.

**SIR.**—Will you kindly inform me what steps are necessary to bring before the annual meeting of the Association any motion a member may desire to submit in reference to the time of notice, etc.?—I am, dear sir, yours faithfully,

May 21st, 1878.

BENJAMIN BARROW.

\* \* We have referred this letter to the General Secretary, who informs us that, in the case of the proposed formation or alteration of a by-law, notice in writing must be given to the Committee of Council at least two months previous to the annual meeting (the annual meeting will be held on August 6th next). If the proposed motion do not involve the alteration or formation of a by-law, notice should be given in writing to the Committee of Council on or before the 25th June next.

**A METROPOLITAN TEACHER.**—It is many years since the College of Surgeons required all teachers to undergo an examination as to their capability for imparting instruction. The regulation, however, was soon rescinded. We believe only two gentlemen were examined and approved—viz., Mr. Erasmus Wilson, F.R.S., and Sir Rutherford Alcock.

## THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

**SIR.**—There are many friends of Mr. William Adams who would be glad to vote for him at the Fellows' annual meeting at the College on the 4th July next, and he has been urged to offer himself as a candidate; but as Mr. Gay is a friend and colleague, and as Mr. Adams is afraid that his candidature would imperil the chance of Mr. Gay, Mr. Adams has very generously declined to be nominated, and he hopes that Mr. Gay may be elected to a seat in the Council, for which he is so well qualified.—I am, your obedient servant,  
Redruth, May 21st, 1878. HENRY HARRIES.

## THE DUKE OF RICHMOND'S MEDICAL BILL.

**SIR.**—Having read the leader in the *Times* of the 8th instant on the above Bill, allow me to state, as my determined resolution, that, having several sons, some of whom I am bringing up by a high training for the medical profession, I shall remove them from the schools at which they are as women-students be introduced into those schools, and shall require of any other school or schools to which I may send them an undertaking that no female students shall at any time be admitted, or if so, that the fees paid by me shall be remitted. My resolution is formed in the interest of my sons; and I, as a parent, having to bear the brunt of heavy expense and anxiety, have as just a right to dictate the terms of their association as any clique in or out of Parliament; therefore I would say to the heads of the medical schools—Beware—Yours, etc.,  
PATERFAMILIAS.

## PROFESSIONAL ETHICS.

**SIR.**—Would you kindly express your opinion of the following case? A medical gentleman died some time ago, and his widow conducted the practice, with the aid of an assistant, till a suitable successor was found. A stranger came to the place, and began practice on his own account. After working for a week, he called on the widow, saying that, as he was established, he was prepared to treat with her for the practice "on equal terms", and he accordingly made an offer that was tantamount to an insult. The practice was transferred to myself; and, on my arrival, I found my opponent canvassing the members of the clubs and works which belonged to the original practice, bribing those who were to be bribed with liquor to get them to support him. Not content with this, he also goes about offering to attend midwifery cases for nearly a third less than has been the usual fee here.

These are the plain unvarnished facts of the case, and I am prepared to substantiate them. I ask whether such conduct is professional or gentlemanly, and I also ask whether we are bound tamely to submit to it?—I am, sir, faithfully yours,  
May 1878. M.D.

## FOREIGN DIPLOMAS.

**SIR.**—Under the heading "The Brussels Degree", there is an answer given by your correspondent "Rhys", which is calculated to mislead. The M.D. degree of Brussels or any foreign university would only be recognised under the Medical Act Amendment Bill if the holder were a foreigner or had practised outside the United Kingdom for ten years, just what many of those who take it have not done, and which is evidently not the case your correspondent alludes to, since he speaks of men going to Brussels to get their degree, and also of their being already on the Register in consequence of having British qualifications. Personally, I think it a hardship that Englishmen are thus to be placed in a worse position than foreigners as regards these degrees, and would like to see a provision for giving the title of Doctor to all who passed the conjoint examination, but fear the profession are hardly prepared for that yet. It is worth noticing that of twelve Fellows admitted to the College of Physicians on May 9th, three had German degrees and three Scotch.—Sincerely yours,  
H.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

#### COMPULSORY VACCINATION.

SIR.—The *BRITISH MEDICAL JOURNAL* being recognised as the organ of an association of seven thousand medical men, your offensive comment on Mr. Bright's views on compulsory vaccination cannot be otherwise than distasteful to all men of liberal minds, and is ill calculated to raise our Association in the opinion of the public. You must be aware that what you term "an indulgence to propagate small-pox" is sold daily by the government, with the sanction of the medical profession, but fixed at a price which only the rich can afford, who are allowed to evade vaccination as long as they choose to pay their pound from time to time. Why not cut the matter short by giving the magistrate power to take the child from the mother's arms and have it carried away by the police to be vaccinated? This would be logical, and would be really compulsory, and there would be no sham about it. This is what Mr. Bright recommends, if the government and the doctors can get over the difficulty which this invasion of the sanctity of domestic life would involve. However, even the *BRITISH MEDICAL JOURNAL* will scarcely be strong enough to steer away the reputation of the great orator and statesman who will long live in history as the great tribune of the people.—Your obedient servant.

EWING WHITTLE, M.D., M.R.I.A.

Parliament Terrace, Liverpool, May 21st, 1878.

\* We are somewhat at a loss to understand what our correspondent means; but we believe that Mr. Bright's view on the subject, of allowing vaccination to be evaded by a single payment of a small fine, is a very dangerous view, and that our objection to it is shared very generally by the profession.

#### THE EXAMINATION OF LADY-DOCTORS.

SIR.—May I inquire of the men into whose hands Providence—no doubt for some wise purpose, probably for the punishment of our sins—has delivered the future of the medical profession in Britain, why women are to be subjected to a different examination from that which men must undergo? Surely if these "lady-doctors" of the future are to be entrusted with the care of our wives and daughters, and even of our male children's health, it is the duty of the State to see that they know as much at least as the most ignorant male student who manages to "screw through" his examinations. The indecency of subjecting women to some of the questions which men are expected both to know and answer is, I suppose, the ostensible excuse for the clause in the Government Bill which enacts this wise decree. Now, I submit that delicacy of mind is all very well in a lady so long as she does not step out of her own domain; but when the issues of health and disease, of life and death, are the things with which she deals, such delicacy is misplaced. An examiner may excuse her from an indelicate question; but will disease, the great examiner of us all, be complaisant? The young man, with bodily and mental health ruined, the prey of evil habits, will curse the law which delivered him in his early childhood into the care of a woman who was too delicate-minded to know the evils of phimositis, and the easy method of its cure. How, indeed, can the diseases of the childish genital organs be appreciated by one who knows scantily, or not at all, their physiological purport in the future? And then, no doubt, it would be considered indelicate for an examiner to go thoroughly into and test the knowledge of the candidate in the diseases of the female genital organs. Surely under the present Bill the male examiner would be precluded from shocking the sensibilities of the blushing young surgeon before him by questioning her on Baker Brown's theory of the cause of epilepsy in females, or on the cause of sterility, or on the effects of prostitution, or on many other of those most important subjects the knowledge of which on the part of the candidate would, no doubt, shock her delicate mind, but her ignorance of which will doom a vast number of women to a life of pain, and will wreck the happiness of unnumbered households.

I might carry my argument further, and point out the impossibility of a woman being examined in medical jurisprudence or other important subjects; but I have said enough. I do protest against women being admitted, if admitted they must be, into our profession through a different portal from that through which their male competitors are forced to struggle. Surely it is a burning shame that at the time when examinations are becoming every day more difficult, a flood of ignorant persons should be poured into our body, whose less efficient, and therefore less extensive, education enables them to offer their advice at a cheaper rate than the heavily handicapped male practitioner.

I do trust that our Association will raise its voice against this terrible injustice. I for one protest against the whole Government Bill, as a weak attempt to settle a great question. But against the particular clause to which I would call the attention of the Association I especially object: no body representing the feeling of the profession could have let this clause pass through their hands, modified or unmodified, as the Medical Council have done. Representing as it does, not the sense of our profession, but the crochets of a few court surgeons and physicians, it is indeed time it was reformed, or, still better, entirely swept away.—Yours faithfully,

WILLIAM SYKES.

April 20th, 1878.

#### THE TREATMENT OF NEURALGIA BY TETRACHLORIDE OF CARBON.

SIR.—In your report of the spring meeting of the South Wales and Monmouthshire Branch a slight error occurs, which I am desirous of correcting. I am reported to have read, "Hints on the treatment of neuralgia, mentioning more particularly the hypodermic injection of morphia and the use of the tetrachloride of carbon." Now, although in the course of my paper I referred to the value of the hypodermic method, my object "more particularly" was to draw attention to the local treatment of neuralgia by the application of ether spray and by the tetrachloride of carbon. I should hope that the treatment of neuralgia by morphia hypodermically is too well known to require any "hints" for its use from me; but cases do occasionally occur in which even this sheet-anchor fails, and in such cases I suggested that freezing by ether, or the local application of the tetrachloride of carbon (the latter originally recommended by the late Dr. Kenyon of Harrogate), might be found of service, and referred to a few cases in which one or other of these agents had given relief after the failure even of morphia. I would take this opportunity of describing the method I adopt of applying the tetrachloride of carbon. A piece of lint, or, better still, some sponge-pine, is sprinkled with some twenty or thirty drops of the tetrachloride, and applied lightly over the seat of pain; in a little while, tingling is felt and a sensation of warmth in the part, when the pain is generally relieved. I am, sir, your obedient servant,

J. HANCOCK-WATHEIN.

Fishguard, May 21st, 1878.

#### FIAT EXPERIMENTUM.

MR. HENRY BERGH, an active member of the Society for the Prevention of Cruelty to Animals at New York, a short time ago publicly declared his disbelief in the existence of hydrophobia. With the view of testing the question, a physician of that city, in a letter signed "Rabies," which appeared in the *New York Herald*, offered to deposit the sum of one thousand dollars with the *Herald*, to go to Mr. Bergh's society, if that gentleman would allow himself to be inoculated with the saliva of a rabid dog, and escaped hydrophobia within six months after such inoculation. Mr. Bergh, however, contrary to public expectation, showed no inclination to accept this benevolent offer, and remained silent, not deigning even to answer the challenge. In order, therefore, "to allay popular anxiety on the subject," he was interviewed by a *Herald* reporter, to whom he stated that "he regarded the offer as a mere joke." On being assured that the proposal was made in perfect seriousness, and emanated from "one of the most prominent physicians of New York," Mr. Bergh replied with dignity, "Well, if that be the case, I must say that it was in very bad taste, for he could not have thought that for one thousand dollars I would allow myself to be inoculated with the saliva of a rabid dog. We are not," he added, smiling, "so hard up for money as that." As nothing satisfactory was to be got out of Mr. Bergh, the reporter proceeded to the house of the "eminent physician," whom he found seated in his library, fully bent on inoculating Mr. Bergh, and terribly in earnest on the subject. "You may assure him," said the physician, "that I will perform on him a painless operation, which will give him no bodily suffering. I will put him under ether, or, if he prefer, even under nitrous oxide gas, which destroys all sensibility whatever." On being asked, "Why not operate on a dog?" the eminent physician replied, "Because Mr. Bergh is violently opposed to vivisection, and because I would not do such violence to his feelings as to experiment upon an animal incapable of giving his assent to the operation." He further offered, in the event of Mr. Bergh thinking the amount too small, to increase it considerably if this would induce him to be inoculated. Here, says the *Full Mall Gazette*, the matter rests for the present.

The Antidotal Treatment of Disease. By John Parkin, M.D. London: Hardwicke and Bogue. 1878.

# CLINICAL LECTURE

ON

## THE TREATMENT OF CHRONIC ENDOMETRITIS.

By LOMBE ATTHILL, M.D.,  
Master of the Rotunda Hospitals, Dublin.

I PROPOSE to call your attention to-day, gentlemen, to the subject of chronic endometritis, a disease of very frequent occurrence. It is quite common in married women who are sterile, and is far from being rare even in virgins. It also occurs frequently as a result of imperfect involution of the uterus; and in aggravated cases may terminate in complete disorganisation of the intra-uterine mucous membrane. Such extreme cases are, however, rare.

All cases of chronic endometritis naturally divide themselves into two classes; namely, those which occur in women who have borne children, and those who have never been pregnant. The course, symptoms, and treatment of these two classes are essentially different. I shall first briefly allude to the affection as it occurs in those who have borne children.

In the great majority of such cases, the patient's attention will be attracted to her condition by the occurrence of derangement of the menstrual function, which generally, in the first instance at least, becomes profuse, and often painful; leucorrhœa, too, is generally present. On proceeding to examine the patient, the cervix will be found to be thickened, the os patulous, the lips perhaps everted, and possibly in a state of granular erosion, while a copious discharge, thick, opaque, and tenacious, issues from it; the cervical canal also is patulous, and the sound will pass with ease through the relaxed os internum. Nevertheless, its introduction often causes pain, either at the os internum or when its point reaches the fundus. If the sound cause pain as it passes through the os internum, menstruation is, I believe, always painful; but if the extreme sensitiveness be confined to the fundus, this may not be so. Dr. Routh is of opinion that in some instances that portion of the endometrium situated between the openings of the Fallopian tubes may alone be diseased, and he terms this "fundal endometritis". I much doubt, however, if the affection be ever limited to so circumscribed an area. As the disease progresses, the mucous membrane lining the body of the uterus becomes disorganised. This is manifested, as already pointed out, by derangement of the menstrual function, which becomes painful, or profuse, or both, and it is not till this stage is reached that, as a rule, the patient seeks medical aid; true, she will in general complain of pain in the back, of a feeling of weight in the pelvis, and perhaps of a bearing-down sensation; but when contrasted with the disease as it occurs in the unmarried or sterile woman, endometritis in the woman who has borne children produces comparatively little discomfort, and, except when the patient is run down by profuse or constantly recurring hæmorrhages, comparatively little constitutional disturbance.

Here is a typical case. Mrs. —, aged 25, gave birth to her first and only child three years ago. She nursed but a few months, and then, menstruation recurring normally, she weaned the child. Shortly afterwards, her husband became ill, and for many months she tended him by day and night; notwithstanding which, her general health continued tolerably good, and it was not till after the lapse of quite a year that the occurrence of repeated attacks of profuse menstruation, latterly accompanied by acute pain, compelled her to seek relief. In her case, the os uteri was very patulous, and the cervical canal blocked up by a mass of thick semipurulent mucus. When the point of the sound reached the os internum, she complained of sharp pain. I treated this patient by the application of carbolic acid to the fundus, applying it twice a week for about two months. The first menstrual period after the commencement of this treatment was perfectly painless, but was very profuse, and lasted for seven days; the next was equally painless, and was over in four days. Since then, the function has been perfectly normal, and the uterine catarrh has disappeared.

The treatment just mentioned will often prove efficacious, provided the case be of recent origin; but if it be of long standing, and if copious uterine catarrh or menorrhagia be present, more active treatment is called for, that which I usually adopt being, as you are all aware, the application of nitric acid to the whole of the cavity of the uterus.

In all cases where much tenderness on pressure exists, local blood-letting should first be practised; this is a rule from which I make few

exceptions. Local blood-letting relieves the pain to a considerable degree, and certainly favours the action of other treatment, whether that consist of medicines administered by the mouth or applications made directly to the diseased surface.

Endometritis occurring in virgins, or in women who have never been pregnant, runs a very different course. In the great majority of cases, these will seek medical aid either for the cure of sterility, or, more generally, with the view of procuring relief from the sufferings which they experience at each menstrual period. I will first trace a case as it occurs in a married woman. On being questioned, she will, as a rule, tell you that prior to marriage menstruation had been normal, or at least attended with but little suffering; that, after marriage, the function gradually became more painful, and that this increased in intensity till she was compelled to seek relief. On making a vaginal examination, you will find the cervix uteri to be elongated, probably swollen and congested; frequently too, indeed I think in the majority of cases, antelexion of the fundus will be found to exist, the os uteri is small and annular, and frequently we shall be able to see a clear and slightly viscid discharge to exude from it.

Now, the pathology and causation of these cases is, I think, this. They always occur in women in whom either the cervical canal is contracted and the cervix conical, or in whom some congenital flexion of the uterus exists; the canal, narrow though it be, sufficed before marriage to permit without difficulty the exit of the menstrual discharge, but under the influence of the excitement caused by sexual intercourse, a greater quantity of blood flows towards the uterus and ovaries; the mucous membrane lining the cavity and cervix becomes unduly swollen and vascular, and, as a result, an increased amount of blood is, at the menstrual period, poured out into the cavity of the uterus; the swollen condition of the mucous membrane at the os internum and in the cervical canal renders the originally narrow passage almost impermeable, the menstrual flow is retarded, and, as a result, the blood coagulates in the distended cavity, and thus becomes virtually a foreign body. It excites the uterus to contract; and after much suffering, it is expelled; relief then for a time is obtained, but the same process recurs over and over again, and in time, permanent irritation of the intra-uterine mucous membrane is excited. And now the patient's sufferings are not confined to the menstrual period alone; for, in consequence of the unhealthy condition of the intra-uterine mucous membrane, its secretion is increased in quantity and altered in character; it becomes viscid, and exudes slowly from the uterus. Often its exit is impeded to such a degree that it distends the cavity, inducing permanent dilatation, and often hypertrophy, of the whole organ, aggravating the previously existing irritation of the lining membrane, and causing great distress and pain to the patient.

If these cases be neglected, the whole system suffers: the ovaries are specially liable to be implicated; the irritation set up in the uterus seems to be propagated to them; they become enlarged, painful to the touch, and the source of great suffering; the bladder often sympathises, and the patient suffers from irritability of that viscus; then reflex irritations manifest themselves; the breasts become painful, the appetite fails, and often there is nausea and even vomiting; in a word, chronic endometritis in a nulliparous woman is a most serious affection, causing great suffering and undermining health, not rapidly indeed, but surely, while sterility is an invariable result. Unfortunately, too, it is a most obstinate affection. If the case be of old standing, the hope of doing much for the patient is but small; if, however, it have not gone on too long, the prospect of effecting a cure is good; but to do this, it is essential to bear in mind the pathology of the disease, the basis of which is that the conical cervix and contracted canal, coupled with antelexion when it exists, prevent the menstrual discharges and viscid secretions of the diseased lining membrane from obtaining easy exit. The first step, then, towards effecting a cure is to ensure the free escape of the contents of the uterus. There is but one means of effecting this—the cervical canal must be divided. I lay this down as an axiom from which there are few exceptions, that it is almost impossible to cure chronic endometritis in the nulliparous female in whom a conical cervix and contracted cervical exists, unless the cervix be divided. I have tried every other possible method, including the free use of nitric acid after dilatation of the cervical canal, to find my patient, after the lapse of a few months, in no way improved. The following affords a striking example of this. It is interesting, too, from the fact of its being the first case in which I divided the cervix for the cure of endometritis, my previous operations having always been for the relief of painful menstruation.

Mrs. —, aged 36, married ten years, came under my care four years ago. She stated that, previously to marriage, she had always enjoyed good health, but that, some months subsequently, she suffered from a severe attack of pain in the region of the uterus. This after a

time subsided; but from that date she never was perfectly free from suffering, till of late, though naturally of very active habits, she had been compelled to give up taking exercise nearly altogether; for years, too, she had been off and on under medical treatment, without even obtaining permanent benefit. She suffered from constant headaches (these occasionally were very severe), from indigestion, flatulence, and constipation. She was unable to walk; for, on attempting to do so, she was always seized with pain, referred to a point corresponding to the fundus of the uterus. This pain lasted for some time, then she would obtain relief; and immediately after, invariably perceived a copious viscid discharge to exude from the vagina. These attacks of pain and subsequent leucorrhoeal discharge occurred even when she remained quiet; though then the intervals between them were considerable. Walking, however, always brought them on. I subsequently satisfied myself that these attacks of pain were due to the efforts of the uterus to expel the copious secretion which collected in it.

On making a vaginal examination, I found that the cervix was conical, and the os so small that I could not introduce an ordinary sound, but had to use a fine probe; the fundus was large and heavy, and slightly painful to the touch; there was no abrasion; but, though pressure with the fingers on the fundus caused but little pain, sexual intercourse was always productive of suffering.

I decided on treating this case by applying nitric acid to the fundus, but as this was impossible in the contracted state of the cervical canal, I introduced a length of No. 3 sea-tangle bougie into uterus, and after the lapse of twenty-four hours was, on withdrawing it, enabled to introduce a platinum cannula, and through it apply the fuming nitric acid. The result was for the time very satisfactory. She improved wonderfully, and lost most of her distressing symptoms, and I saw no more of her for four months, when she again consulted me, saying that she was as bad as ever; and, on making a vaginal examination, I found that she had relapsed into her former condition—the os uteri was as small and the catarrh as copious as ever. On considering this case, I became convinced that till I gave free exit to the pent-up viscid discharge no permanent benefit would follow; and believing that division of the cervix would alone effect this, proposed the operation to her. She at once agreed to submit to it, and I accordingly performed it, dividing the cervix bilaterally, in the manner described in a previous lecture. The result has been most satisfactory. She recovered without any drawback, has ever since steadily improved, and now, after the lapse of several years, is quite free from suffering, is able to take long walks, and leads a most active life.

After the divided surfaces have healed, and that no danger of exciting inflammation exists, it is generally necessary to apply carbolic acid, or some other caustic, up to the fundus; in fact, I always keep the patient under observation for some weeks subsequent to the operation. The length of time during which it is necessary subsequently to continue intra-uterine medication must depend on the previous duration of the disease, as well as on the severity of the symptoms. In the case just related, I applied carbolic acid several times to the fundus subsequent to the operation.

In this case, the patient has remained sterile; indeed, I had no hope that conception would follow in her on the cure of the endometritis; the disease was of too long standing. As a rule, I object to perform the operation of dividing the cervix, simply with the view of removing sterility; conception doubtless sometimes does occur after the operation, not because the cervix is rendered patulous, but because the membrane lining the interior of the uterus being rendered healthy, conception becomes possible. The following case is an example of this.

Mrs. K., aged 26, had resided in India, and ever since her marriage, five years ago, has never become pregnant. Menstruation was normal and nearly painless. She suffers, however, constantly from backache and much discomfort in the left ovarian region; is quite unable to take exercise, as walking brings on pain. She was specially anxious to have a family, and returned from India, and sought advice, more with the view of having sterility removed than for the relief of her sufferings. On examining her, I found the cervix to be conical, and the fundus acutely anteverted; there was also a good deal of uterine catarrh. The probe passed to the depth of nearly three inches. As this case was by no means a severe one, and evidently not of long standing, I decided on endeavouring to avoid dividing the cervix, and accordingly introduced an anteversion pessary, punctured the cervix, applied carbolic acid to the fundus, gave bromide of potassium in full dose, and found the patient's condition steadily to improve. All her symptoms subsided; the flexion, however, remained unaltered. After a time, I sent her to Ems, where she remained for some weeks, and returned in a very satisfactory state. Her husband, who during this time had remained in India, now joined her, and they travelled about for a couple of months. On returning to Dublin, just a month before they were to start for India,

she called on me and said she had again of late begun to suffer as much as ever, and on examining her I found her to be in exactly the same condition as when I had first seen her five months before. I at once told her that all she had done had been useless, and that there was no chance of a cure except she submitted to have the cervix divided. She readily consented. I divided the posterior wall of the cervix only, this being the operation I always perform in cases of anteversion. She sailed for India in four weeks from the date of the operation, soon after became pregnant, went to the full term of utero-gestation, and gave birth to a healthy child.

I have given these two cases in detail, because they show how useless any attempt to cure endometritis in sterile women is, unless, as a preliminary step, free exit be afforded to the discharge which invariably collects to a greater or less extent in the cavity of the uterus. And if I have succeeded in impressing this fact on your minds, your failures in your future practice will be lessened very considerably.

## ON THE CURE OF DYSMENORRHOEA, STERILITY, AND CERTAIN AFFECTIONS OF THE UTERUS, BY A NEW FORM OF ELASTIC INTRA-UTERINE STEM.

BY ROBERT GREENHALGH, M.D.,

Formerly Physician-Accoucheur to, and Lecturer on the Diseases of Women and Children at, St. Bartholomew's Hospital; Consulting Physician to the City of London Lying-in and Samaritan Hospitals; etc.

THERE is great difference of opinion among gynaecologists as to the utility and safety of intra-uterine stems—a difference made manifest in a recent discussion at the Obstetrical Society. Notwithstanding the very adverse opinions as to the use of these stems expressed at this discussion, I am convinced that there is an increasing tendency to employ them, as exemplified in the many modifications which have been made in their construction since the year 1844, when they were first introduced to the notice of the profession by Sir James Simpson, and by the large number of these instruments sold by the instrument-makers to practitioners specially engaged in the treatment of the diseases of women. For my own part, being at a loss to imagine how certain mechanical affections of the uterus can be otherwise satisfactorily treated, I am constrained to assume the necessity of some such contrivance.

Before I describe my thoroughly efficient intra-uterine stem, the outcome of many failures and partial successes, it may be interesting to many little conversant with this subject to take a cursory glance at some of the steps which led to the adoption of intra-uterine stems. It is recorded that Aëtius recognised a contracted os uteri as a cause of sterility, and he is supposed to have treated this strictured condition with sponge-tents; but, passing over the dim records of ancient surgery, we come in recent times to the late Dr. Mackintosh of Edinburgh. This acute observer, in the second volume of his work on the *Practice of Medicine*, gives a graphic account of the sufferings wrought by persistent dysmenorrhoea, sets forth the insufficiency of all methods hitherto devised for its cure, and then makes the remarkable suggestion that many cases of painful menstruation might be due to some obstruction, for which condition "mechanical dilatation appeared to be the only remedy". For some years he hesitated to carry this conception into execution. At length, in the year 1826, he put his idea to the test, with such success that he was emboldened to repeat the experiment in numerous cases. In the year 1836, he thus records his experience: "In twenty-seven women, twenty-four cures have taken place, and of these eleven have since had children": an amount of success never since exceeded, if equalled. "The instruments employed to produce the dilatation were the common metallic bougies, of different sizes, from that of the ordinary small silver probe to No. 14." During the year 1844, Sir James Simpson published in the *Edinburgh Medical Journal* (page 734) an account of his permanent metallic stems of various sizes, which, he stated, "gave much less pain to the patients, and less trouble to the practitioner; were more certain and expeditious in their effects". He further stated "that he found the stricture occasionally at the os internum or opening between the cavities of the cervix and body, and not at the os tincte": a statement the correctness of which I, in common with other observers, have since fully verified. In fact, the obstruction in the majority of cases is situated nearer the os internum. In cases where the external os uteri is small, particularly where the neck is conical and elongated, with a canal scarcely admitting the introduction of an ordinary sound, the menstrual flow scanty and of short duration, mostly indicative of

faulty development, leading to dysmenorrhœa or sterility, little or no good is to be expected either from purely mechanical treatment or from incision. The use of the jointed galvanic stem is indicated in cases like this, and in many instances it has proved most useful.

For some time I used Sir James Simpson's stems with considerable success; but, finding they were apt to become corroded and to slip out and to impede the escape of the secretions from the interior of the uterus, I devised, about the year 1862, stems made of vulcanite with numerous perforations. These stems, lighter and less liable to be misplaced, less liable to corrosion, permitted a readier escape of the secretions. I further modified them by reducing the size of the bulb, substituting for it a flat oblong shield. Finding, however, that these forms of stem are liable every now and then to become misplaced, I contrived a metallic expanding stem, which I ultimately discarded for one of vulcanite. A figure of this vulcanite stem, which now I use only after the division of the cervix uteri by the metrotoime, will be found at page 404 of Dr. Marion Sims's *Clinical Notes on Uterine Surgery*. The advantages I claim for this form of stem are, ease of introduction; by its expanding limbs, pressure is made upon the cut surfaces, whereby bleeding is prevented; being perforated through the centre, a ready exit of the secretions is permitted; it is not liable to be misplaced; it can be retained until the healing process is complete; by it, all exposure and frequent painful and irritating dressings of the parts are avoided; and, lastly, being made of unabsorbent material, little or no risk from septicæmia is incurred.

In the year 1844, Sir James Simpson described the operation of division by a "lithotome caché" of any fibres that may be causing contraction of the internal orifice; "the incision commencing at the union of the cervix with the body of the uterus, and passing gradually more and more into the substance of the cervix. As it descends, the blade is brought out at the outer and lower edge of the cervix at the point of reflexion of the mucous membrane upon the wall of the vagina. The instrument is then turned, and a similar cut made on the other side." A short experience of this instrument, although used with the greatest care, convinced me of the uncertainty of its action.

In 1862, Messrs. Weiss and Son, at my suggestion, made at first a curved, and subsequently a straight, double-bladed metrotoime, which can be used without the speculum, can be regulated with the nicest accuracy, and by which both incisions can be completed simultaneously. This instrument has been objected to by a recent critic on account of its "automatic machinery"; and he erroneously remarks that the blades spring out one on each side and make their incisions whilst the instrument is being withdrawn; whereas the blades are

Fig. 1.—Metrotoime.

made gradually to protrude by gentle traction on the handle, gradually cutting through to a small extent the internal os; the cuts increasing in depth through the cervix and external os uteri nearly up to the junction of the neck with the vaginal walls. The blades are retained *in situ* by the sheath while regulating the position of the uterus and the directions of the incisions until the completion of the operation. The extent of the incisions can be regulated with the greatest precision by the adjustment of the blades, which are quite independent of each other. Those who have had experience in its use can testify to the accuracy of this description of my metrotoime. (Fig. 1.)

In addition to these advantages, this instrument secures rapidity of action, and avoids exposure by the speculum and injury to the parts: important points these, especially where the operation is needed on an unmarried woman.

To the fear expressed by the same critic that hæmorrhage and septicæmia are likely to result from this operation, I have to answer that, among a large number of operations, although no plugging was had recourse to, in four cases only did hæmorrhage occur, which was speedily arrested by tannin and the plug; that not a single case of septicæmia resulted; and only one death ensued, in the case of extreme ante-flexion in my early experience of the metrotoime, in a patient who succumbed to tubercular peritonitis, from which she had previously suffered. This case I reported in an early volume of the *Obstetrical Transactions*. All the patients were greatly benefited, the large majority cured; and many, who for several years had been sterile, have since borne children. This form of metrotoime I still occasionally use.

Dilators of various kinds, resembling the sound, and capable of

expansion after introduction within the canal of the cervix, have been used by many practitioners to stretch the canal at any part of its course, though the instruments I have seen seem adequate to dilate only the two distal thirds of the canal. Dr. Priestley's dilator, described in the *Medical Times and Gazette* for March 1864, is perhaps the best; but a fair trial of it has convinced me that such contrivances have little or no advantages over the metallic bougies recommended by Dr. Mackintosh. The sponge and sea-tangle tents, perforated throughout and shortened, have not answered my expectations, since they frequently occasion much pain during the process of swelling, and have every now and then produced so much irritation as to lead occasionally to metritis and pelvic inflammation and abscess. There can be no doubt, however, that each method, when cautiously used in well-selected cases, has sometimes proved effective, though not to an extent to justify us in placing a large amount of confidence in its results.

Often disappointed by all the aids just referred to, and by the modifications of stem recommended by others, and, as experience extended, becoming more and more impressed with the necessity for mechanical treatment, I devised in the year 1872 an India-rubber stem, at first solid and subsequently tubular, armed near the end with two wings, between which was an oval opening in the long axis similar to the end of Mr. B. Holt's catheter. This form of stem I used over a considerable period in numerous cases, and found it a great improvement upon the other forms. Being of softer material, it adapted itself better to the canal, was less liable to slip out or to inflict injury, and could be used without interfering with the marital relation. Finding, however, that the wings added to its size and to the difficulty of introduction, and that when *in situ* they failed to expand in the body of the uterus as I had anticipated, that they occasionally became detached, and that the opening frequently got blocked by the secretions, I sought to overcome these disadvantages. Two years ago, I succeeded in designing a stem with manifest advantages over every other pattern. The stem consists of pure India-rubber tubing, No. 13 catheter gauge, easily admitting the introduction of a large Simpson's sound, two inches and one-eighth in length, tapering at its upper or uterine end, and armed with an oblong shield measuring one inch and three-quarters from side to side and one inch and a quarter from back to front. In this shield are ten perforations to facilitate cleanliness. Three-sixteenths of an inch from its upper extremity is a bulb two inches in circumference, with four diamond-shaped slits, which collapse when stretched on a dilator to facilitate introduction. When the stem is inserted and its retention is secured, and the dilator removed, this bulb at once expands in the body of the womb, while permitting a ready escape of the uterine

secretion. The whole being cast in one piece, there is no chance of the separation of any part of it. (Fig. 2.)

There are two points in connection with the use of the India-rubber stem to which I am particularly anxious to direct attention, in addition to the advantages already referred to. Firstly, although soft, elastic, and easily bent while out of the uterus, it becomes sufficiently firm

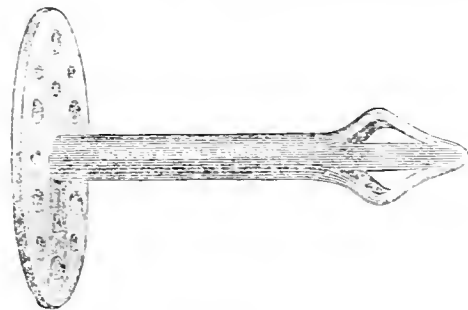

Fig. 2.—Stem.

when pressed equally on all sides by the canal of the cervix to gradually overcome all flexions, except in cases where the uterus is bound down to the surrounding parts. Secondly, its action is not purely mechanical. It has been observed by myself and others that, in many cases where the stem has been worn for some time, the enlarged and

firm uterus has become greatly reduced in size, and so soft as closely to resemble that organ in the early stage of subinvolution: effects probably due to the freer exit of the secretions and the mucous discharge, which usually persists during the retention of the stem.

Having described the form of stem, I shall now briefly allude to the cases in which I have found it most useful; premising, however, that mechanical treatment should never be undertaken till the removal of all indications of active disease, and the uterus is reduced to a minimum of sensitiveness by the use of rest, local depletion, hot vaginal injections, soothing suppositories, and other measures; and, further, until the sound has been passed once or oftener to ascertain how far the uterus is tolerant of local interference. Moreover, at the commencement of treatment, I usually enjoin one or more days' rest in bed. After this preliminary treatment, I first introduce a small silver stem; and in two or three days, if loose, I substitute one of larger size, when the canal is usually sufficiently dilated to admit the introduction of the India-rubber stem. By this gradual dilatation, which occupies usually about a week, the largest stem can be more easily introduced, and far less irritation is likely to follow than when the introduction is more speedily effected—an operation frequently not easy and occasionally impossible.

Should the stem have a tendency to slip out, which is sometimes the case, it can be easily retained *in situ* by pressing upon the shield a plug of cotton-wool, saturated with glycerine, tied crosswise with fine twine to facilitate removal.

I may here remark that early experience taught me never to use sponge or sea-tangle tents, nor dilators, with a view to more rapid dilatation, by which considerable pain is occasioned, and irritation, and sometimes inflammation, is set up, thereby rendering the case temporarily unfit for the stem-treatment.

The most fitting time to introduce the stem is shortly after a menstrual period, its retention being determined by the peculiarities of each individual case, the effects produced, and the end to be obtained. In my cases, the time varied from fourteen days to eleven months. The best time for removal is about a week before the next expected period. When retained for a considerable time, the discharges are apt to become offensive, notwithstanding the daily use of the vaginal douche. Still I have never known any evil result beyond this temporary annoyance to the patient.

I have now used the India-rubber stem for more than four years in a large number of private and hospital cases, and in two cases only—cases of chronic metritis with retroflexion, in which a spring vaginal pessary was worn—have I had to withdraw it on account of the onset of irritation. Both patients were highly sensitive women, and had undergone but little previous treatment. I have found these stems most useful in the following cases:

1. Dysmenorrhœa;
2. Flexions—ante- and retro-flexion of the uterus;
3. Strictures of the orifices and canal of the cervix;
4. Sterility, congenital and induced;
5. Certain cases of subinvolution;
6. Certain cases of interstitial fibroid of the uterus.

The following cases, sketched in outline, may serve as illustrations of stem-treatment.

CASE I. *Congenital Dysmenorrhœa: Sterility: Cure.*—Mrs. A., about thirty years of age, married about five years, always suffered more or less severely from paroxysmal pain a day or two before and during the menstrual flow, which was scanty and clotted. Her sufferings of late had become greatly aggravated, so as materially to affect her general health, and lead her medical attendants to fear the development of phthisis, to which she was strongly predisposed. The uterus was found slightly prolapsed and anteverted, congested and very sensitive, with a copious muco-purulent discharge. In spite of protracted general and local treatment, the dysmenorrhœa still persisted. The sound passed easily with but little discomfort three inches and a quarter into an enlarged cavity, doubtless due to distension by coagula, the expulsion of which gave rise to the pain and kept up local irritation. The stem-treatment was now adopted with marked improvement to both general and local symptoms. At the end of three months, Dr. Hohart of Cork removed the India-rubber stem, and soon afterwards she became pregnant, went to the full period, and was delivered, after a somewhat protracted labour, of a fine child. About a year after, she gave birth to a second child, and when last I saw her she was about two months advanced in her third pregnancy, and was enjoying very fair health.

CASE II. *Congenital Dysmenorrhœa: Extreme Antelexion: Cure.*—I was requested by Dr. Baldock to visit Mrs. P., aged 22, married six weeks, for severe dysmenorrhœa, which had caused her more or less

suffering since the commencement of menstruation, seven years before. Of late, her sufferings had become so agonising as to require, in addition to other means, the frequent use of hypodermic injections of morphia. Her general health had become greatly impaired, and she was almost constantly confined to bed. The uterus was considerably enlarged, was much congested, exquisitely tender to the touch, and acutely antelexed, the fundus being somewhat beneath the level of the cervix uteri, which was directed downwards and forwards. The sound was passed, with much difficulty and pain, three inches and a quarter into an enlarged uterine cavity, when it was found the womb could be straightened. Its withdrawal was followed by a copious discharge of pent-up blood and mucus. In spite of absolute rest, careful dieting, good nursing, hot hip-baths, vaginal injections and suppositories, depletions from the uterus, and other means, carefully carried on for many weeks, her symptoms, general and local, became more and more aggravated, when my advice was again sought. Notwithstanding the unfavourable nature of the case for mechanical treatment, it was resolved to put it to the test. A small silver stem was introduced, then a larger and a larger, and ultimately the India-rubber stem was passed. Dr. Baldock wrote to me some weeks afterwards: "There was first a good deal of pain and discharge, which gradually subsided, and a good period followed." He adds: "The uterus is not quite in a normal position, but very considerably different to what it was. The case may certainly be given in support of the use of stems in uterine flexion."

CASE III. *Congenital Dysmenorrhœa: Menorrhagia: Extreme Antelexion: Cure.*—Miss —, about twenty years of age, had always suffered more or less pain, with a somewhat free loss at her menstrual periods, which commenced about six years ago. These symptoms had much increased of late, together with pains more or less constant in and about her hips, at times extending down the thighs, which had prevented her taking exercise, and led to great impairment of her general health. She was much troubled with leucorrhœa. As a local examination was strongly objected to, she was requested to rest almost constantly upon a tilted couch, to remain in bed during her periods, to use a hot vaginal douche night and morning, and to adopt such means and take such remedies as were calculated to alleviate her pain, moderate the losses, keep the bowels and secretions in order, and improve her general powers. After many months of such treatment, she appeared greatly improved in every respect; but as soon as she began again to move about all her symptoms returned. An examination was now permitted, when the uterus was found considerably enlarged and firm, thrown far back in the pelvis, and acutely antelexed. With some difficulty and pain, the sound, considerably bent, was passed three inches and a quarter into the enlarged body, when it was ascertained that the organ could be replaced. The graduated stems, and subsequently the India-rubber stem, were introduced and worn for some months. Five months after all treatment had been discontinued, I received a most grateful note from my patient, in which she stated: "I have been presented. I have also been to several balls, at one of which I danced fourteen times; and in spite of all this I am perfectly well—better than I have been for more than six years."

CASE IV. *Congenital Dysmenorrhœa: Extreme Antelexion: Sterility: Cure.*—Mrs. B., aged 39, married eleven years, had always suffered from pain at her menstrual periods, and now of late it had become "agonising", usually coming on some hours before the flow, which had varied much from scanty to profuse, so as seriously to impair her health. The uterus was low, congested, tender, and acutely antelexed, the fundus being below the level of the cervix. After some preliminary general and local treatment, the sound was passed with extreme difficulty three inches and a half into an enlarged cavity. Its introduction was followed by vomiting, fainting, and severe pain, which, however, gradually subsided when a small silver stem was introduced, followed in a few days by one of larger size, and subsequently by the India-rubber stem. This stem was worn three months, and when withdrawn the uterus was found healthy and in its normal position. After some months, she became pregnant. Mr. Bateman of Richmond delivered her of her first child in her forty-first year. She has since enjoyed good health.

CASE V. *Induced Dysmenorrhœa: Retroflexion: Cure.*—Mrs. C., aged 32, since her marriage two years ago had suffered severely at her periods, which had always been slight, and had now become "intolerable", occasioning great functional derangement of her digestive and nervous systems. "I am", she wrote "a martyr to neuralgia at those times; cannot sleep, and vomit everything I take." The uterus was highly congested, exquisitely tender, and retroflexed. Her health was much improved by general and local treatment, when my spring-pessary was introduced without effecting any material improvement in the position of the organ, and with no relief to her sufferings. The stem-treatment was now resorted to, and carried out over a period of

five months, with the ultimate cure of her local affection and restoration to health.

**CASE VI. Stricture of Internal Os Uteri: Sterility: Cure.**—Mrs. D., one of eleven children, aged 28, had been married five years. Her husband, aged 32, was one of seven children. She enjoyed good health; menstruated every three weeks and three days, the flow lasting four days, moderate in quantity, bright without coagula; it was accompanied by slight local discomfort. There was no constitutional disturbance. The uterus was normal in position and texture; the external os was round and of average size. The sound passed with ease up to the internal os, where it was arrested. Failing on two occasions to overcome the obstacle, I advised the use of the hot vaginal douche, and belladonna suppositories night and morning. After this treatment, I succeeded in passing a small whalebone sound two inches and a half, for which, on withdrawal, I substituted a very small silver stem, soon to be followed by a larger one, which she wore several days. Then the India-rubber stem was introduced and retained for about five months, with little discomfort but great increase to the menstrual flow. Scarcely six months had passed, when she became pregnant, went to the full period, and was safely delivered of a fine child. She has since had excellent health.

**CASE VII. Congenital Sterility: Cure.**—Mrs. E., aged 28, one of six children, married six years, was well developed. Her husband, aged 29, was one of four children. She enjoyed good health, menstruated normally, and had no detectable disease of the uterus or of the ovaries. The uterus appeared somewhat small and flaccid; but a sound passed two inches and a half easily without pain. She wore for two months an India-rubber stem with slight discomfort and with increase to the menstrual flow, after which the uterus was found somewhat larger and firmer. Two months after the removal of the stem, she became pregnant, and passed satisfactorily through a normal labour at term.

**CASE VIII. Induced Sterility: Cure.**—Mrs. D., aged 36, had two children within two years of marriage, the last eight years ago. She had good labours and recoveries. The uterus was somewhat congested and low in the pelvis. Cured by ordinary treatment. Not becoming pregnant during the succeeding eighteen months, she again applied for advice on the score of sterility. No disease being detected, the stem treatment was adopted. At the end of three weeks, the stem was forced out during a period, which was shortly followed by pregnancy, terminating normally at term in the birth of twins.

**CASE IX. Subinvolution: Sterility: Cure.**—Mrs. T., aged 38, had one child twelve years ago, a year after marriage, severe labour, fair recovery; but since then menstruation had been irregular, usually deferred and scanty, with slight discomfort. General health good. The uterus was enlarged and indurated, low in the pelvis; the os was transverse and patulous, exuding tenacious mucus; the cervix was abraded. The sound passed three inches in the normal direction with some difficulty and pain through the strictured internal os. Under the influence of rest, local puncturing, iodised cotton and glycerine, and the hot vaginal douche, the uterus was brought into a normal state. More than a year having passed without pregnancy resulting, she again applied for advice, when a succession of stems were introduced, and worn for a period of four months with great increase in the menstrual secretion. She became pregnant immediately on the removal of the stem, went to the full period, and was favourably delivered of a fine child. A period of nearly three years elapsed, when she again sought my advice, was similarly treated, and with like successful results, giving birth to her third child in her forty-second year.

**CASE X. Fibroid in Anterior Wall of Uterus: Dysmenorrhœa: Sterility: Cure.**—Mrs. G., aged 31, married upwards of five years, had suffered for many months from profuse and protracted menstruation with intense dysmenorrhœa, producing serious derangement of her health. The uterus was enlarged and firm, much antelexed. A fibroid tumour, about the size of a small walnut, could be detected at the junction of the neck with the body of the uterus. The sound passed three inches and a half with great difficulty and pain through the internal os uteri. As little or no improvement took place in her general or local conditions after many months of treatment, I commenced the use of the stems, which shortly lessened and ultimately removed all pain and greatly moderated the hamorrhages. She wore the India-rubber stem for seven months. About eight months after its withdrawal, she became pregnant. During her pregnancy, the tumour could scarcely be detected. She went to the full period, and was delivered, after a somewhat protracted labour, by Mr. Pocklington, with the forceps, of a living child. She has since, I am informed, made a perfect recovery.

**CASE XI. Fibroid of Uterus: Dysmenorrhœa: Menorrhagia: Cure.**

—Miss H., aged 36, had enjoyed good health till eighteen months ago, when she began to suffer from more profuse, prolonged, and oft-repeated losses of clotted blood, accompanied with severe periodic pains, symptoms which had of late greatly increased and made "sad inroads" on her general health. The uterus was much enlarged, very dense, with nodular deposits about the lower segment of the body. The sound passed with some difficulty and slight pain through the internal os four inches and a quarter into an enlarged cavity. As all remedies, both general and local, had failed to do more than temporarily ameliorate her symptoms, the stem-treatment was adopted with speedy good results. After wearing the stem five months, it was removed, and shortly after her former symptoms began to recur. Again the stem was introduced, and worn for eleven months, since which, upwards of two years, she has menstruated normally. She is now in excellent health, and no trace of the former mischief can be detected.

In two cases, the antelexion was so extreme that, although the India-rubber stems were worn for many months, still they were found bent. In one, the patient was free from dysmenorrhœa at the end of many months, and may still so remain for aught I know.\* As to the other, a hospital patient, from whom Dr. Godson removed the stem, I have no particulars. I have reason to believe, from a subsequent examination, that in one of these cases the uterus was bound down by adhesions to the surrounding parts. In a few cases, where there had been a tendency to a free loss during menstruation, the flow was much increased and the period prolonged, but never to the extent of inducing me to suspend treatment. In nearly all the cases, while the stem was in position, there was a more or less free secretion of mucus, in a few occasionally tinged with blood, which ceased on removal of the stem. I could have largely added to the number of cases treated during a period of nearly five years; but I have deemed it more useful and instructive to restrict myself to the narration of a few typical cases.

A friend, after having read through this paper, remarked that it would be as well to record one or more unsuccessful cases; but, as not one case of failure has at present come to my knowledge in which the stem-treatment has been carried out, I am, happily, unable to comply with his suggestion.

## ON HEMI-ANÆSTHESIA OF SPECIAL AND GENERAL SENSATION.

By W. ALLEN STURGE, M.D.,

Assistant-Physician to the Royal Free Hospital; Physician to the Royal Infirmary for Children and Women.

Now that attention has been frequently and strongly called to the anæsthetic phenomena of hysteria, it may be of some service to examine into the question of hemianæsthesia from whatever cause, and to compare other varieties of this condition with that due to hysteria.

I think it unnecessary to occupy time with arguments to prove the authenticity of the phenomena in question, and to show that they are not the result of "expectant attention or duplicity". It is only surprising that any prominent member of the profession should still be found to maintain such a position in public speaking and in print. I leave all such to settle their account with Professor Charcot, than whom no calmer or more dispassionate observer could be found, and I would refer them to the first volume of his published *Lectures on the Diseases of the Nervous System*.

Besides hysterical anæsthesia, a loss of sensation of the same order has been described in two conditions: 1. Chronic alcoholism; 2. Organic brain-disease. To these I would add a third condition—viz., lead-poisoning; and I will begin by narrating a case of this description which came under my own observation in Paris. The hemianæsthesia from alcohol and from lead-poisoning appears to be closely allied to the analogous condition in hysteria; because it is not apparently due to any gross lesion of the brain, and may therefore be classed with the so-called functional modifications of sensation; and because, in many cases of the alcoholic form at least, the recovery was rapid and complete.

**CASE I.**—P. L., male, aged 52, was admitted into l'Hôpital Temporaire, under the care of M. Lépine, on May 18th, 1877. From twenty to thirty-four years of age he had been a soldier. He denied syphilis. After leaving the army, he worked as a jeweller, and had nothing to do with lead; but, about six months ago, he began to work in some white lead works. At the end of seven weeks, he had a severe attack of

\* I have recently heard that this lady became pregnant, went the full period, and was safely delivered of a living female child about two years ago.

colic, for which he went to a hospital and was an in-patient for three weeks, when he went out cured. He returned to his work, and three or four days afterwards perceived that he was a little weak in the left arm and leg. He suffered at the same time from headache, and he himself noticed that the sensibility of the left half of the body was diminished, and he complained of itching and tingling of the hand and foot of that side. For a short time before this, while he was in hospital with colic, he experienced a sensation like flashes of lightning in his left eye, more especially towards the left side, and the sight of that eye began to diminish. This impairment of sight has increased since that time.

On examining him, I found the grasp of the left hand to be considerably less than that of the right; but, though the force with which he could use that hand and arm was diminished, he retained every kind of movement—could open and shut his hand freely, raise his arm over his head, dress and feed himself without the least difficulty, and, in fact, there was none of that stiffness and awkwardness of movement which are seen in most cases of a slight degree of ordinary hemiplegia. In the same way, he did not walk at all lame or drag the left leg, but this leg became much more easily tired than the right; and when his power of resistance to forcible flexion and extension of the different joints was tested, it was found to be markedly less in the left leg than in the right. There was no facial paralysis, and he protruded his tongue straight. General sensation was very much dulled on the left side. In the face and tongue it was very much diminished, but not absolutely gone. In the arm he could scarcely feel the hardest pinch or prick at any part, and there was a similar obtuseness in the skin of the left side of the chest and abdomen. There was scarcely any sensation at the upper part of the thigh, but over the lower part of the leg and the foot there was only very slight diminution in the sensibility. He was unable to smell at all with the left nostril, the right being normal. He was unable to read a single word with the left eye, but with the right he could read a newspaper easily. He could only hear a watch when placed in actual contact with the left ear, but with the right he could hear it at a distance of a foot or eighteen inches. Taste was quite abolished at the front of the tongue on the left side; and, though not quite abolished at the back, it was very much less acute on the left than on the right side.

Metallic applications were tried in this case, but without any sensible result. The patient remained in hospital for several weeks, but without material change in his symptoms.

The anæsthesia which occurs in chronic alcoholism has been specially described by M. Magnan in his book *De l'Alcoolisme*. M. Magnan says that, in such cases, "whether after a sudden apoplectic attack with loss of consciousness, or little by little without other morbid phenomena than headache, dizziness, numbness, or formication on one side, the patients complain of muscular weakness, they drag the leg, let things slip from the hand, and sometimes even the speech is affected, or there may be slight facial paralysis. The paralysed side is anæsthetic—not only the skin, but the mucous membranes and the deep structures. When the anæsthesia is complete, the different varieties of sensation are abolished; neither touch, tickling, pricking, heat and cold, nor the constant or induced currents are felt. The muscular sense is diminished, and sometimes entirely abolished. The anæsthetic members are habitually colder than the healthy ones. Sometimes the difference of temperature between the two hands may attain to between two and three degrees centigrade. The special senses offer modifications no less remarkable. There may be merely a slight enfeebling, or there may be complete abolition of function. There is amblyopia, and also a loss of perception of colour. The hearing is dull; the sense of smell is diminished, and sometimes entirely abolished. The taste is diminished or lost on the anæsthetic side. In such cases, the motor symptoms sometimes rapidly pass off, whilst the sensory remain; at other times, the two sets of symptoms pass off *pari passu*; whilst in other cases, again, the motor and sensory symptoms grow progressively worse."

I will add a *résumé* of one of the cases reported by M. Magnan, that of a man who had been a drinker from the age of nineteen years. He had drunk much absinthe, and had had one epileptic attack. For two years he had suffered from paresis of the right side, with trembling of the limbs, which was more marked in the right than the left side. He was admitted into the *hospice* of St. Anne with alcoholic delirium. On admission, he was suffering from muscular weakness and anæsthesia of the right side. When the arms were extended, the right arm became much sooner tired than the left, and the trembling became much more marked; when the right leg was raised from the bed, it became much sooner fatigued than the left. The grasp of the hand was notably less on the right side than on the left, and the patient had difficulty in standing on the right leg, but could spring with ease on the left foot. Pin-pricks which were felt less than in the normal condition on the

left side were not felt at all on the right, there being complete anæsthesia of that side. There was amblyopia of the right eye. Odours were not perceived in the right nostril; hearing was feeble in the right ear; and the sense of taste was very much dulled on the right side of the tongue. The hemianæsthesia persisted for ten days without change, but after that it began to improve; and, five weeks after admission, the sight appeared equally good on the two sides, the hearing was much improved, but remained a little obtuse in the right ear, taste was improved, and he could smell equally well with the two nostrils. The general sensibility, though improved, continued to be dull on the right side. The trembling ceased on both sides. The treatment consisted in the administration of iodide of potassium in doses of fifteen grains *per diem*, with a bitter tonic.

M. Magnan gives details of several other cases of the same order which have occurred in his practice, in some of which there was a more or less complete recovery, and in others a progressive increase in the severity of the symptoms. In one case, there was a return of the hemianæsthesia with each attack of alcoholism; in another, sensation, general and special, returned, with the exception of the sense of smell.

In a case of alcoholism which came under my own notice at the Hôtel-Dieu at Paris—that of a man of middle age, under the care of Professor Germain Sée—there was complete hemianæsthesia, both general and special. In this case, the metallic applications were tried, and sensation was completely restored, as in the case of the hysterical patients. I regret that I cannot give the observation in detail, as I unfortunately took no notes myself, and I have been unable to obtain any from the *interne* of the ward.

I will now pass on to the hemianæsthesia, general and special, which exists in rare cases of organic disease of the brain. Attention was first called to these cases by Ludwig Türck\* in the year 1859, when he described four cases of hemiplegia with hemianæsthesia in which necropsies were made; but in two only of these cases was there special as well as general anæsthesia. One of these patients was a young woman aged 22, who died six months after an apoplectic attack, which had deprived her of power and of sensation, general and special, on the right side. The power returned almost entirely, but the anæsthesia remained. A patch of softening was found lying outside the optic thalamus, and involving the outer two-thirds of the foot of the corona radiata. The optic thalamus itself was not injured. The other case was that of an old woman, who had been the subject of right hemiplegia for several years, accompanied by complete hemianæsthesia special and general. At the necropsy, an old apoplectic cicatrix was found lying along the outer side of the left optic thalamus, affecting a considerable extent of the posterior portion of the expansion of the corona radiata, part of the internal capsule, and perhaps also a portion of the lenticular nucleus.

The only other cases of the same nature of which I have been able to find a record are two cases which occurred in the practice of M. Charcot at the Salpêtrière, and which were reported by M. Pitres (*Progrès Médical*, 1876, p. 522). The first of these was a woman fifty-eight years old, who had been hemiplegic for four years, and in whom both general and special sensation were lost. At the necropsy, a patch of softening was found in the posterior half of the optic thalamus, which extended outwards so as to destroy the caudate nucleus involving the back part of the internal capsule. The second case was that of a woman who had been hemiplegic for twenty years, the leg being more affected than the arm. Sensibility to ordinary touch was very little affected, but the power of appreciation of pain was almost completely abolished. Sight was fairly good in both eyes, but the field of vision on the affected side was concentrically contracted in a very marked degree. The senses of hearing, smell, and taste were very much dulled on the hemiplegic side.

Two cases in which hemiplegia was accompanied by loss of sight in the eye of the affected side have been reported by Dr. Bernhardt (*Berliner Klinische Wochenschrift*, September 6th, 1875); but in these cases no note has been made of the condition of the other special senses, so that they are useless for my present purpose.

I met with a case of this rare form of hemiplegia, in one of the hospitals in Paris, which presented all the characters above described, with the exception that the loss of sight was on the opposite side to that which was paralysed. I subjoin the notes which I took of the case.

CASE.—L. M. F., male, aged 32, employed on a railway, was admitted into the Hôpital Temporaire, under the care of M. Lépine, on May 30th, 1877.

\* Ueber die Beziehung gewissen Krankheitsherde des grossen Gehirnes zur Anæsthesie." Aus dem xxvi Band, S. 191, des Jahrganges 1859, des Sitzungsberichte der mathem.-naturw. Classe der kais. Akademie der Wissenschaften.

*History.*—His previous health seems to have been fairly good. He had an attack of acute articular rheumatism three or four years ago. He never worked in lead. He denied syphilis. He had never had sore-throat. About a year ago, he had an eruption on the chest, for which he was ordered baths, but no medicine; and it disappeared after a fortnight's treatment. He was in good health until six weeks or two months before admission, when he began to suffer from very severe frontal headache, which was worse at night, and was sufficiently severe to keep him awake. At the beginning of May, he had an attack one evening, with loss of consciousness. On coming to himself next morning, he found that he was paralysed on the left side. He could not stand for four days, and it was still longer before he could hold anything in his hand. There was some difficulty in speaking; he did not forget his words, but could not pronounce them properly. He had gradually grown stronger; and, on admission, could walk about the ward, dragging the left leg a little. The grasp of the left hand was considerably less than that of the right, and he had difficulty in raising the arm over his head. When he was looking at an object in front of him, there was from time to time a little irregular movement in the eyes—a slight involuntary roll. If, however, either eye were shut, the other eye became the subject of very marked nystagmus—mainly horizontal, and coarse in quality. If he were looking with both eyes in such a way as to put the muscles on the strain, the nystagmus again came on, but to a less extent. The pupils were equal, and acted well to light. There was distinctly deficient action on the left side of the face; the left corner of the mouth was less retracted than the right when he showed his teeth; and he had been unable to whistle since his attack, which he could do easily before. There was almost absolute loss of general sensation over the whole of the left side of the body; he could only just feel the hardest pinch in the head, face, arm, trunk, or leg; he did not feel a touch on the left conjunctiva or left side of the tongue. The special senses, moreover, were affected; he was unable to smell with the left nostril; he was barely able to hear my watch placed in close apposition to the left ear, though he heard it at a considerable distance with the right. Taste was nearly or quite absent on the left side of the tongue. When his sight was examined, however, it was the right eye which was deficient, and he had great difficulty in reading with that eye what he read with ease with his left. This partial blindness of that eye, he believed, had come on since his illness, as he had good sight before. The field of vision, tested roughly with the fingers, appeared normal.

I may mention that Professor Charcot has found that there is a frequent connection between posthemiplegic chorea and this particular form of hemianæsthesia, and his observations have been confirmed by other observers so far as the sense of sight is concerned. Thus, in the two cases reported by Bernhardt (*loc. cit.*), loss of sight in the eye of the hemiplegic side was associated with choreic movements in the limbs of that side. In one of Professor Charcot's cases at the Salpêtrière that I had the opportunity of seeing, an elderly woman, who had suffered from hemiplegia for several years following an apoplectic stroke, had general and special anæsthesia, associated with choreic movements. Metallic applications were tried, and were followed by very marked improvement in the sensibility. M. Charcot has mentioned another case of the same kind which occurred in his practice (*Progress Medical*, Jan. 20th and 27th, 1877).

To sum up, then, we find that an affection of sensation, general and special, of every order, may be met with in a considerable variety of conditions besides hysteria, and that which is due to hysteria differs in no way from that which results from other causes, gross organic lesions not excepted. We find as a rule the whole realm of sensation involved, but in the hysteria, as well as in the other conditions, we may find one special sense, or certain districts of skin unaffected; thus, in the case of lead-poisoning, the sensation of the foot was nearly normal, whilst everywhere else the patient was anæsthetic.

The affection of sight, again, is in all quite different from that seen in most cases of organic hemiplegia where the optic centres are involved, for in these we find hemiopia—*i. e.*, blindness of that half of the field of vision in each eye which corresponds with the paralysed side. In the cases of which I am treating, however, we find affection of the eye on the paralysed side only, the other eye being intact, and the affection consists of concentric diminution of the field of vision in all directions, which may, in some cases, amount to complete blindness. The exceptional case I have myself reported of organic hemianæsthesia, in which it was the opposite eye that was nearly blind, I leave, as this was an anomaly for which I am unable to account.

Another feature which the hysterical cases have in common with those due to other causes, is the transitory nature of the symptoms. In several of Dr. Magnan's alcoholic patients, the sensibility returned within a few days or weeks after they came under treatment;

and, in at least two cases in which the hemianæsthesia appeared to be due to an organic lesion, sensation returned after the metallic applications.

I shall not attempt in the present paper to enter upon the difficult question as to the mechanism of this singular condition, whether in hysteria or in other maladies; still less shall I enter into the much vexed question as to the explanation of the efficacy in certain cases of metallic applications. My object has been to show that hysteria is by no means the only condition in which special and general hemianæsthesia is met with; that it is found not only in certain diseases—such as lead or alcoholic poisoning—in which we may suppose it belongs to the so-called functional symptoms; but also that it may be due to a distinct and localised organic lesion which can be accurately defined by necropsy. Instead of allowing ourselves to be dominated by blind scepticism when our attention is called to hitherto unnoted phenomena, let us bear in mind how very imperfect is our knowledge of the functions of the brain, and endeavour to apply our new knowledge to the elucidation of its problems.

## LIFE-ASSURANCE AND RESIDENCE IN HOT CLIMATES.

By C. R. FRANCIS, M.B. Lond.,  
Surgeon-General in Her Majesty's Indian Army (Retired).

WITH reference to the extent to which residence in hot climates reduces, if at all, the eligibility of European life for assurance, I venture to offer the following remarks. Having been Staff Assistant-Surgeon to the dépôt at Warley at a time when recruits for the army in India were examined and admitted in large numbers, and having served for many years with European as well as native troops in various parts of that country, besides holding appointments in which the examination of lives for assurance formed part of the ordinary duties, I may perhaps be allowed to claim a fair share of experience on the subject. My only object being to invite attention, for the benefit of both assurance companies and of medical officers attached to them, to a subject which, so far as I am aware, is not discussed in any special English treatise, I hope I may be pardoned for thus noticing it; which I do in the hope that, if necessary, some abler pen will pursue it.

An impression—in a great measure erroneous—prevails with many assurance companies and medical practitioners that tropical residence is opposed to longevity. For the investigation of tropical lives—so to designate them—no general rule can, of course, be laid down. Each life must be dealt with separately on its own merits. But, unless the medical officer who examines it has been specially educated for the purpose, or has had special experience, his position, always responsible, as “one of the chief guardians of social morality and civilisation,”\* becomes, in such cases, exceptionally so, and in some very embarrassing. The primary object of a life-assurance company is, naturally, to do business. At the same time, its desire is to obtain as many young and healthy lives as possible. Given ancestral longevity and freedom from evil hereditary influences, individual youth, health, and regular habits, with an occupation free from danger—such a life is obviously very desirable. This amount of unmixed good in a single individual is, however, rare. One or more disturbing elements frequently exist, and are provided for; but I am inclined to think, from a perusal of the examination-papers in use with various assurance offices, that, in the case of tropical residence as one of these elements, the inquiries might be so framed as to enable the medical examiner to arrive at the true value of the examinee's life with greater exactness than the present system in those offices admits. Some offices look so seriously upon tropical or Indian residence, that they occasionally double the premium; in others, lives in India are assured at home-rates. *In medio tutissimus ibis* is an axiom that may well be applied here. That the risk of life in India is, *acteris paribus*, greater than it is in Europe must be admitted, because cholera and insolation—diseases which, in their season, destroy or damage life to a vast extent—cannot be eliminated from the calculation. Since the days when an undertaker in Calcutta offered 20,000 rupees for the business and goodwill of a brother undertaker for a single month (September) up to the present time, the value of European life in India has steadily increased. Improved systems of drainage, a better water-supply, facilities for rapid escape from noxious influences and for recruiting injured health, added to more rational modes of treatment and recognition of hygienic laws, have combined to reduce the mortality in later years from 40 per 1,000 during the three years ending 1813 to

\* *The Medical Adviser in Life Assurance.* By E. H. Sieveking.

less than half that number in the decade ending 1870.† Still, the mortality generally is higher than in the United Kingdom. We learn from the *Army Medical Report for 1875* that, during the ten years ending 1874, the death-rate from all diseases amongst non-commissioned officers and men was—in Bengal, Madras, and Bombay—double that in Great Britain and Ireland. It is true, that these latter classes suffer more than officers. Nevertheless, the broad fact of a general higher death rate, and of a certain amount, therefore, of Indian risk, remains. What that amount may be, it is not very easy to determine. The Directors of the Standard Life-Assurance Company—a company that probably assures more tropical lives than any other in the United Kingdom—whilst admitting that their rates will bear a certain reduction at the younger ages, believe that, at those which are older, they must, in the new policies, be increased. From a statistical point of view, these calculations may be correct enough; but, notwithstanding, it by no means follows that individuals may not live as long in India, or after returning home, as if they had never left England.

This brings me to the object of the present communication—viz., that each tropical life must be dealt with on its own merits; and that the rates for such a life should, in each case, be special. Much must depend upon circumstances. The military and the civil life differ broadly from each other and in themselves. The officer with his regiment, for example, may (barring the element of danger from his vocation) lead a healthier life, if he please, than many civilians, or officers in civil employ. The station where his regiment is quartered is changed in the annual relief once in two or three years; and the march with it (a good deal abridged in the present day, owing to railways), extending often over several weeks, is usually most invigorating. Then he may annually take sixty days' privilege leave to the hills; and his occupation, generally, secures for him a fair amount of air and exercise. The civilian, on the other hand, and the merchant, pass several hours daily in a more or less unwholesome atmosphere—the former in *cuteherry* (judicial court), the latter in his office. The planter, again, with his early rising, long rides over his estates, and regular habits, often attains a good old age in India, enjoying far better health (and showing it in his face and *physique*) than very many in England.

The part of India, moreover, makes a vast difference. One man may pass the greater part of his service in the hills—in an English climate, in fact. Another may have sojourned under malarious influences in what are known as the penal settlements in the plains. The liver and spleen of the former may be as free from all trace of disease as when the proprietor left England, whilst those of the latter may be seriously injured. Then the aggregate length of residence is not the same as consecutive length. Facilities of communication, and less stringent leave-rules throughout the services, make it easy for all to come home more frequently, and thus renew their strength. In former days, when men identified themselves more with the country, and remained there thirty or for years continuously, doubtless, for them, a return to England, at an advanced period of life moreover, might be hazardous. But this is now all changed. Men go to India to fill their coffers, and return as rapidly as possible. Obviously, in such cases, the climate *per se* would tell less than upon the long resident. Something must, of course, be said for acclimatization. Many men become injured to the climate. Dr. F. Moat reminds us, in the pamphlet above referred to, that Sir James Annesley, in his *Sketches of the most Prevalent Diseases of India*, divided the 115 European gentlemen who died in the Madras Presidency in the years 1813, 1814, and 1815, out of 1,366, into three classes: the first class who had resided twelve years and under in the Peninsula, with a death rate of 47 per cent. *per annum*; the second, residents above twelve and not exceeding eighteen years, whose mortality was something less than 3½ per cent.; and the third class, whose residence amounted to eighteen years and over, who lost only 2½ per cent. of their number. For the thoroughly acclimatized in India, a return to Europe would naturally be somewhat hazardous. The power of adaptation to climate and other circumstances inherent in the human constitution is marvellous; but this power must naturally diminish with advancing years. In examining a tropical life, habits should be carefully inquired into. Those of a prejudicial tendency are too easily acquired in the East. Hence the advisability of referring a tropical life to two friends—one who knew the assured before he went abroad, and who had renewed his acquaintance with him since his return; another who knew him well in India. The fact of a man having been in his profession would be in his favour, although the question must not be accepted too readily as adverse. A singular apparent inconsistency is sometimes seen. A man comes home sick,

Soon, the *res angusta domi* of England brings on an attack of impecuniosity; and he applies to an assurance office for a loan, ready to assure his life to cover it. The inconsistency is, however, more apparent than real. Men are very properly often sent home for ailments that would become aggravated by continued tropical residence, whereas they shake them off rapidly in England, and are frequently well before even leaving the vessel. Such lives may, in truth, be perfectly sound. Some lives are improved by residence in India—the strumous, for example. I am acquainted with a retired (Native) Infantry Colonel, now in his fifty-fifth year, whose mother died early in life, after giving birth to this, her only child. He was a sickly little fellow. Struma displayed itself in a marked and exaggerated degree. His neck was scarred from glandular abscesses, and one of his elbow-joints became ankylosed after chronic ulceration; whilst his voice, from a similar condition in the larynx, lost the masculine, and acquired a feminine, tone. Now he passed for the Indian military service I am not prepared to say. He did pass into it, however; and he rapidly began to improve in health. The climate suited him, and his constitution soon underwent a wonderful change for the better. He came home from time to time on furlough; and now, having served the State well as a regimental officer in India for more than thirty years, has retired in the full enjoyment of life, and likely, humbly speaking, to live for many years. His male ancestors were healthy and long-lived. Had he remained in England, phthisis would probably have carried him off before he had completed his fifth lustrum. It must be remembered that in a hot climate the lungs are not, as in a cold one, actively employed. Their ordinary office of eliminating carbon from the system is undertaken, for the most part in India, by the liver, which is, therefore, more likely to become deranged, or even diseased. I believe that the greater tendency to fatty deposit in tropical climates arises from the decreased activity of the lungs and the not always corresponding activity of the liver. It is well for the individual if obesity be the only result. Too frequently, where habits of life are favourable, fatty degeneration of tissue follows. Some years ago, I pointed out, from actual experiment, that, where Europeans had resided for a few years in the plains of India, there was apparently a positive diminution of weight in the lungs. Dr. Parkes, when alluding to this in his *Practical Hygiene*, mentioned that he had held the same opinion, though he had not enjoyed sufficiently frequent opportunities for testing it. This fact (comparative quiescence of the lungs in India), whilst it points to the expediency of locating European troops as much as possible in the hills, shows also that, after long residence in India, the lungs are less likely than other organs to be the seat of disease, whatever the proximity of ancestors, or nearer relatives, to phthisis. This leads me to speak of what kind of life is suited for India, or likely to do well there; in what way different lives are liable to be affected; and what derangements or diseases we may expect to find in tropical lives generally.

But, before going further, I should like to say a word or two on the examination of a "life". An intending assured is very different from a recruit for the army. The latter not being always full grown, allowance must be made for that, and, in some cases (it may be), for previous starvation, and consequently for future filling in. The difference between the raw recruit of twenty and the smart soldier two or three years later on is often very striking. The assured, on the other hand, is usually developed. Under a "short service" system, where, moreover, a proportion of the troops may be told off for garrison-work, a recruit may get through his allotted period of active servitude without difficulty, even though he may break down and die later in life. But the assured must live as long as he can. Every allowance should be made for the circumstances of the moment. A nervous examinee may wish to fortify himself beforehand. Alcohol will at first diminish, but afterwards accelerate, the pulse. A cup of coffee, taken at a neighbouring luncheon-bar, will quicken it in a marked degree. A meal of animal food will raise the pulse from five to ten beats per minute. Prolonged fasting, on the other hand, will reduce it by from twelve to fourteen beats per minute. Constitutional nervousness and various other points must be considered. Has the examinee walked rapidly to the place of rendezvous? Or has he come quietly in a conveyance? With reference to possible abnormal distribution, etc., the pulse should be felt in both wrists, alternately and together, whilst the assured stands and lies down. An interval, more or less long, according to circumstances, should be allowed to elapse between the assured's arrival and his examination. Doubtless, the respiration in all cases requires special attention; but, for reasons just stated, disease need not be expected there, notwithstanding the existence of phthisis in the family. Stress is sometimes laid upon the extent to which the apices fill: but general breathing capacity is required; and the direction in which this exists is not always the same,

\* In Dr. F. Moat's *England to India*, . . . from 1801 to 18 . . . inclusive. By F. J. Moat, M.D., F.R.C.S., 1875.

The relation of height to size and weight will, of course, be carefully considered. With regard to the lives that should go to India, it is understood that those in the services are picked lives; though, even with these, some points are omitted in the medical examinations which are deserving of inquiry. At present, if an individual have been vaccinated or had the small-pox; if he show no tendency to insanity, or epilepsy, or hernia, etc., he is, *ceteris paribus*, considered eligible, and passed; and yet he may not be so fit as appearances indicate. The dyspeptic, for example, especially if he be liable to low spirits, should not make India the land of his adoption. The swarthy and the fair\* complexioned should alike avoid it; the former being likely to suffer from "liver", the latter from "sun". Those who have "weak bowels" should not risk it. The practice of sending the consumptive (under all circumstances) to India is, happily, diminishing, as it is becoming generally understood that certain parts of that country—the low damp climate of Bengal, for instance—are quite inimical to such cases. In the higher and drier stations, improvement may be expected. The hill-station of Ootacamund, in the Madras Presidency, is particularly suitable. Notwithstanding the risks from climate that have been here referred to, the *res angusta domi* is too often all-powerful in determining the future career of a youth. Interest, too, may influence, and the prospect of prizes not attainable at home. Under any circumstances, the man who has decided upon India should, whenever possible, consult a physician experienced in tropical disorders as to his proclivities and the best mode of obviating them.

In examining a tropical "life", attention would naturally be drawn to the complexion. This may be natural, or it may be the result of permanent destruction of the secreting portions of the liver. Even in the latter case, there is no cause for special consideration, as, if the assuree have left India for good, there may yet be quite liver enough for health. The general bearing is very important. Indications of disordered nervous system should be carefully sought for. Shattered nerves are frequently the result of a prolonged residence in India. The liver and spleen will obviously require especially careful examination. However disagreeable the duty, if there be the least suspicion, be the intending assuree married or single, the medical officer should look for signs of blood-poisoning from syphilis. The dissemination of this poison, and its effects, in India are much greater than is commonly supposed. The kidneys will be seldom found to be the seat of disease.

With regard to the question—Has the assuree, one of a long-lived family, who has lived in India for thirty years (including half-a-dozen spent in furloughs of two years at a time), as fair a chance of living to a good old age as other members of the family who have never left England?—the answer must obviously depend upon circumstances. Here is an example. A. B., who was recently examined at an assurance office, did not go to India till he was twenty-three. He had led a careful life in England, and his habits were regular. He had not (when he presented himself for assurance, at fifty-seven) suffered at any time from serious illness. He had risen rapidly in his profession, and, at fifty-five, retired from the Indian service in good health. His ancestors, on the male side especially, were remarkable for longevity, their several ages at death varying from eighty to ninety-five. His father, naturally a hale active little man, died at sixty, in India, having imprudently played at cricket, of which he was particularly fond, in a damp misty month (February), at one of the dampest stations in Bengal. The induced catarrh became a fatal bronchitis. Beyond occasional attacks of dyspepsia, he had never, during a service of nearly forty years, been ill; and, humanly speaking, had he not, for the sake of promotion, returned to India at so advanced a period of life, he might have been living now. Considerable stress was, however, laid upon the fact of the death at a comparatively early age by the medical officer of the company, whilst no questions were asked as to the longevity of A. B.'s family. A. B.'s mother's family were also long-lived; but his mother had died of cancer of the breast at fifty-five, and a sister of phthisis at forty-four, years of age. These facts, taken separately and without inquiry, would obviously be very important. But investigation would have elicited that the former, of excellent *physique*, had never complained of even a headache till she was fifty. Then, with a change in the uterine functions, a scirrhus tumour appeared in the right breast. It was completely removed by an eminent London surgeon, and she continued for four years to enjoy her usual good health; when she became a widow, and then, the tumour having reappeared, and life no longer having any charms for her, she abandoned herself to her fate. The tumour became an open sore, and death soon followed. The sister, who died of phthisis, had gone with her

parents to India when eighteen years of age, and married and became a mother shortly afterwards. Frequent pregnancies and continued lactation undermined her strength (European mothers, as a rule, are less able to suckle their off-spring in India than they would be in England); and, at twenty-eight, tubercles were detected in the left lung. For sixteen years she battled with the disease; and, from time to time, regained very much of her former good health. But her condition was not treated with the serious attention it deserved; and, at forty-four, the poor sufferer finally succumbed. Four of A. B.'s brothers and sisters had died in infancy. Much, too, was made of this point. But what were the facts about which no questions were asked? Three of the children had died half a century ago in India from the effects of teething (a period more trying to European children in a tropical country than in a cold one), when the diseases of childhood, moreover, were less understood, and when, owing to difficulties of transport, change of air—so important a factor in aiding recovery—could not readily be obtained. The fourth infant died in England from unchecked hæmorrhage after leech-bites—a melancholy instance of neglect. When A. B. left India, he was advised not to do so, as he had evidently, it was urged, twenty years more work in him even in that country! The result of A. B.'s medical examination was, that three years were added to his life in the policy. Too great importance was attached: *a.* To the idea of blood-poisoning (cancer) in the mother, and to its hereditary nature; but, as Dr. Sieveking observes, "the female organs of reproduction are specially liable to the disease, and...the female sex has an infinitely greater proclivity to cancer than the male sex; and the taint, if any, would scarcely affect the assuree; *b.* To the death of the sister from phthisis; for although, as the same author has observed, "where both (cancer and tubercle) occur in the same family, any member of it must be regarded as bearing a double risk", the circumstances of the case were such as would not affect A. B. himself, whose lungs had for so many years been under tropical influences; *c.* To the deaths of so many members of the family, as to the circumstances attending which, however, no inquiries were made; *d.* To the death of A. B.'s father from a chest-affection. And yet, whilst stress was laid upon these points, leading to an increased rate of premium, no inquiries were made about the longevity of A. B.'s ancestors, male or female, and no careful investigation was made of those organs and parts of the constitution which would be liable to derangement after so long a residence in India. The satisfactory result of inquiries in these directions should quite have neutralised any unfavourable opinion formed upon a consideration of the four adverse (?) facts above referred to. A. B., who has a sister five years younger than himself—also a tropical life, enjoying excellent health—might, with her, be considered a "selected life".

## COMPLETE INVERSION OF THE UTERUS: REDUCTION ON THE FIFTEENTH DAY.

By ALEXANDER FORD, L.R.C.P.Ed., Harrogate.

INVERSION of the uterus is so rare an accident that the following case may not be without interest.

On February 20th, Mrs. B., aged 22, primipara, was delivered of a healthy child. During the later months of pregnancy, she suffered from a fixed pain on the left side; but her general health was good. Labour was normal as regards the first and second stages. After the expulsion of the child, I waited about ten minutes and made traction on the cord, maintaining pressure on the uterus with my left hand. The cord snapped off. I then introduced my hand into the uterus and grasped the placenta, which was partially adherent. I removed all but a small piece. Presently my patient lost a large quantity of blood. She said she "could not see", and felt as though she should "sink through the bed". Her countenance became deadly pale, and her pulse so weak and fluttering that I could not count it. I administered stimulants freely and she rallied. I left her at 11 A.M. I saw her again in the evening and found her very weak.

On the following day, the patient complained of having severe after-pains and cramps down the thighs. The bladder had not acted. I drew off her urine, introducing my finger into the vagina to serve as a guide to the orifice of the urethra. There was no change when I saw her in the evening. I passed the catheter, and administered an opiate.

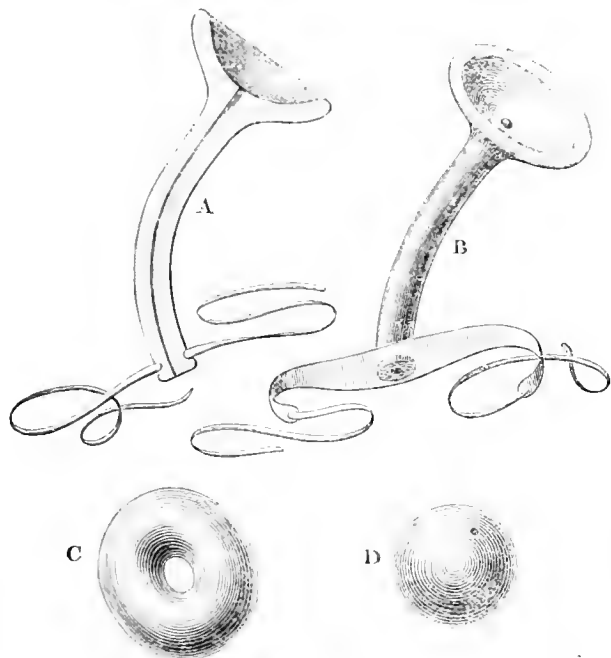

On February 22nd, my patient's condition had altered in that the cramps had subsided; the bladder had not acted. On introducing my finger into the vagina, I came upon a globular body filling up that canal, and this body was the inverted uterus. I made an attempt—a poor one, I must admit—to reinvert the fundus, and failed.

On February 23rd, Dr. Myrtle saw the patient with me, and rightly

\* The fair scrofulous, for whom the warm and dry parts of India are usually well adapted, are not, of course, included in this category.

judged that reduction would be difficult. Acting on his advice, I consulted Dr. James Braithwaite of Leeds.

On February 25th, the patient was seen by Dr. Braithwaite. His attempts at reduction were unsuccessful. He was, however, of opinion that the end might be attained by tiring out the os uteri, and suggested the exertion of steady pressure on the fundus. The apparatus used for this purpose is depicted in the accompanying diagram. C represents an India-rubber pad, which was fitted to the cup-shaped depression at the extremity of the vulcanite pessary B, and maintained in position by a string which was knotted inside the India-rubber ball D, and had its other end passed through the annular pad C, and through the stem of the pessary A. The apparatus was kept *in situ* by two straps, attached behind and in front to a belt passed round the abdomen. The diameter of the cup-shaped end of the pessary was two inches.

I began this plan of treatment on February 26th, and for the first three days I removed the instrument every morning and renewed my attempts at reduction daily. It then occurred to me to keep the apparatus in constantly, and merely undo the straps in order to draw off the urine and syringe out the vagina. I was led to believe this the better mode of procedure, because the daily removal and reintroduction of the instrument caused the patient much pain, and because the attempts at reduction excited strong expulsive efforts.

March 1st. The pessary was not withdrawn. I contented myself with emptying the bladder and washing out the vagina. I kept up steady pressure on the fundus until the evening of March 6th.

On March 6th, Dr. Braithwaite again saw Mrs. B., and reinverted the uterus while the patient was under the influence of chloroform.

I believe that in Mrs. B.'s case the inversion was not complete until the third day after delivery. The extraction of the placenta caused, I have no doubt, a depression of the fundus, and this depression terminated in the extraordinary accident which is the subject of these remarks. The process of inversion was going on during the day following her confinement; and the cramps were due to the circumstance that four layers of uterine wall occupied the vagina. It was not yet complete; for my finger did not come upon the fundus when emptying the bladder. It was not until about 2 A.M. of February 22nd, that the patient felt a sense of relief from the cessation of the cramps, and on the morning of that day my finger encountered a globular body occupying the vaginal canal. The removal of the placenta was unattended with any difficulty; it did not require as much manipulation as some others which I have had occasion to remove.

Were the symptoms which immediately followed the removal of the after-birth such as to have led me to infer what was the real nature of the case? If so, I did not interpret them aright. They were alarming enough, but not conclusive. Very similar symptoms occur without there being inversion. On January 18th, I attended Mrs. M., aged

34, primipara. Beyond a protracted first stage, there was nothing in the least abnormal in her labour. There was not a single accidental complication, and yet her condition bore a striking resemblance to that of Mrs. B.

## CLINICAL MEMORANDA.

### DIPHTHERIA: CROUP: TRACHEOTOMY.

IN a short communication on the above subject by Dr. Bowles in the last number of the JOURNAL, there occurs the following statement. "Lastly, Dr. George Johnson in a contemporary so far changed his front as to state that bad drains (*strains* is evidently a misprint for *drains*) as well as diphtheria are responsible for false membranes."\* And Dr. Bowles goes on to predict the triumphant results of this assumed "change of front".

I believe that the paper to which Dr. Bowles refers is one published in the *Lancet* of February 16th, in which I state, as the result of my own investigations, that, "in the absence of direct contagion, the occurrence of membranous pharyngitis or laryngitis affords conclusive evidence of infection by sewage-poison conveyed through either air or water". By this, of course I meant to say that the membranous exudation which characterises diphtheria, when not the result of direct contagion from a previous sufferer, is caused by a drain-poison. That so plain a statement should have been misunderstood by so intelligent a physician as Dr. Bowles, makes one almost despair of the possibility of escaping misconstruction. Does he maintain that a false membrane which has resulted from infection by a drain-poison cannot be diphtheria? To state that "bad drains as well as diphtheria are responsible for false membranes" would seem to me to be as absurd and unmeaning as to affirm that bad drains as well as typhoid fever are "responsible" for ulceration and sloughing of Peyer's patches. In the paper to which reference is made, I simply maintain the doctrine which is very generally accepted, that the diphtheritic poison, like the typhoid poison, often escapes from a defective drain; and I further insist upon the practical importance of tracing the infection to its source, and not erroneously attributing a membranous exudation to exposure to cold or heat or other non-specific agencies.

GEORGE JOHNSON, M.D., F.R.S.

## SURGICAL MEMORANDA.

### ROTATION OF THE SPINE.

MR. CHRISTOPHER HEATH, in a clinical lecture delivered at the University College Hospital on the subject of lateral curvature of the spine, which is reported in the JOURNAL of May 25th, supported the theory advanced by Dr. Sayre, that the rotation of the vertebrae which is present in this deformity arises from the unbalanced action of the serratus magnus muscle. Dr. Sayre's theory is as follows. The scapula becomes a fixed point by contraction of the rhomboidal muscles; the serratus magnus acting from this fixed point draws upon the ribs, and converts them into levers of the first class; the power being at the attachment of the serratus magnus, the fulcrum at the transverse process, and the weight at the body of the vertebra. The serratus magnus, by its contraction, acts on the long arm of the lever and rotates the vertebra. The fallacy of this theory is evident. The scapula becomes a fixed point by contraction of the rhomboid muscles; therefore the spinous processes from which these muscles take origin must also be fixed points; that is to say, the vertebra is at one and the same time a rotating body and a fixed point, which is absurd.

FREDERICK R. FISHER, F.R.C.S., Surgeon to the National Orthopaedic Hospital, etc.

### CASE OF EXTRACTION OF A BULLET FROM THE SHEATH OF A TENDON AFTER FIVE MONTHS' LODGMENT.

ON April 30th, I was consulted by a young woman with reference to a very prominent tumour on the back of her hand. It was perfectly painless; and her only reasons for seeking advice were the obvious disfigurement and a slight difficulty attending piano practice. Its situation was between the metacarpal bones of the middle and ring fingers, its centre being rather less than an inch from the metacarpophalangeal articulation. It was hard, inelastic, and slightly irregular

\* Dr. Bowles has sent us a note stating that the word "*strains*" should have been "*drains*"; and that the commencing word "*lastly*" should have been "*lately*".—ED.

in outline, and admitted of no movement except a very little on flexion of the ring finger. No tenderness on pressure was present. There was also a small scar on the latero-posterior aspect of the ring-finger, at about the junction of the upper and middle thirds of the first phalanx. This, the patient stated, was caused by a wound from a catapult received early in the preceding December, simultaneously with which the tumour became apparent. Such a history, combined with the physical characters, at once determined me to extract what was evidently a foreign body. After division of the skin and subcutaneous structures, the tumour was seen to be of a darkish colour, and to be within the sheath of the extensor tendon, on section of which a leaden bullet was found. This was five-eighths of an inch long, with a diameter of five-sixteenths of an inch, and was obliquely inclined to the surface of the hand. In four days, the wound was healed, no suppuration having taken place, and the patient can now use the hand as well as ever. Antiseptic precautions and treatment were not adopted.

The chief points of interest seem to me to be, first, that the bullet should have travelled so far up the sheath and remained there so long without setting up any inflammatory mischief. Indeed, we may fairly suppose that it might have remained there indefinitely without harm. And secondly, operative interference involving the sheath, and that not antiseptically conducted, was in the same respect equally happy in its results. I may, perhaps, mention that while the original wound was still bleeding, two surgeons, who separately saw it, failed to diagnose the nature of the tumour, one ordering poultices, and the other saying it was "congealed blood" and painting it for some days with iodine.

W. GEO. CRESWELL, L.R.C.S. Edin.

## REVIEWS AND NOTICES.

LECTURES ON DISEASES OF THE NERVOUS SYSTEM, delivered at Guy's Hospital. By SAMUEL WILKS, M.D., F.R.S. London: J. and A. Churchill. 1878.

DISEASES OF THE NERVOUS SYSTEM, THEIR PREVALENCE AND PATHOLOGY. By JULIUS ALTHAUS, M.D., M.R.C.P. London: Smith, Elder, and Co. 1877.

THESE two works on Diseases of the Nervous System, which we owe to Drs. WILKS and ALTHAUS, may be grouped together with more justification than is afforded by mere community of subject. They are, to some extent, complementary. Dr. Wilks gives us the experience of a long period of acute observation, careful thought, but not very wide reading. Dr. Althaus' work contains a brief but clear account of the work of the chief European labourers in the same field; and the author has added some interesting facts obtained by careful study of the Registrar-General's tables.

The lectures of Dr. Wilks are a reprint of those which were published some ten years ago by a contemporary, with additions, many of which have appeared from time to time in the *Guy's Hospital Reports*. The lectures apparently formed part of a course on systematic medicine. They constitute a survey of the whole field of nervous disease; and, although systematic in intention, are illustrated by the narration of a large number of cases. In generalities they are excellent, in details somewhat inadequate. The more important points, both of general principle and special disease, are singularly well discussed; such, for example, as the phenomena of aphasia, epilepsy, and hysteria. Every one who knows the careful philosophical thought and power of varied illustration from general literature which the author brings to bear upon every subject, will be prepared to find such points treated in a manner interesting and instructive, and he will not be disappointed. The absence of some of the elements which may by many readers be missed in the book is explained in the preface, in which the author admits the absence of "precise scientific material" of a "scientific method", and of proper references to the labourers whose works have been embodied in it.

The form of a lecture, we are told, does not admit reference to the sources of information from which the lecturer draws. This is true; but the transfer to the printed page of the conditions of the oral lecture is not altogether justifiable. At the same time, few of the readers of these lectures, who care more for what is said than whence it comes, will be inclined to regret omissions which increase the ease of perusal.

Throughout the work, the descriptions of disease and pathology are accurate and trustworthy, the account of symptoms is clear, and the remarks on treatment, as far as they go, are careful and wise. The work is divided into four sections, comprehending respectively diseases of the brain, of the spinal cord, functional and general diseases, and

diseases of the nerves. The first two are prefaced by an account of the anatomy and physiology of the centres. The best parts of the work are unquestionably the description of the diseases with which the author's daily work has made him thoroughly familiar, and has compelled him to constant and reflecting study. In order to convey an idea of the manner in which the subjects are treated, we cannot do better than quote the following passage from the account of the causes of hysteria (page 373).

"It sometimes surprises me that medical men declare their utter helplessness when standing by the bedside of an hysterical patient. They will confess that all means have been tried in vain, that there is no real disease to cure, that it is an imaginary or nervous disorder, where nothing can be done, when all the while it is their own presence in the case which constitutes the very root and foundation of the malady. Let us take the case of a girl who keeps to her bed with an ideal paralysis of the legs or some similar disorder. She is the interesting invalid, and receives, in consequence, the sympathies of inquiring friends, the consolation of the clergyman, and, above all, the daily visit of the medical practitioner, who prescribes appropriate physic. The medical man declares that he has tried every means and failed. Should he not see that the whole affair is a drama of the patient's own creation, and she the central figure of the piece? Is he not aware that to cure her he must break into the charmed circle, and to spoil the play he must get rid of some of the performers? And cannot he perceive that, even if he have no influence over others, he might withdraw himself? Here is a young lady who says, 'I will be ill, and have a doctor to attend me'. How can she accomplish this if the latter decline to obey her behests; or, if he accept the post, how can he, in the name of common sense, say he cannot break her of her fancy, while he is a party to it? If he see clearly the truth of what I have been saying, his duty is, as professional adviser to the family of the patient, to retire, and use his influence to prevent the calling in of another medical man."

There is no doubt of the correctness of the view that hysteria is, in many cases, a "medical disease" in a very literal sense. But we cannot concur in the practical rule of conduct which Dr. Wilks deduces. It is certainly true that many medical men conduce to the maintenance of hysteria, sometimes from fear of giving offence and losing a patient if they adopted a wiser course. But we believe that it never need be so, and that it is simply fear or ignorance of the proper mode of treatment of such cases that leads to the want of success. Such cases recover in hospitals, not in spite of the medical attention they get there, but usually in consequence of it; and medical attention, not always pharmaceutical, if judicious, should, and we believe does, help recovery in private also.

A careful and impartial summary of the facts known about chorea leads Dr. Wilks to the conclusion that it is impossible to accept the embolic, or any other theory which ignores the important facts that it is the result of fright and a disease of childhood. The latter is a far more prominent fact than the connection with heart-disease, although the latter is fully corroborated by his own experience. He has made many *post mortem* examinations in chorea, and has never failed to find evidence of endocarditis, whether a murmur had been present during life or no. The account of epilepsy and its symptoms and theories is very good. Dr. Wilks is one of the many who claim to have been the first to give bromide systematically in the disease. Next to bromide, he attaches the greatest value to zinc.

Other sections worthy of special commendation are those on the coarse organic diseases of the cord, and on cerebral tumour. The style of the work is lucid, and the method in which it is written excites an interest in the subjects discussed which is well sustained. It is probably the most "readable" work on the subject that we have.

Dr. Althaus's book is of a different scope. He professes to deal only with the prevalence and pathology of nervous diseases; but the latter word is probably used rather in its wide continental than narrow English sense, for as much clinical as pathological description is included in the several sections. The opening chapter and most original part of the work consists of an analysis of the Registrar-General's reports, in order to ascertain the actual prevalence and fatality of nervous diseases in this country. It is found that the rate of mortality from this cause is steady, and subject to a definite law to which there are not any, or only apparent, exceptions. The rate does not vary perceptibly from time to time, and amounts to about twelve per cent. of the entire mortality from all causes. Diseases of the nervous system occupy the fourth rank among the several classes of diseases as destructive of life, being only surpassed in mortality by the zymotic, tubercular, and respiratory diseases. They are not, as is often asserted, more frequent, but less frequent in large towns than in the country districts, and it is probable that their occurrence is largely influenced

by race. Sex has also a powerful influence on their production; for although in this country the number of females living exceeds that of males, the deaths of males from nervous affections preponderate constantly over those of females; the male death-rate being 12.94, and the female death-rate 11.62 per cent. Age has an influence still more powerful, for these maladies attain an immense maximum during the first year of life, owing to the great prevalence of infantile convulsions. They are much less frequent during youth and middle age, and attain "a second maximum" in old age, after seventy, owing to the prevalence of apoplexy and paralysis; but this second maximum amounts to only one-tenth of the first maximum attained during infant life.

The question next discussed is the system of classification of nervous diseases, and after describing one or two systems, the author states that which he employs. The general principles of this are pathological and good, but some of its details present considerable anomalies. For instance, locomotor ataxy and progressive muscular atrophy are placed almost at the opposite extremities of the list, the former being placed among diseases of the spinal cord, and the latter among vaso-motor diseases; although, in his description of the diseases, far her on in the book, it is clearly stated that it is a primary disease of the cord.

A carefully written summary of the physiology of the nerve-centres precedes the account of the symptoms and the pathology of the several diseases, which occupies the greater part of the volume; beginning with convulsions, and going on to apoplexy and its various causes, paralysis, encephalitis, epilepsy, hysteria and catalepsy, insanity, delirium tremens, tetanus, chorea, and structural diseases of the nerves, including tumour of the brain, and syphilitic affections of the nervous system.

Not only has Dr. Althaus tabulated the general facts of the mortality from nervous disease, but he has also worked out, and arranged in charts, the chief facts regarding the mortality from each disease. Many new and valuable facts are thus brought out. As an illustration, we may take the tables of the mortality from delirium tremens. A table is given showing the numbers of deaths in six periods of five years each, from 1838 to 1871. A diagram shows the influence of age. There is a blank until after fifteen years, at twenty the curve begins to rise, advances more at twenty-five, and reaches its maximum at thirty-five; a fall then takes place, which becomes rapid after fifty-five. This is compared with the tables of the Calcutta Hospitals.

The influence of sex is then examined, and, from a total of about 11,000 cases, is found to be as one woman to eight men in England and Wales, a proportion which contrasts unfavourably with the continent where, it is said, in several countries, not to occur in women. A curious chart gives the death-rate from this disease in the eleven registration districts of England and Wales. London heads the list, and if the death-rate there be taken as 100, it is found that the South-Eastern counties follow with 62, the North-Western with 57, the South-Midland with 55, the Northern with 54, Yorkshire with 42, the Eastern division with 41, the West-Midland with 40, the South-Western with 39, the North-Midland with 36, and last comes Wales with 27. It is a curious fact that, although the mortality in London from delirium tremens is so high, that from nervous diseases in general is low.

This example will show the valuable and instructive character of the conclusions Dr. Althaus has obtained by statistical investigation, and these constitute an extremely valuable part of the work. The several diseases are, however, very accurately described, and the account of their pathology is, in the main, a fair representation of the knowledge of the present day.

## NOTES ON BOOKS.

*Mason on Bare-Lip and Cleft Palate.* London: J. and A. Churchill. Mr. Mason has here collected reports previously published, in which he has stated his considerable experience in his own private and hospital practice and as an assistant of Sir W. Fergusson. He is, of course, in favour of early operation for bare-lip. In acquired cleft palate, he approves rather of cauterisation or of the use of obturators than of excision. He prefers to operate for congenital cleft palate at about six years of age, and recommends staphylorhaphy as the later rather than the earlier stage of operation. The whole of the operative procedure is reviewed from the light of clinical experience. It is well known that the chief difficulty of even successful operations lies in the final fixing and imperfect pronunciation, arising from the artificially formed palate which does duty as the soft palate. To lessen this defect, Mr. Mason has a specially devised operation. The monograph is very practical and interesting, and is frankly written.

## SELECTIONS FROM JOURNALS.

### THERAPEUTICS.

**EXOPHTHALMIC GOITRE CURED BY GALVANISATION OF THE SYMPATHETIC.**—Dr. Ancona (*Giornale Veneto delle Scienze Mediche*) relates the case of a young girl aged 19, of habitually bad health, who suffered from exophthalmos and goitre. She was emaciated, weak, suffered from diarrhoea and frequent flushings of the face; was irritable and capricious, and unceasingly dyspeptic. Dr. Ancona proposed galvanisation of the first cervical ganglia of the sympathetic. The poles of a Stöhrer's battery were applied on each side of the neck, behind the angle of the jaw, pressing backwards the sterno-mastoid muscles. A current of ten elements was passed for a time varying from three to five minutes. After a few days, the circuit was frequently interrupted. The physiological effects observed were the following: dilatation of the pupil each time the current was closed, more marked on the side of the negative pole; slight contractions of the sterno-mastoid; scaberrhœa, with a taste of copper in the mouth; sometimes giddiness. At the end of five months, a hundred electrifications had been applied and very well borne. Arsenical treatment was added. From the beginning of the application of electricity, there was notable amelioration, and at the end of five months the state of the patient was very satisfactory. Her weight had increased by 30 lbs. Her face and mucous membrane resumed their normal colour; her eyelids regained their mobility; the thyroid gland diminished in volume; the arterial pulsation ceased to be visible; the impulse of the heart became regular; the pulse fell; menstruation became regular; digestion was restored; and strength returned.

**GLYCERINE IN INTERNAL HÆMORRHOIDS.**—Dr. David Young of Florence reports (in the *Practitioner*) five cases in which marked and permanent benefit followed the internal administration of glycerine in doses of from two to three drachms, in water, night and morning. He says that the cases seem to show that we may be able to add glycerine to our list of palliatives for this troublesome malady. There are many patients who will not submit to surgical interference, and others—as, for example, consumptives in advanced stages of their disease—to whom one would scarcely recommend it, so that we are glad to welcome any means which would alleviate such a distressing condition. Not the least recommendation of this plan is, that it is both easy and pleasant, and probably also, especially in the case of phthical patients, beneficial in some other respects. None of the patients to whom he has given it have experienced any difficulty in taking it; and, when the sweet taste is an objection, he usually orders a little lemon-juice to be added to each dose.

**ERGOT IN CYSTITIS.**—Dr. Satterthwaite of New York (*New York Medical Journal*, April 1878) warmly recommends the use of fluid extract of ergot, in doses of one drachm three times a day, in cystitis with stricture or enlarged prostate.

**BROMIDE AND CHLORIDE OF POTASSIUM.**—It having been suggested by Dr. Binz of Bonn that the sedative effects of bromide of potassium are largely due to the potassium, and that possibly chloride of potassium might show similar therapeutic effects, Dr. Seguin has made a comparative trial of the chloride in the treatment of epilepsy alongside of the bromide. The results were conclusive as to the value of the bromide, which reduced the attacks by seventy per cent.; while, in a number of patients treated consecutively by the bromide and chloride, it was found that the latter increased the number of attacks by eighty per cent. The chloride contains a larger amount of potassium than the bromide.

**TREATMENT OF BOILS BY ARNICA.**—Dr. N. Planat has adopted (*Journal de Thérapeutique*) the use of arnica in all cases of superficial acute inflammation, as boils, angina, erysipelas, etc. He states that arnica cuts short all furuncular eruptions, except those accompanied by diabetes, with remarkable promptness. For external use, he employs a mixture of extract of fresh arnica flowers, ten parts; honey, twenty parts. If this be too liquid, he adds lycopodium. The mixture is applied to the inflamed part and covered with oiled silk. Equally good results will be obtained in the same cases by the internal administration of tincture of arnica in doses of twenty-five to thirty drops every two hours. M. Planat adds that the extinction of the furuncular eruption is so rapid that it seems impossible to deny a specific elective action.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 1ST, 1878.

UNIVERSITY INFLUENCE ON METROPOLITAN  
MEDICAL TEACHING.

THE Report which was presented by the Annual Committee to the recent meeting of Convocation of the University of London, and the resolutions which were then carried, though, we believe, of great value to the University in all its faculties, are of peculiar interest to our readers from their important bearing on medical education.

It is, perhaps, not surprising that this should be the first serious proposal for uniting the various medical schools of London by something like co-operation and mutual support, when we remember that our present schools of medicine are scarcely fifty years old. The education of the "general practitioner" up to very recent times was not for a profession, but for a trade. He was apprenticed to a member of the craft, who taught him how to prepare and mix medicines, and to treat ailments much as a modern druggist treats them over the counter on Saturday evenings. The more ambitious apothecary and the "surgeon", after finishing their apprenticeship, came to London to "walk the hospitals" and learn a little anatomy, much as our present graduates spend a year or more in Paris or Vienna before settling to practice. Physicians could only carry on the higher medical studies at Edinburgh, as they had in a previous generation at Pavia or Leyden.

In the vast improvement of the last thirty or forty years, the University of London has borne a large and honourable, perhaps the largest, part. Not only have older universities been stimulated to comparative activity, but the standard of examinations at the Colleges of Surgeons and of Physicians has been raised by the example of Burlington House, or by the introduction into the examining boards of men who had themselves taken London degrees.

Examinations, however, after all, are chiefly valuable for their influence on education. Even as a bare safeguard to the public, as the mint-stamp, a diploma is really worth what it testifies to a man's knowledge and capacity in his practice, and not to what he happened to know on the day he was examined. Hence the obvious importance of proper training and practical familiarity with medicine; indeed, evidence of this, in the shape of dissection and of attendance in the wards, is required by every licensing body whose diploma deserves respect.

To meet the demands of the higher examinations, and especially of the University, the teaching in our London schools has been revolutionised during the last twenty years. The tutorial system of Oxford and Cambridge has become firmly established, laboratories have been opened, and practical classes of all kinds have been instituted. The great medical schools of London are not mere hospitals for clinical instruction, but scientific workshops for the study of anatomy, histology, toxicology, physiology, and pathology. Their museums and laboratories (maintained solely by students' fees) supply original work which may compare in quality, though not in amount, with that of the State-supported universities of Germany and the richly endowed colleges of Oxford and Cambridge. That voluntary medical associations, left entirely to their own management and their own resources, should

have taken so liberal and broad a view of the needs of medical education, and attained such a measure of scientific efficiency, is most honourable to the profession. We may well be proud of the unendowed researches which are associated with the names of Sanderson, Rainey, Beale, Pavy, A. S. Taylor, Russell, Brunton, and a score of younger histologists, physiologists, and chemists.

But, while so much has been done, the scientific position of the medical schools of London is far from what it should be. In the minor schools, the appliances for the study of even the more important subjects above mentioned are naturally inferior to those of larger and richer institutions. Even in the best, there is no physiological laboratory which can compare with those of the Collège de France, of Leipzig, or Berlin, or Bonn, or Cambridge; scarcely any with those of Edinburgh, Glasgow, or Manchester, or with those of the second rank in Germany. And the sciences of less immediate and paramount importance to medicine—physics and chemistry, zoology and botany—are confessedly taught in an imperfect and, so to speak, provisional fashion.

A German critic once said that every English physician began by teaching botany; and it is true that in every medical school we find several of the younger members of the staff compelled to lecture (often without payment) on subjects of which they have moderate knowledge, to a small class, and with naturally only moderate success. How much better it would be for subsidiary subjects like botany and comparative anatomy, hygiene and forensic medicine, or even pathology or physiology, to be taught by some mutual arrangement which would give large classes, and enable men to undertake the subjects for a lengthened period and with far greater interest and success!

The chief cause why, in most London schools, botany is not taught as in Edinburgh, and comparative anatomy as at the College of Surgeons, and chemistry as at Manchester, is that there is no attempt at co-operation and no central body to take up neglected subjects. London could well support half a dozen anatomical schools of the first class, three or four physiological laboratories, and a single chair of zoology; but cannot efficiently support eleven of each with the necessary laboratories and museums and libraries.

Even in purely professional subjects, the London student's education is too narrow. A man may pass his four or five years of diligent work, and yet have never heard a lecture by Paget, or gone round the wards with Hilton, or seen Fergusson operate, or known Jenner and Lister and Murchison and Wilks better than he knows Trousseau and Billroth and Virchow.

The body which can from its position best foster this desirable organisation of medical education in London is the London University. It might arrange to receive certificates from joint-lecturers when classes are small, and might itself undertake the teaching of others. Every London student of medicine would then, beside the peculiar advantages his own school would offer, have the privilege of sharing in the lectures, the libraries, museums, and laboratories, which would be common property. That some such reform is needed has long been felt, and, if wisely and cautiously begun, would find more support than jealousy from the several schools. The Report to which we have referred quotes the following apposite passage from a letter by Mr. Savory, which appeared in these columns.

"I think all must admit that the usual mode of teaching anatomy, physiology, chemistry, and botany in our medical schools is very far from being satisfactory. With the exception of two or three of our largest schools, the classes are too small to afford the least encouragement to any teacher. If, instead of having the classes on these subjects split up among a number of small schools, the natural sciences were all taught at one place" (or "at some one or two central colleges") "it is not difficult to foresee that the gain to our students would be immense. The classes would be so large that the services of the best men could be secured for teaching, and the appointments would be so valuable that they would be earnestly sought for their own sake."

We hope shortly to direct attention to the second and not less important part of the Report to Convocation, which deals with the more advanced studies in medicine (and science generally), and the relation of the University to these.

### MEDICAL REFORM.

THANKS, less to the representations of the General Medical Council than to the independent efforts of the profession and of the British Medical Association, aided specially by the English medical authorities, by Trinity College, Dublin, by the Irish College of Physicians, and by the Irish Medical Association, the Lord President has at length yielded to the arguments in favour of the compulsory establishment of a conjoint board of examination in each division of the kingdom, by which an examination in the three great branches of the profession—medicine, surgery, and obstetrics,—will be imposed on every one who seeks to be placed on the *Medical Register* as a regularly qualified practitioner.

In the Bill of the Lord President as first introduced, there was no provision for the introduction of direct representatives of the profession in the General Medical Council, nor for the compulsory establishment of the conjoint scheme—two principles to which the Association was thoroughly pledged. The Bill was ordered to be printed on March 19th, 1878. On Monday, April 1st, immediately before the Easter recess, some members of the Medical Reform Committee were granted an interview with the Lord President, who listened with the most patient attention to their representations. They expressed their deep regret at the omission of all notice of the profession in the composition of the Medical Council, and stated how general was the demand on the part of the profession for some voice in its proceedings by the addition to it of representatives elected by the profession, who would have no private or corporate interests to watch over, and would, therefore, be free to balance the present overwhelming numbers of university and corporation representatives, whose clashing interests had for twenty years successfully obstructed medical reform. It was mentioned that such representatives would give the profession more confidence in the Council than at present, and smooth down any differences that might exist or arise between the Council and the profession, while adding to the knowledge of the Council in respect of the needs of the profession in sanitary requirements, medical education, medical jurisprudence, and Poor-law medical relief. The almost unanimous demand of the profession for direct representation, persisted in ever since the first agitation for medical reform, was also referred to as one great motor in the withdrawal of the Bill of the Marquis of Ripon in 1870, and the belief was expressed that the opinion of the profession in this respect was in no degree changed. The correctness of this avowment has been strikingly corroborated by the fact that the canvass of the profession has yielded only 121 replies in the negative, against 5,075 replies in the affirmative, to the question of direct representation.

With regard to the permissive character of the Bill, as it then stood, the deputation also made the strongest representations, and deplored the fact that so strong a Government should commit itself to such half-measures, when there was really a general concordance of opinion in the profession, as distinct from the corporations, in favour of a compulsory conjoint scheme to be made equally operative and binding in each division of the kingdom.

The Lord President, in introducing his Bill before the Easter recess, solicited communications from all who might be interested in the subject, and received numerous deputations. In this manner, his Grace was led to make certain concessions, which it was hoped might prove an acceptable compromise. It was suggested, in lieu of the permissive character, that it should be made compulsory on all the medical corporations of each division of the kingdom to form a conjoint scheme, leaving it to the universities to come in if they thought fit; in fact, leaving the Scotch and Irish universities free. This suggestion was carefully considered by the Medical Reform Committee of the Association, and was condemned as unsatisfactory, inasmuch as it would be a tempta-

tion to some of the universities to undersell the combined corporations. The English universities and various corporations and societies also objected; and, on May 24th, the Lord President, on the motion for going into committee on the Medical Act (1858) Amendment Bill, announced "that he must ask their lordships to allow him to amend it so as to make a conjoint board for each of the three portions of the United Kingdom compulsory". This great result has been brought about in the face of the most uncompromising opposition on the part of the universities and corporations in Scotland and of the representatives of the College of Surgeons and Queen's University in Ireland. Thus another of the four great principles for which the Association has unswervingly contended is likely to be established, leaving only one remaining principle—the representation of the profession in the General Medical Council—to be struggled for.

Under the present Medical Bill, the Council will be granted greater and more important powers than it has hitherto possessed. The whole future of medical education and of the profession is to be confided to it, and will remain in its hands, if its anomalous and vicious composition be not modified while the Association and the profession, to whose efforts the country is mainly indebted for the abolition of the discreditable competition which has hitherto existed in the bestowal of licences to imperfectly qualified men to practise that profession on which, above all others, the lives and welfare of the community hang—that Association and that profession to which this great work is mainly due are alone to be excluded from any part, any voice in the Council which is to rule their destinies, and which they virtually called into existence.

The promise of representation in the Council was distinctly made to the Medical Reform Committee of the British Medical Association before the passing of the Medical Act of 1858. The demand for it by the Association on the part of the profession, and by the profession, has been for several years and repeatedly placed before the General Medical Council and before different Governments.

The demand has been endorsed by numerous members of the legislature, by several of the medical corporations, and meets with general acceptance from the outside public. Under these circumstances, it is truly unfortunate that the propriety even of the demand has not been deemed worthy of serious discussion in the General Medical Council. The Council may not deem its own constitution matter for its own consideration, but to many it seems incomprehensible, to all it must appear strange, how members of that Council can maintain that they represent the profession, when they thus turn a deaf ear to this oft-urged demand, and, in doing so, place themselves in direct antagonism to the general body of the profession which they profess to represent.

As in every body of men, so doubtless, in the General Medical Council, the members vary in mental power, in attainments, in administrative capacity, in soundness of judgment, and in breadth of view. Men vary in receptivity; some even are loath to change an opinion to which they have once been committed, though even they may doubt its soundness, and with such able controversy intensifies obstinacy; with such, the nominee of the Crown on the General Medical Council, generally the nomination of one man, may be set down as a representative of the profession; but the profession do not so regard him; he may possibly, in one sense, be a representative man, but he is in no sense a representative of the profession.

The body in favour of direct representation in the General Medical Council is not a small and compact body; it will yet be proved to embrace the great majority of the profession, whose claims cannot be disregarded when medical reform is at issue.

### ARMY MEDICAL NOMADS.

THE sailor is supposed to rejoice that his home is on the wave, and to feel a wild satisfaction when "the rover is free". The military service has, however, always been supposed to have the opposite desires; and the medical branch of it has certainly more staid and homely tastes.

Indubitably the removals from station to station, and from one duty to another, to which the junior medical officers in the military service are subjected, are more than sufficiently frequent, if the personal experience that has been forwarded to us by one army surgeon is to be taken as a sample of what generally happens in this respect. The inconvenience and expense with which changes of the kind mentioned are attended of course become increased when the medical officer is married, as appears to have been the case all along with the surgeon who has sent us a diary of the moves he has had to make since his entry into the army; and when, in addition, serious illness is contracted through the fatigue which the officer endures, or through the unhealthiness of a station to which he is sent, and he is placed on half-pay in consequence, it may readily be understood that his disappointment and vexation will become greatly intensified. As the writer desires that neither his name nor his position should be published, we are precluded from quoting his numerous marches and changes of station, and the various charges he has held both in England and in foreign stations during his comparatively brief career of four years in the medical service of the army. On reading the account of them, however, it seems difficult to say how moves of the kind indicated are to be avoided. Marches of troops and of relatively small detachments of them from place to place are of almost daily occurrence as part of the military arrangements, and of course medical officers must accompany them; while the temporary vacancies which frequently occur in local medical charges, from the illness, or absence on private affairs or from other causes, of the medical officers holding them, must be filled up by despatching other surgeons to the stations where the gaps have happened to take place. All that seems practicable to be done in the way of lessening the inconveniences which such moves may entail, is for proper steps to be taken to ensure that no one medical officer shall have an undue share of these duties thrust upon him; that each available surgeon shall fairly take his turn in performing them. That this fairness is carried out in practice, must depend upon the administrative officers who have to direct the medical arrangements of the districts or foreign stations in which the needs arise. Perhaps the most marked difference between military and civil practice is the fact of the one being local and stationary, while the other is essentially movable. To some men in the early years of life, frequent changes of scene become sources of pleasurable excitement, and equally the performance of routine duty in the same station a source of *ennui* and irksomeness from its monotony. When family ties exist, however, so many circumstances causing trouble and expense attend each change of place and sphere of duty, that it is easy to understand how far more desirable a settled position becomes to the medical officers who are subjected to them. The question, then, arises, whether a military commission, involving as it does an essentially wandering life, is a suitable one to be held by a married surgeon, or, at any rate, by a surgeon who is married at the time of entering the army or during the early years of service, while he still remains in the junior ranks. It is to be feared that however much the objectionable circumstances, if they be regarded as such, arising from the unsettled nature of military life, may be lessened by judicious and impartial administration, that there must always remain to the married army surgeon in the junior ranks a considerable amount of inconvenience both to himself and his family from the unavoidably movable character of the service in which his professional functions have to be discharged.

It will have been noticed that His Royal Highness the Prince of Wales was absent through indisposition from the Queen's Parade on Saturday morning last. We are happy in being able to state that the cause was a bad cold, from which he has now recovered.

M. AUGUSTE OLLIVIER read a paper at the Academy of Medicine on May 14th, entitled a Contribution to the History of Spinal Gout. He had observed a case in which there was an infiltration of urate of soda on the external surface of the spinal dura mater.

THE House of Commons, on May 23rd, approved the motion of Sir J. McGarel Hogg to discharge the order for the second reading of the Metropolis Waterworks (Purchase) Bill.

THE appointment of Dr. Francis Reid, Chief Medical Officer of the island of Mauritius, to the Order of St. Michael and St. George of the Third Class or Companion, was announced on Monday last.

WE are glad to learn that, on the application of Dr. Rogers, the proprietors of the *Graphic* have sent a large supply of drawings to be hung round the walls of the Westminster Union Schools on Wandsworth Common.

A VERY sad case of death from hydrophobia has occurred at Crewe. A little boy aged about five years, son of the Baptist minister at Crewe (the Rev. F. J. Greening), was, it appears, bitten by a rabid dog in the neighbourhood of his own home three months ago. After suffering for three days, the poor little fellow expired in great agony.

A NEW public recreation ground at Sydenham has been purchased and opened. The land devoted to this purpose is seventeen acres and a half in extent, and cost £8,500.—A new park, acquired by the Bradford Corporation as a recreation ground for the districts of Great Horton and Little Horton, was opened on Saturday by the mayor (Mr. B. Priestley). The park, which is about forty acres in extent, is the third public recreation ground in the borough.

THE London and Provincial Supply Company (Limited) was recently fined, at the Bloomsbury County Court, at the instance of the Pharmaceutical Society, £5 for selling poisons without a legal qualification to do so. The defence set up was that the Company employed a properly qualified chemist to dispense the drugs.

THE Crown Princess of Germany visited the Institution for Nurses for the Sick Poor, Bloomsbury Square, on Thursday, May 23rd, and was received by the lady superintendent Miss Florence Lees, and her sister Miss Henrietta M. Lees. All the ladies, both the nurses and the probationers, were personally presented to the Princess, who expressed herself as much impressed with the usefulness of the institution, as creating a new and kindly link between the two great classes of society.

At the meeting of the Royal Medical and Chirurgical Society this week, Dr. Gowers showed a new form of sphygmograph, designed for use either as a cardiograph or a sphygmograph. The special feature is, that the increase of pressure is obtained by sliding a second spring down over the first, and the extent to which this second spring is moved at once regulates and indicates the pressure. The position of the end of the spring indicates the pressure in ounces. The spring is moved by means of a rack and pinion, and can be adjusted from either side of the instrument. Tracings, both sphygmographic and cardiographic, were shown; and amongst the latter was a tracing from the pulmonary artery and the left auricle.

IN counselling the Nottingham Committee, who have undertaken to defend the rights of the profession and the public, and to suppress irregular and unqualified medical practice, by carrying on the case of the Apothecaries' Company v. Shepperley through the higher courts, we advised that, in addition to the publication of the appeal to which we had the pleasure of giving publicity, an application should be made for a grant to the Committee of Council of the British Medical Association and to the Branches. It will be seen with satisfaction that the Committee of Council have granted the sum of £25; and other grants have also, we believe, been made from the funds of the Branch Councils. The case is one of considerable importance as a test case, and will need to be well argued. It is understood that the prescribing chemists feel that this is the last stronghold of their position, and will spare no expenditure of trouble or funds to endeavour to defeat or reverse the effect of the decision already given against them.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ALL those Fellows of the Royal College of Surgeons whose addresses in the United Kingdom are known to the Secretary have received notice that the annual meeting of Fellows will take place on July 4th, at two o'clock, for the election of three members of Council of the College.

## THE CONVICT CHANTRELLE.

A DEPUTATION from Edinburgh waited recently upon the Home Secretary to present a memorial signed by Dr. Sutherland and Mr. Edgar Wetton, praying for the reprieve of E. M. Chantrelle, who is lying under sentence of death for the murder of his wife by poison. The Home Secretary has replied that he can see no reason for interfering with the ordinary course of the law.

## HOSPITAL REFORM.

SIR SIDNEY WATERLOW informed the Committee of the Hospital Sunday Fund last Wednesday that a committee of the treasurers and trustees of the various hospitals had been formed, and that a meeting is to take place at St. Bartholomew's Hospital in a few days to discuss the question of the abuse of the out-patients' departments of hospitals. He trusted that the result would be to lessen the evil, which is now acknowledged to have grown to the most iniquitous proportions.

## THE SURGICAL AID SOCIETY.

WE are informed that the Surgical Aid Society, through its recognised officers, has had an interview with the Distribution Committee of the Hospital Sunday Fund, and expressed its inability to alter the present most objectionable rule of the society, which compels all poor applicants for relief to beg all over London for letters to cover the cost of their instruments and appliances. For inability, we are fain to read unwillingness.

## MORTALITY OF IMBECILE CHILDREN.

WITH reference to our annotation on this subject, in our last issue, we have been favoured by Dr. Beach with a return, both of the ages of the inmates of the Clapton Asylum on 31st December last, and of the ages of the decedents during 1877, classified in similar groups of ages. If similar facts were to find place in the annual reports of all kindred institutions, a valuable contribution would thus be made to our knowledge of the effect of congenital idiocy upon rates of mortality, and it would be possible to compare the rates of mortality in different institutions, and the results of different modes of treatment. It appears that, of the 350 inmates of the Clapton Asylum at the end of last year, 5 were aged under five years, 92 between five and ten years, 171 between ten and fifteen, 72 between fifteen and twenty years, and 10 were aged upwards of twenty years. The age distribution of this population would, at the English life-table rates of mortality, give a *normal* annual rate of mortality equal to 7.6 per 1,000; this *normal* rate affords the true standard of comparison for ascertaining the excess-rate of mortality among the inmates of the institution, due to their imbecility, and abnormal physical and mental condition. The numbers in this asylum are too small for the results of a single year to afford trustworthy rates of mortality at the several groups of ages; it may be noted, however, that the rate was equal to 65.2 per 1,000 among the inmates aged between five and ten years, and 46.8 between ten and fifteen; while the life-table rates are 9.6 and 5.2 per 1,000 at the same ages. The proportional excess of mortality was greater between ten and fifteen years than either at the earlier or subsequent groups of ages.

## VACCINATION.

SIR THOMAS CHAMBERS presided this week at a public discussion between two gentlemen on the subject, "Is vaccination worthy of national support?" There can, of course, be no disadvantage, but, on the contrary, much advantage to the public from the discussion of this question, provided care is taken that the persons who discuss it are adequately representative of the fullest knowledge of the question, and

are themselves recognised authorities. In the present instance, the discussion appears to have been very imperfectly conducted; and Sir Thomas Chambers, in his introductory remarks, seemed to be totally unaware of the official reports already laid before Parliament on the subject, since he said that vaccination had not been before the House of Commons in a serious form, and even went to the extent of adding that it was for the benefit of both sides that the whole facts should be known. There is no serious objection to members of Parliament uttering platitudes of the sort; but, when a person in the position of Sir Thomas Chambers takes the chair at a discussion of a question on which the public mind has been much agitated, it is his duty, if he make any observations at all, to make himself fairly acquainted with the existing state of knowledge, otherwise he has no claim to the position of chairman, and lends his authority to a proceeding which is dangerously fallacious. In this case, it is perfectly clear that he has done more harm than good by not mastering something of the facts upon which he professed to make a speech. As the representative of a borough containing, perhaps, a larger number of educated medical men than any other, we think he can scarcely be said to have shown an intelligent perception of his public duty or of his just relation to his educated constituents.

## VACCINATION AND INFANT-MORTALITY FROM SMALL-POX.

MR. WILLIAM HUME-ROTHERY, the President of the "National Anti-compulsory Vaccination League", has recently been afforded the opportunity of publishing, in a comparatively new weekly publication entitled *Social Notes*, an article in which he summarises the grounds on which he bases his strenuous opposition to vaccination in general, and to compulsory vaccination in particular. The article in question is a fair sample of anti-vaccination literature; it abounds with reckless assertions and unsound deductions, which are used as arguments to justify denunciation, in the most uncompromisingly strong language, of the "worthless and pernicious practice" which threatens "the utter ruin of the physical health of the nation". Mr. Hume-Rothery's assertions may be divided into two classes: he asserts that vaccination is injuring the physical health of England, and indeed of the civilised world; and he also asserts that vaccination has not reduced either the prevalence or the fatality of small-pox. With regard to the after-effect of the vaccine disease upon the human being, assertions may be easily made, as they can neither be proved or disproved in a scientifically satisfactory manner; it can, however, be proved that the national death-rate, both at all ages and among infants, has declined since compulsory vaccination was ordained, from which it may be inferred that the effect of vaccination upon health cannot, at any rate, be very disastrous. Mr. Hume-Rothery's article is full of deductions which are as shallow as they are utterly misleading to those who have not the opportunity and capacity for estimating them at their proper value. We propose, on the present occasion, to notice one of his assertions, which he afterwards uses as an argument against vaccination. Alluding to the fact that, in 1875, only nine hundred and fifty deaths from small-pox were registered in the whole of England and Wales, he adds: "Yet one hundred and forty-two of these were of infants under one year of age, most of whom must have been vaccinated and have died—of small-pox, he it remembered—within nine months after their vaccination." If this were not so serious a subject, the boldness of this "must have been vaccinated" would be amusing; it is difficult, however, to denounce in language too strong the attempt that is thus made to throw dust in the eyes of the ill-informed as to vaccination and small-pox statistics. The Local Government Board Reports show that more than forty thousand children born in England and Wales in 1875 escaped vaccination, without counting those that died before attaining the vaccination age, among whom doubtless some died from small-pox. Let us look a little more closely into the ages of those one hundred and forty-two infants who died in 1875 from small-pox under one year of age. We find that sixty-five died under three months of age, thirty-four between the ages of three months and six months, and forty-three were aged

six months and less than one year. Putting on one side our moral conviction that not one of these one hundred and forty-two infants had been successfully vaccinated, we should like to hear Mr. Hume-Rothery's explanation of the fact that, of the one hundred and forty-two, ninety-nine were aged under six months, and only forty-three between six months and one year. Our explanation would be that the proportion of unvaccinated among the infants aged under six months is much larger than among those aged between six months and one year; hence the far-greater mortality from small-pox. If it were possible to ascertain the number of small-pox deaths in each of the first twelve months of life, we should probably find the number steadily decline from the first month, when practically all infants are unvaccinated, to the twelfth month, at the end of which only five per cent. would be found unvaccinated, if we may rely upon the Reports of the Local Government Board. As at least eighty thousand infants *per annum* either escape vaccination or die before they reach the compulsory vaccination age, the assertion that most of the one hundred and forty-two infants who died from small-pox under one year of age in 1875 "must have been vaccinated" is not only unfounded, but inexcusable. The figures for 1876 are still more remarkable. During that year, two hundred and eighty-seven deaths from small-pox, of infants under one year of age, were registered, including two hundred and twenty-nine aged between birth and three months, and only sixty-three aged between six months and one year. We can suggest no probable explanation of the far greater fatality of small-pox in the first than in the second half-year of life than the larger proportion of the unvaccinated among the younger infants. We know, indeed, no stronger argument in support of the protective influence of vaccination than the rapid decline in the mortality from small-pox among infants after they attain the age when vaccination becomes general. It is true, as Mr. Hume-Rothery states, that large numbers of children aged under five years have died from small-pox in England and Wales since vaccination became compulsory. This fact, however, instead of proving "beyond a doubt that vaccination is worthless", as Mr. Rothery recklessly asserts, only really proves that a certain proportion of the forty thousand children *per annum* who escape successful vaccination fall victims to small-pox through the ignorance or neglect of their parents, fostered by the blind and mistaken zeal of this and other anti-vaccinationists.

#### THE ARMY MEDICAL DEPARTMENT.

A CORRESPONDENT of the *Times* writes: "Were you to propose that each regiment should have one medical officer, a surgeon-major, attached to it permanently, and on its being raised to a war footing that the commanding officer should obtain the second medical officer (or third and fourth, if you please), the difficulty of providing recruits for the medical service of the army would be at an end." The proposal, so far as it goes, is not a bad one; but neither it nor any other proposal will be of the slightest avail so long as the medical officers are not treated with kindly and gentlemanly consideration—at least with simple justice. The scheme for which any hope of success can be entertained, can only be one which has for its object the raising of the army medical officer to the honourable position he has a right to occupy in the public service.

#### VENTILATION.

THE Subcommittee appointed at Leamington to test the relative performances of ventilating cowls, which have heretofore been recommended for ventilation by exhaustion, have reported the result of their investigation to be as follows. The Committee consisted of Captain Douglas Galton, C.B., F.R.S., Mr. Rogers Field, and Mr. William Eassie.

"The Subcommittee appointed at Leamington to test the ventilating exhaust cowls beg to report that they have given the matter their most careful attention, and carried out at the Royal Observatory, Kew, an elaborate series of about one hundred experiments on seven different days, at different times of the day, and under different conditions of wind and temperature. After comparing the cowls very carefully with

each other, and all of them with a plain open pipe as the simplest and, in fact, only available standard, the Subcommittee find that none of the exhaust cowls cause a more rapid current of air than prevails in an open pipe under similar conditions, but without any cowl fitted on it. The only use of the cowls, therefore, appears to be to exclude rain from the ventilating pipes; and, as this can be done equally, if not more efficiently, in other and simpler ways, without diminishing the rapidity of the current in the open pipe, the Subcommittee are unable to recommend the grant of the medal of the Sanitary Institute of Great Britain to any of the exhaust cowls submitted to them for trial."

The several cowls experimented upon will be on view at the Royal Observatory, Kew, from June 3rd to 5th inclusive, between the hours of one and three P.M.

#### ARSENICATED VIOLET POWDER.

ON Friday, May 24th, at the Epping Petty Sessions, Henry George King, wholesale chemist, of Abbott Street, Kingsland Green, was charged with having, on February 18th, at Loughton, in Essex, feloniously killed one Eliza Sear. A second summons charged him with having, on January 1st, 1877, and divers other days, unlawfully, falsely, fraudulently, and deceitfully sold and delivered, and caused and procured to be sold and delivered, to divers persons residing in the said parish, quantities of violet powder, consisting of large quantities of white arsenic and other ingredients; and that he caused and procured the said poisonous powder to be so applied to Florence and Sarah Martin, William Ernest Mead, Eliza Sear, Alfred Harrington, and other children; and that he, well knowing the said violet powder to be poisonous and to contain large quantities of white arsenic, caused it to be applied, whereby their bodies became disordered and their health injured and endangered. Mr. Poland, instructed by the Treasury, conducted the prosecution. Mr. Poland, in his opening statement, said he appeared to prosecute the defendant for manslaughter, and also for the common law misdemeanour of selling quantities of violet powder containing poisonous substances and intended to be used on the bodies of children of tender years. The defendant in his circulars described himself as a "wholesale druggist, dry-salter, and general packer", and in the list of articles sold by him there was, under the heading of "powders", a description of penny packets of violet powder, the wholesale price of which was stated as being 6s. and 7s. per gross. In the same circular, he mentioned the fact that he was the manufacturer and packer of insect powders. The violet powder was described on the wrappers as "H. G. King's Superfine Violet Powder, warranted free from grit. For the nursery". The defendant had been for some time past in the habit of supplying Miss Grou, who keeps a grocer's shop at Loughton, with these violet powders. She had in her possession a stock of the violet powder, and in February 1877 Mr. Nottage, a grocer in the same village, purchased from her three dozen of the powders, which he sold to persons applying for them. By the evidence, it would be shown that the packets purchased at these two shops had most injurious effects when applied to the bodies of children. The attention of the medical men in the district was attracted to what appeared to be an epidemic among the children, and it would be shown that, in twenty-eight cases where these powders were used, twelve or thirteen deaths had resulted. A Mr. Deacon purchased one of the powders, and, seeing the effect it had on his child, he came to the conclusion that it must have contained matter of an injurious nature; consequently, he directed his servant to purchase another packet, which, on being subjected to analysis, was found to contain 25 per cent. of arsenic. He made a second purchase, and, when that was analysed, it was found to contain 28 per cent. of the poison. Mr. Deacon communicated with the Home Office; but in the meantime information had been forwarded to the Local Government Board, and a gentleman was sent down by them to investigate the matter. From consultations which he had with Drs. Fowler, Roberts, and other medical gentlemen residing in the neighbourhood, he came to the conclusion that the injuries to these children, and the deaths of others, were due to the application of these violet powders containing such large quantities of poison. In most cases, the powder had unfortunately been thrown away; but in five

cases the remaining portion had been preserved. The learned counsel then went on to state the nature of the evidence which would be adduced and which will be found appended, and stated that, as soon as the authorities of the Treasury had obtained an analysis of the powders, the following letter was sent to the defendant.

"Treasury, April 23rd, 1878.

"Sir,—I have received from the Secretary of State directions to take proceedings against you for manufacturing and selling 'superfine violet powder', which is supposed by its use to have caused the deaths of some infants and the serious illness of others. This powder has been found upon analysis to contain a considerable quantity of white arsenic, the percentage of such arsenic being in three cases 50.34, 51.40, 48.94. I think it right at once to instantly warn you against selling any violet powder containing arsenic or other poisonous ingredients, and also without delay I require you to give notice to all persons to whom you have sold this powder that they are at once to stop the sale, and where they have parted with any of it to give notice to the purchasers and prevent its use. The powder which has been analysed was purchased since early in March 1877, at two grocers' shops situate one in the High Road, Loughton, and the other at Baldwin's Hill, Loughton. You have probably heard of the serious result of the use of the powder in the neighbourhood of Loughton and Epping; but I think it right to give you this notice, in order to prevent further mischief arising from the sale.—I am, etc.,

"W. H. HODGSON."

"Mr. H. G. King, superfine violet powder manufacturer, 14, Abbott Street, Kingsland Green, London."

The defendant took no notice of the letter until he had been served with the summons in the present case, and then he sent the following letter to the Treasury.

"14, Abbott Street, May 21st, 1878.

"Sir,—On receipt of your letter, I immediately called on all parties I was in the habit of supplying with violet powder, and took away the stock they had in hand and destroyed it. I only ended my unceasing search yesterday. I have to express my great regret at the occurrence, as I have never dealt in arsenic, and had no knowledge of such being on my premises.—Yours, most respectfully,

"H. G. KING.

"W. H. Hodgson, Esq., solicitor, the Treasury."

The learned counsel then went on to explain that arsenic, when purchased in large quantities, was cheaper than pure starch, from which violet powder was usually manufactured. Evidence was adduced to bear out the opening statement of counsel, and the case was adjourned for a week.

#### MR. GLADSTONE AT THE EAST LONDON HOSPITAL FOR CHILDREN.

THE anniversary dinner of this charity was held last week in a tent erected in the grounds of the Hospital at Shadwell. The desire of the Committee was to bring people to see their hospital, and not merely to subscribe towards it. A visit to the well-ordered wards, and a sight of the little patients in their cots, is no doubt a sure way of enlisting that peculiar expression of sympathy on which the material and moral success of an unendowed charity like this mainly depend. Mr. Gladstone, who was accompanied by Mrs. Gladstone, kindly presided at the dinner, and between two and three hundred visitors, ladies and gentlemen, assembled to meet them. Mr. and Mrs. Gladstone, after visiting the wards, which now accommodate ninety patients, and minutely inspecting the arrangements, expressed themselves as eminently satisfied; and we are glad to congratulate the Committee of Management on the efficiency and economy of their administration. A very satisfactory report was presented; for it appears that a large number of patients have been treated, and the applications, both of in-patients and out-patients, are continually increasing; from these, the most urgent and deserving cases are admitted under treatment. The financial report shows that the average cost per bed is only about £50; this, for a children's hospital, is exceedingly low, when we consider the much greater attendance and care which sick children require, as compared with an equal number of sick adults. We were much pleased with the wards; each is presided over by a "sister" or superintendent, and there are three or four nurses, according to circumstances, to look after the thirty beds, with which each ward is provided; and a lady superintendent of nursing regulates the whole. It seems a distinct

feature, and a very noteworthy one, that young infants are admitted; we saw some babies only a few days old. We are glad the East London Hospital had the courage to supply what has long been felt as a great want in this direction, and has thus given the medical staff the opportunity of the careful clinical observation of infants. Mr. Gladstone made an eloquent speech on behalf of the hospital, and drew attention to the opportunity thus afforded of bringing the upper classes of society into personal contact with their poor neighbours. Mr. Gladstone specially pleaded for children's hospitals, referring to the importance of a healthy childhood if we would have a healthy adult population.

#### THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MR. ROYES BELL writes to us:—Will you permit me to call your attention to an inaccuracy in the order of seniority of the candidates for election into the Council of the College in your number for May 18th? I find, on referring to the College Calendar, that in the Chronological List, the names are placed as under. Membership: Mr. E. Lund, 1847; Mr. J. Wood, F.R.S., 1849; Sir H. Thompson, 1850; Mr. H. Power, 1851; Mr. J. Lister, F.R.S., 1852. Fellowship: Mr. Lister, 1852; Sir H. Thompson, 1853; Mr. Wood, May 1854; Mr. Power, December 1854; Mr. Lund, 1863.

#### HEALTH AND SEWAGE OF TOWNS.

ON Friday, May 24th, the Right Honourable J. Stansfeld, M.P., presided at the resumed conference on this subject at the rooms of the Society of Arts. The subject first dealt with was "the discharge of sewage into the sea". Sir Henry Robinson, who opened the subject, pointed out that the difficulties attending the discharge of sewage into the sea would be diminished were it not that it had a higher temperature and a less specific gravity than sea or river water, which caused it to rise to the surface; and if it were not carried seaward at once, part of the suspended solid impurities were deposited on the coast wherever there was still water and no tidal current, whilst the rest of the suspended, together with the dissolved, impurities float on the surface, and are carried backwards and forwards by every tide, decomposing and liberating gases (sulphuretted hydrogen being one of the most offensive) injurious to health and polluting the air. There had hitherto been much prejudice against chemical treatment, but it had been abundantly proved that sewage could thereby be deprived of its offensive properties by simple and inexpensive means. He suggested that this matter should be also recommended to the Local Government Board for further investigation. Mr. Alcock of Sunderland moved a resolution to the effect that, in the opinion of the Conference, the benefit to large towns of a well-devised and effective system of sewers was very often neutralised by the careless and improper way in which the house-draining in connection with such sewers were laid and connected with the soil and waste pipes of the house; that all drains intended to be connected with the sewers of the sanitary authority ought to be made by such authority; that powers as extensive as those contained in 11 and 12 Vict., c. 112—the Commissioners of Sewers Act—with corresponding duties, should be conferred and imposed upon all local sanitary authorities, including those in the metropolis. After a long discussion, the motion was carried. The President, in summing up, spoke in favour of enlarging the area of the Local Government Board, by which they would ennoble the work, and so attract the best men. Referring to the Local Government Board itself, he said that, like other departments of the State, it was admirably served. The question to his mind was not the fitness of the men, but the organisation of the department. There seemed a tendency in all the Government departments to become merely secretarial departments, and they were full of mistrust of what was called "administration". The permanent head of the Local Government Board ought to be an organiser, not a secretary. A resolution was then passed recording the opinion of the Conference that further legislation was needed, especially with regard to the constitution of county boards, with a view to strengthening the

Local Government Administration, and authorising the president, in conjunction with the Council of the Society, to be the exponent of its views on the subject, etc. A vote of thanks to the President closed the Conference.

#### UNREPORTED SMALL-POX.

AT the last meeting of the Walthamstow Local Board, Mr. Wragg called attention to the fact that during the last few weeks, there had been no fewer than twenty-two cases of small-pox at St. Mary's Roman Catholic Orphanage, while only one or two cases had been reported to the Board. Mr. Horner also remarked upon the fact that he had never been acquainted with the fact of there having been so many cases. The chairman suggested that a committee should be formed to consider as to the advisability of erecting some place in the parish as a disinfecting-room, considering that there were so many cases of small-pox in the neighbouring parish of West Ham, and that there was no accommodation of the kind to be obtained at the hands of the guardians. After some discussion, it was agreed to allow the matter to stand over till the next meeting.

#### COUNTER-PRESCRIBING.

THE Medical Defence Association has added to its many claims to the gratitude of the public and the profession by the recent prosecution, in which it has once more struck a blow at the dangerous practice carried on by chemists of doctoring the ailments of the poor. We refer to the case of the Society of Apothecaries v. Wiggins, heard last week before Mr. Justice Field. The action was brought to recover four penalties of £5 each, which were claimed under the twentieth section of the Apothecaries' Act, 1815, from the defendant, who is a chemist at Bermondsey, for having, as was alleged, practised as an apothecary without an apothecary's licence. The defendant is duly registered as a chemist and druggist under the Act which requires such registration. The cases in which the defendant was said to have acted as an apothecary were those of four children. In two of the cases, the children were brought to him to his shop, and he felt the children's pulses, made some inquiries as to their state, and gave a bottle of medicine, for which he charged 7d. In the two other cases, the mothers of the children called and described the symptoms to the defendant, who gave some medicine and directions. In some of the cases, the defendant advised that if the children did not get better, a medical man should be called in. In the result, it turned out that these four children were suffering respectively from bronchitis, pneumonia, scarlet fever, and convulsions. A medical man was called in in three of the cases, but the children ultimately died. It was not suggested that the treatment of the defendant was in any way improper from a medical point of view, or that he was doing anything which he had any reason to believe was wrong. The jury found, in answer to questions put to them by his lordship, that the defendant, in doing what was complained of, was acting or practising as an apothecary, and that the complaints under which the children were suffering were not such complaints as a chemist would have prescribed for before the passing of the Act. Upon these findings, judgment was entered for the plaintiffs. It is necessary to remember how dangerous are the consequences of this kind of irregular practice, how largely it is carried on, and how utterly incomplete are the guarantees which it affords for the safety of the patient or the competence of the practitioner. Chemists are secured in large privileges by Act of Parliament, and they are bound not to exceed those limits. The fact that they have to deal largely with drugs, and are supposed to possess some knowledge of their properties, invests them in the minds of the ignorant and uneducated classes with a certain mysterious semi-medical character with which is mixed up the idea that they must know what is good for all sorts of diseases; and it is for that reason that they are bound specially not to infringe upon the privileges of the medical profession, with which they have close relations, but to which they do not belong, and of which it is dangerous that they should ape the charac-

ter or assume the functions. Chemists have, however, largely assumed medical functions throughout the country; and the Medical Defence Associations started by Mr. R. H. S. Carpenter, Mr. Nelson Hardy, and Mr. G. Brown, are rendering a service to the profession and the public, which can hardly be overestimated in vindicating the dormant powers of the law by prosecuting chemists who infringe it in this respect. We suggested more than once last year that the British Medical Association should organise local committees in connection with its branches for managing such prosecutions in an uniform manner; and we are still inclined to think that such local committees would be of much public and professional advantage. Systematically conducted and guided from a centre with due discretion, very few such prosecutions would then become necessary; for were the law once adequately vindicated at different parts of the country simultaneously or nearly so, and were it well understood that a central body, having adequate local organisation, would aid by local committees to protect the public and the profession from the encroachment of these unqualified persons, the result would be that very few prosecutions would be called for. The deterrent influence of such an organisation would very soon make itself felt; and nothing could be more desirable in the interests of public health and morality. Meanwhile, we congratulate the Medical Defence Association, that with small funds and without the countenance of persons of high influence or position, they have, by independent action, vindicated the law and maintained the interests and rights of their own profession and of the public at large.

#### SCOTLAND.

THE death-rate in Edinburgh last week was 21 per 1,000. While the general zymotic mortality is low, it was observed for the first time for many months that no deaths from infectious disease was recorded in the New Town.

A YOUNG man has died in Aberdeen Infirmary from the effects of a piece of wood, five inches in length, supposed to be part of a rocket, having penetrated his skull, about an inch above the right ear.

A MELANCHOLY case of drowning occurred in the river Almond, Perthshire, last week. Dr. Duncan Whyte, a young medical man, residing with his father at Millhaugh, Methven, left home for the purpose of fishing in the Almond. As he did not return, a search was instituted next day, when his rod was found floating in the river; and, on the stream being searched, the body was discovered in a part only about eighteen inches deep. It is supposed that the deceased had fallen from a steep bank and been stunned.

#### CHARGE AGAINST A DISPENSARY MANAGER.

THE manager of the City Parochial Board Dispensary, Glasgow, who has been in that position for five years, has been sentenced to one month's imprisonment, on a charge of stealing or embezzling a quantity of liquor and medicine belonging to the institution. The accused and two young women were found in the Dispensary in a state of intoxication, though several witnesses were called to prove that he had previously borne an excellent character.

#### INSPECTION OF DAIRIES IN GLASGOW.

THE inspector reports that during the last fortnight 103 dairies had been inspected, the whole of which were fairly clean and in good order. In 40, only milk was sold; in 63, other articles besides. In 23 of the total number, the families had separate dwelling-houses; while in 80 cases they occupied apartments communicating with the shop.

#### DEATH FROM CHLOROFORM.

A CASE of death under chloroform is reported to have occurred last week in the Edinburgh Royal Infirmary, in the wards of Mr. Annandale. The patient had been chloroformed in one of the wards, and, when brought into the theatre for operation, was found to be suffering

from the chloroform. He never rallied, and died before the operation, an amputation of the leg, could be begun. Another fatal case, we are told, occurred not long since in the same institution, but in the wards of another surgeon, under somewhat similar circumstances.

#### THE EDINBURGH ROYAL INFIRMARY.

At a recent meeting of the managers of the Edinburgh Royal Infirmary, it was resolved that the services of medical and surgical officers who have long and faithfully served the institution should be recognised by honorary appointments; and, in accordance with this resolution, Dr. D. Rutherford Haldane was appointed a consulting physician, and Dr. A. Keiller consulting physician for diseases of women. Dr. John Bishop has also been appointed assistant-surgeon to the institution. This appointment was not in connection with any vacancy, but because it was thought desirable that there should be three instead of two assistant-surgeons.

### IRELAND.

At a meeting of the Governors of Waterford Lunatic Asylum held last week, Dr. W. Conolly was elected Visiting Physician, at a salary of £100 *per annum*.

IMMEDIATE application will be made by the Commissioners of Bray for a loan of £7,808 for the carrying out of sanitary works in that township.

#### THE ROYAL IRISH ACADEMY.

At a general meeting of the Academy held on Monday last, the President, Sir Robert Kane, F.R.S., himself a member of the medical profession, presented the Cunningham Gold Medal to two distinguished medical men: Dr. Aquilla Smith, King's Professor of Materia Medica in the School of Physic, and representative of the King and Queen's College of Physicians on the General Medical Council; and Dr. Allman, F.R.S., the well-known natural historian. The Cunningham Medal is the highest honorary reward by which, in Ireland, intellectual distinction is recognised, and is conferred from time to time on men selected on account of their eminent literary, scientific, or archaeological merits. Sir William Wilde was the last recipient of this honour. On the present occasion, the medal was awarded to Dr. Smith for his inquiries into Irish numismatics, by his investigations and writings on which subject he has supplied important materials for the elucidation of many obscure points in Irish mediæval history. His splendid collection of Irish coins now also enriches the Academy. Dr. Allman's claims to the honour rest upon his researches into the natural history of the hydrosora, and will be endorsed by every naturalist. Two other gentlemen received the Cunningham Medal on the same occasion; viz., Dr. Carey, for his important mathematical discoveries; and Professor Dowden, for his literary writings.

#### OBSTETRIC STATISTICS.

DR. MACNAUGHTON JONES has published his obstetrical report of the Cork Maternity Hospital for the five years ending December 1877. This dates from its foundation, five years ago; since which time, 1,611 women have been delivered. Of the labours, 1,267 were natural. The remaining 344 difficult cases are made up as follows: Difficult, 108 (including 6 force-presentation); preterm, 74; complex, 117; abortions and miscarriages, 45. The preterm labours consisted of 14 am-presentation and 60 breech and footling cases. The complex cases are made up of: twins, 34; triplets, 1; placenta prævia, 5; *post partum* hæmorrhage and retained placenta, 35; accidental hæmorrhage, 5; prolapsed funis, 16; convulsions, 5; ruptured uterus, 3; adherent placenta, 12; hydroids, 1. The forceps was applied 93 times; version was performed 17 times; craniotomy 3 times, excision twice, and hysterotomy twice. The total number of still born children at full time, from various causes, is 64. Twelve children died after instrumental delivery. The maternal deaths number 14. The forceps used

was Simpson's. Of the 93 forceps cases, one mother died from subsequent peritonitis, and seven deaths of the children resulted, though Dr. Jones is unable to say how many of these were dead before its application. Dr. Macnaughton Jones does not consider it necessary to wait for complete dilatation of the os uteri before applying the forceps. In the only instance in which the perchloride of iron was injected into the uterus, to restrain *post partum* hæmorrhage, it was attended with a successful result. Hitherto Dr. Jones has not resorted to the plan, recommended by Dr. Lombe Atthill, of injecting water at 112 deg. Fahr. into the uterus in *post partum* hæmorrhage. Such reports as this are of great value; and we are pleased to see the excellent example of Dr. George Johnston, the late Master of the Rotunda Hospital, so well followed by Dr. Jones, who took, we believe, a large part in the foundation of this useful institution.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE thirty-fifth annual report of the Council has just been issued to the Fellows of the College. During the year ending April 5th, 1878, five candidates were admitted to the Fellowship of the College, and ninety-nine gentlemen received letters testimonial; eight licentiates obtained the diploma in midwifery; fifty-six candidates for the junior class examination were rejected; and thirty-two candidates for the final examination were rejected. Two hundred and sixty-four candidates presented themselves for the preliminary examination; of these, thirty-three received first class certificates; seventy-one received second class certificates; sixty-six received pass certificates only; and ninety-four were rejected. The entire number on the lists of the College amounts to 402 Fellows and 2,914 licentiates. The Council congratulate the College on the rapid progress towards completion of the new library and museum. It would appear, however, that the financial condition of the College is not so favourable as might be wished. A large sum of money has doubtless been expended on the new buildings; but we understand that, for some time past, the annual expenditure has exceeded the College income. The income of the College from fees, dividends, and interest for the year, amounted to £3,828 18s. 6d., and the expenditure, including that on the new buildings, to £7,108 0s. 5d. Stock, to the amount of £2,663 6s., was sold out to meet this deficiency. The balance sheet shows a credit of only £170.

#### THE SMALL-POX EPIDEMIC IN DUBLIN.

THE Public Health Committee of the Corporation have supplied the following return, showing the progress of the epidemic. On March 22nd, the number of cases in all the hospitals in the city was 136, consisting of 93 acute and 43 convalescent cases. On April 22nd, the number had increased to 218, consisting of 151 acute and 67 convalescent. On May 22nd, after the lapse of a few months, the number had increased to 315, consisting of 208 acute and 107 convalescent, and there has been a further increase since that day. This shows the epidemic has been steadily on the increase, and that at no time since the outbreak had the number reached the figures returned on May 22nd. The number of cases of small-pox under treatment in the Dublin hospitals (including the temporary hospitals in connection with the two union workhouses) on Saturday last was 267, against 270 on the preceding Saturday; 94 cases were admitted during the week, being 12 less than in the previous week; 82 patients were discharged as cured, and 15 died.

#### NEW CONVALESCENT HOSPITAL FOR DUBLIN.

THE late Michael Bernard Mullins, Esq., J.P., of Dublin, who died in July 1871, left large bequests to several charities, and out of the residue of his property a sum of money for the erection and support of a convalescent hospital near Dublin, to be connected with his name. The intentions of the testator have been carried out by his trustees by an arrangement with the existing St. Vincent's Convalescent Hospital at Stillorgan, co. Dublin, by which accommodation for not fewer than fifteen patients will be provided for out of the funds at the disposal of the trustees. A large suitable building has been erected on the ground adjoining

ing the St. Vincent's Convalescent Hospital, which is under the charge of the Sisters of Charity; and these ladies have also undertaken the management of this important addition to the numerous medical charities of Dublin. Each of the wards is distinguished by a tablet, indicating that its endowment and support are owing to the charitable bequest of Mr. Mullins. The medical officers of eight of the Dublin hospitals are empowered to recommend adult patients, in course of recovery under medical or surgical treatment, for admission to the Mullins's Convalescent Hospital, without any distinction by reason of religious denomination of the person recommended. Persons recovering from contagious or infectious diseases, so long as there is any danger of contagion or infection; epileptics; and persons suffering from diseases attended with copious or offensive discharges, or such as require constant medical attendance or constant nursing, are inadmissible. The building is now completed and open for the reception of convalescents.

#### LIMERICK WORKHOUSE.

As was expected, the Local Government Board have sent a sealed order to the Board of Guardians of this Union, removing Mr. Meehan from the post of medical officer, to which he was recently appointed, and to which we referred last week. The Board subsequently considered the report of a committee recommending certain changes in the medical staff of the workhouse, which, after some discussion, was adopted. It has been decided that another resident medical officer shall be appointed at a salary of £200 *per annum*, a resident apothecary at £100, and that Dr. Barry shall be continued as the visiting physician at a salary of £75 a-year. These additional officers were necessary, as the workhouse contains a larger number of inmates than the present staff could properly attend to. The appointment of an apothecary or pharmaceutical chemist was much needed, as the Committee, recently selected to report on the condition of the surgery, stated that it was very much neglected; and described it as in an untidy neglectful state, without a tincture-press, percolator, pill-machine, etc., articles which in every well regulated pharmacy are indispensable.

#### BELFAST ROYAL HOSPITAL.

THE quarterly meeting of the General Committee of this institution was held last week, when it was reported that the Board of Management had received a further donation of £200 from the Rev. Arthur Pakenham, in memory of his late brother Lieutenant-Colonel Pakenham, towards the building of the Convalescent Home, which has reduced the debt on that building to about £800. It has been determined to set apart a ward in the Home to record this and previous donations to the funds of the charity, and to carry out the wishes of the donor in remembrance of his deceased brother. The total amount received by the treasurer from the Hospital Sunday collections was £555, being a slight increase over that of the previous year, but very far from what it ought to be in a wealthy town like Belfast. The senior resident surgeon Dr. Jefferson, having resigned, has been succeeded by Dr. O'Neill, the junior house-surgeon, whilst Dr. Clarke has been appointed in the vacancy caused by Dr. O'Neill's promotion. The untimely death of Mr. Charles Graham, resident medical officer of the Convalescent Home, was referred to in feeling terms, and a vote of condolence with his family was recorded. Mr. Graham was a young gentleman of considerable promise, and contracted the disease, of which he unfortunately died, in the discharge of his professional duties.

#### PROMPT BURIAL OF SMALL-POX PATIENTS.

THE Guardians of Rathdrum Union last week, having received a letter from the Local Government Board, recommending the prompt burial of the bodies of persons who had died of small-pox in the workhouse, it was resolved that burial in such cases should take place eight hours after the friends had received information of a death; also that, immediately on death, the remains should be placed in a coffin and fastened down till interment. These precautions are very necessary, owing to the highly contagious nature of the disease.

#### ARMY MEDICAL SERVICE.

THE following reply has been sent by King and Queen's College of Physicians in Ireland to the Secretary of State for War's extraordinary request for information as to the average earnings of civil medical practitioners:

"Sir,—I have the honour to inform you, in reply to your letter of the 27th April, which was fully considered by the President and Fellows of the King and Queen's College of Physicians in Ireland, that the College regret it is not in their power to afford any 'trustworthy estimate of the average earnings, under ordinary circumstances, of medical practitioners in civil life'. They believe, however, that, although the income of junior members of the profession derived from practice and appointments does not always exceed the pay of junior army surgeons, yet that the emoluments of those of (say) five years' standing and upwards are greatly in favour of the civil practitioner, whilst the professional prospects of the latter are incomparably superior to those of officers of the Army Medical Department. The College, however, believe that the well-founded discontent which has prevailed for some time amongst the medical officers of the army, and which has deterred candidates from offering themselves for the Service, though partly due to dissatisfaction with the rate of pay under the Warrant of 1858, is mainly to be attributed to the several causes pointed out in the memorial of the College to the Right Honourable Gathorne Hardy, dated 14th April, 1877, and the letter of the College, dated 5th April, 1878.—I have the honour to be, sir, your obedient servant,

"J. MAGEE FINNY, M.D., Fellow and Registrar.

"Ralph Thompson, Esq., C.B., Assistant Under Secretary for War."

The Faculty of Medicine of the Catholic University have also sent an able reply. They observe that the information sought for by the War Office is to be applied, so far as it can be at all approximately obtained, to a comparison of the position and emoluments of the army medical officers selected after severe competition, not with those of the average civil practitioner, but with those of the smaller and more select body of men, who, after the closest study of their profession, aim at achieving high places in it by the exercise of unwearied zeal and more than ordinary abilities. It is consistent with what is personally known to members of the Faculty individually, that of the select class of young medical practitioners thus defined, a considerable number achieve very early success, and are, within the first quinquennial period of their career, often placed in the receipt of incomes of at least £500 a-year. In the second quinquennial period, incomes ranging from £500 to £1,000 a-year, and even upwards, have been realised by able men as civil practitioners, in favourable circumstances and in good localities. It is further to be observed that, in the case of young men of conspicuous ability who enter on the career of teaching, large incomes and high distinction are often very early secured. Irrespective of the advantages of a fixed, comfortable, and healthy abode for himself and his family, the position of an energetic and successful civil practitioner in his tenth year, and thence onwards, is incomparably superior to that of the army medical officer at the same period of his career, exposed to all the risks of foreign service, in which his wife and children are involved, and in connection with which very heavy expenses are entailed upon him, for which the service provides no adequate compensation. At the more advanced periods of life comprised in the inquiry, it will be found that no comparison is fairly sustainable between the army medical officer's position on his retirement upon a guinea a-day, which dies with him, and that which a selected man of the same ability would in all probability have acquired for himself and his family, with the fruits of his labours well invested as a permanent provision for himself and those to come after him. The Faculty further observe that, if it ever be deemed advisable by the State to secure for the army the very highest class of medical ability, it will be necessary for the War Office to raise the status, including therein both rank and pay, of the army medical officer through all grades, from the Director General down to the most junior surgeon, to a degree far beyond that which now obtains.

The Council of the Royal College of Surgeons of Ireland give in their reply the average income of the Poor-law medical officers, which is, of course, independent of the earnings from other appointments and private practice. As to estimating the average amount of the latter, they have no authentic data to go upon; and would decline, with commendable dignity, making any inquisitorial inquiries.

## ASSOCIATION INTELLIGENCE.

## YORKSHIRE BRANCH.

THE annual meeting of this Branch will be held at the Medical School, Leeds, on Wednesday, June 5th, at 2.15 P.M.

The members will dine together at the Great Northern Hotel, at 5 P.M. Tickets, 6s. 6d. each.

Gentlemen intending to bring forward communications, or to join the dinner, are requested to communicate with the Secretary.

W. PROCTER, M.D., *Honorary Secretary*.

York, May 28th, 1878.

## BORDER COUNTIES BRANCH.

THE spring meeting of this Branch will be held at the Keswick Hotel, Keswick, on Friday, June 7th: President—Dr. LOCKIE; President-elect—Dr. GILCHRIST.

Gentlemen intending to read papers, or to be present at the dinner, are requested to give notice to the Secretaries.

R. MACLAREN, M.D., Carlisle, } *Honorary Secretaries*,  
JOHN SMITH, M.D., Dumfries, }

Carlisle, May 11th, 1878.

## THAMES VALLEY BRANCH.

THE next general meeting will be held on June 13th, at the Greyhound Hotel, Richmond, at Six o'clock.

Papers will be read by—

1. Mr. Balmanno Squire: The Use of Chrysophanic Acid.

2. Dr. Troncker.

3. Dr. Atkinson: Vaccination and Revaccination.

Dinner at the above hotel at Seven o'clock. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Honorary Secretary*.

Kingston-on-Thames, May 13th, 1878.

## EAST ANGLIAN BRANCH.

THE annual meeting of the above Branch will be held in the Infirmary, Peterborough, on Friday, June 21st, at 11.30 A.M., in conjunction with the Cambridge and Huntingdon and South Midland Branches: THOMAS J. WALKER, M.D., President elect, in the Chair.

After Branch preliminary business at 11.30, there will be a general meeting about 12.15, when the President-elect will read an address; at the conclusion of which, he kindly invites members to luncheon at his house before the next general meeting at 2.15 P.M., for papers, discussions, etc.

Gentlemen wishing to read papers, or to dine, are requested to communicate as early as possible with one of the Honorary Secretaries.

WM. A. ELLISTON, M.D., Ipswich, } *Honorary Secretaries*,  
J. B. PITT, M.D., Norwich, }

Norwich, May 14th, 1878.

## MIDLAND BRANCH.

THE annual meeting of this Branch will be held at Lincoln, on Thursday, June 27th: President—C. H. MARRIOTT, M.D.; President-elect, A. MERCER ADAM, M.D.

Members desirous of reading papers are requested to communicate with C. HARRISON, M.D., *Honorary Secretary*.

Lincoln, May 14th, 1878.

## SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.

THE annual meeting was held in the Library of the County Hospital, Canterbury, on May 16th, at 1.30 P.M.: present, P. B. HALLOWES, Esq. (Canterbury), in the Chair, and twenty-one members.

The minutes of the last annual and quarterly meetings were read and confirmed. The annual accounts were audited and passed.

*Secretary*.—Mr. W. Knight Treves, the Honorary Secretary, was re-elected for the ensuing year.

*The Chairman*.—It was proposed and carried unanimously, "That the custom hitherto holding, that the President of the East Kent and Canterbury Medical Society be the Chairman of the Canterbury meetings, be for the future waived".

*Ethical Committee*.—The members of the Ethical Committee were unanimously re-elected.

*The Dental Practitioners' Bill*.—It was decided that a petition against the Dental Practitioners' Bill should be laid on the table, to be signed by those members who had not already done so.

*The Places of Meeting* for the ensuing year were fixed for: Hythe, September; Canterbury, November 1878 and May 1879; Ashford, March 1879. Mr. John Hackney was elected Chairman of the Hythe meeting.

The members after the meeting paid a visit to the County Asylum at Chartham, and were much pleased with the extent and completeness of the asylum and the general arrangements for the comfort and welfare of the inmates.

## REPORTS OF SOCIETIES.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 10TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Ringworm complicated by Chloasma*.—Mr. MALCOLM MORRIS showed this case, which he considered to be unique. The patient was a young woman employed in a laundry, who perspired freely while at work. She had never worn flannel next to her skin. Eighteen months previously, she was nursing a child suffering from ringworm, and at that time noticed a small red spot on the back of the neck, which gradually spread from the edge, leaving healthy skin in the centre. After this, several other spots of similar character appeared, and spread in the same way. Last January, she observed on her chest a brown spot, which also spread. Her skin exhibited well-marked rings of tinea circinata situated on the neck and shoulders, also on the arms. On the chest and back were large patches of tinea versicolor. These patches not only occupied the greater part of these regions, but had spread within the circles of the ringworm; so that, as the ringworm fungus retired, the chloasma advanced. At the time of the meeting, the patient had been for some days using a strong lotion of hyposulphite of soda, but there was still a considerable quantity of the chloasma to be seen. Under the microscopes on the table, were specimens of the two varieties of fungus, kindly mounted for Mr. Morris by Dr. Sangster. It was well-known that both favus and ringworm could exist on the same skin, or, at all events, that one could produce the other. Mr. Hutchinson had also stated that ringworm in a child could produce chloasma in an adult. The chief point of interest in this case was the fact that the parasite of pityriasis versicolor could grow where the trichophyton could not exist.

*A Case of Yellow Fever*.—Mr. LEGGATT read notes of this case. The patient, a gentleman aged 52, single, before 1865 had been some years in India (Bengal) without any serious illness. He had always lived well, drinking a bottle of wine daily, and for the last four winters had gone to a warm climate on account of hæmoptysis and a delicate lung; returned from a sanitary voyage to and from Buenos Ayres, on March 17th, and arrived in London on the 18th. He had felt "seedy and bilious" twice on the voyage home, and after landing. He appeared well on the 19th, when he was seen by Mr. Leggatt. His appetite was not so good as usual; urine (night and morning) 1003, acid, almost colourless, no albumen. On the night of March 21st, he was seized with shivering and frequent vomiting after a good dinner. On the 22nd, he was languid and had headache, pain in the back, and loathing of food. He was hot. His pulse was over 100; the tongue white; bowels not moved. He took effervescent citrate of potash and soda, and his usual "tamar" at bedtime; and had milk and soda-water and tea. On the second day (22nd), he was freely purged, and had frequent vomiting, six ounces of black coffee-ground vomit. Pulse 108; temperature at noon 101.3 deg. Fahr. He was very depressed and languid, and asked if he had yellow fever. There were frequent motions during the day of pale whey-like liquid, with shreddy mucus. Evening temperature 100 deg. Fahr.; pulse 94; tongue moist, coated in the centre with a light drab fur, red at edges and tip. On the third day (24th), he passed a sleepless night. There were frequent motions of the same character. He vomited once, and was very depressed and weak. The face and conjunctivæ were yellow. No urine was passed, or possibly a little with the motions. Pulse only 48, weak and irregular; temperature 98.6 deg. Fahr. Great tenderness and pain existed in the epigastrium and right hypogastrium. At night, the pulse was 60, more regular. Frequent motions were passed. A grain of calomel was given at noon; eight minims of laudanum in an enema at bedtime; a teaspoonful of brandy every three hours during the day. Fourth day (25th). The patient slept a good deal. Two drab pultaceous foetid motions and about three drachms of urine were passed. The latter was of sulphur-

yellow colour, clear, neutral, and contained one-third of albumen. The yellowness of the skin had spread to the trunk and limbs and was deeper. The abdominal pain was increased. There was no sickness in the night. The pulse was 60, of fair power; temperature 98.3 deg. Fahr. Dr. Hawksley also saw the patient. Two grains of calomel and one grain of opium were given at 3 P.M., a water compress was applied to the abdomen, and a wide belt of impermeable piline around the trunk. Six hours after the opium, the patient was bright and free from pain. He took but little nourishment and no stimulants. In the evening, the temperature was 98.2 deg. Fahr.; two pale fetid motions had passed. Fifth day (26th). There had been a sleepless night, with frequent vomiting of clearish liquid, with flakes like beef-tea grounds; one darker vomit contained blood. He was very weak and torpid, but irritable. The abdominal pain and tenderness were much relieved. There were distressing attacks of hiccough for three-quarters of an hour together. Two grains of calomel were given at 3 P.M. and half a minim of creosote at 4 P.M. Dr. Murchison also saw the patient in the evening. His manner was altered, and he was jocose. He still vomited frequently; once, dark flakes of blood. The lower lip was livid and swollen. The tongue remained as before, moist, and without sordes. Temperature 99 deg. Fahr. (axilla). There was still some tenderness. The area of liver dulness was rather smaller, if anything, than natural. No urine had passed for sixty hours, and there was no sign of any in the bladder. There was no motion. Five grains of calomel were given. The trunk was enveloped in piline, wet with infusion of digitalis, four times the official strength. Sixth day (27th). The patient had a convulsion at midnight, followed by twenty minutes of unconsciousness, and four convulsions subsequently during the night. He vomited frequently. There had been saved eight ounces of clear liquid and four ounces of black coffee-ground vomit. The lower lip was black and swollen (ecchymosis?). The tongue was dry and brownish. There was the mercurial foetor. The pulse was 63, feeble, small; temperature 98 deg. Fahr. He had taken a little milk and barley-water. A drop of croton-oil was given at 2 P.M., and was followed by strong convulsion, in which the pulse was almost imperceptible. Dr. Murchison and Dr. Hawksley again saw the patient at 3.30 P.M. He was semicomatose, and did not recognise any one. A few purpuric spots were visible on the right instep and front of the right leg. The yellowness of the skin was darker. There had been no vomiting since the early morning, no motion, and no urine for seventy-nine hours. The digitalis was continued. A drop of croton-oil was given in the hope of relieving the uræmia by vomiting and purging. At 8.30, a severe convulsion left the patient comatose, and he died at 9.30. In this case, the temperature subsided on the third day from 101.3 deg. of the previous morning to the natural standard, above which it never again rose. There was great prostration on the morning of the third day, which passed away under very small doses of brandy (one ounce), and the pulse rallied from 48 to 60, and never afterwards fell below or rose above that frequency. The tongue continued moist to the end of the fifth day, and was free from sordes. On the sixth, it was brownish and dry. The mind was unaffected till the fifth day, when the patient became excited and a little unmanageable, but not at all violent. Blood was vomited on the second day, but not again till the fifth. There was never any blood in the motions. Death was evidently caused by uræmic poisoning, and it was not surprising that suppression of urine should occur in kidneys such as those described in the *post mortem* notes. The results of the necropsy, taken together with the symptoms above described and the fact of exposure to infection, satisfied all present that the illness was one of specific yellow fever. An epidemic of this disease existed at Rio de Janeiro when the steamer touched there on her outward and homeward voyages. First, on January 30th, three days after leaving, an officer of the vessel, assistant-purser, who had been ashore at Rio for one hour only, failed with the fever, and died at Buenos Ayres on February 12th. The vessel was in quarantine during her stay there. On the 14th, she left for Rio, and arrived on the 21st. During her stay, it was popularly stated that one hundred deaths a week were taking place from the epidemic. She left Rio on the 24th, and, two days afterwards, two more of the crew failed with the fever. One recovered; the other (the fifth engineer) died on March 5th, in latitude 8 deg. 13 min. N.; longitude 27 deg. 42 min. W. Neither of these patients had been ashore during the whole voyage out and home. The sick were isolated and disinfected freely used, and no one in attendance on the sick took the disease, nor did any other case occur on board. The subject of this paper landed on both occasions at Rio, and it appeared probable that in his case, as well as in the other three, the infection was contracted at Rio. If so, a period of incubation of twenty-five days resulted. It was possible, however, that, before reaching a temperature in which the poison was supposed to be inoperative (say, below 60 deg. Fahr., which would probably be in about

latitude 34 deg. 21 min. N., longitude 13 deg. 44 min. W., the position of the ship on March 12th, and which is about four degrees north of the isothermal line, which has a mean winter temperature of 58 deg. Fahr.), the infection might have been taken from the ship in which the three cases of fever had occurred. This would give an incubation of nine days. The ordinary term was said to be from one to fifteen days. But cases were on record which gave seventeen or eighteen days. The infective poison was generally supposed to be innocuous below a temperature of 60 deg. Fahr. But the experience of physicians in the Peruvian Andes showed that the fever could become epidemic and propagate itself at an elevation of fourteen thousand feet, and in a daily mean temperature of 48 deg. Fahr.; and it had been asserted by an American physician that the poison was not absolutely destroyed, but only rendered dormant, at any temperature above 32 deg. Fahr. If these facts were established, it would behave us in England to use great caution when any infected vessel reached an English port. It had happened already at Swansea, in 1855, that such a vessel did, in September, with a mean temperature for the month of 65 deg. Fahr. in the dock of that town, import the disease, which infected twenty-two persons and caused fifteen deaths amongst its population. In March last, the mean (maximum and minimum) temperature for the last eleven days was 38 deg. only. There were severe frosts at night, and north-west winds and some snow; one severe storm. This cold was preceded by warmer weather from the 18th to the 20th, when the thermometer was at 55 deg. or 53 deg. each day, and these days were preceded by colder weather, during which this patient entered the Channel and arrived at Southampton.

Dr. GREENFIELD read an account of the *post mortem* and microscopic examination of the case. The necropsy was made forty-three hours after death, the weather being very cold. The rigor mortis was well marked; yet there were signs of decomposition on the abdomen, the blood was fluid and contained gas-bubbles, and there was deep staining of the tissues around the veins. There was general intense icterus of somewhat brownish colour; ecchymosis in the lower lip. The liver—slightly enlarged, deeply jaundiced, and of light yellow colour—showed on section well-defined lobules, which were greenish in the centre; the surface of the organ was smooth, the capsule even, the gall-bladder and bile-ducts patent and healthy. The stomach contained much black fluid, resembling altered blood; its coats and those of the intestines were healthy. The spleen, free from disease, was small and firm. The kidneys, generally stained and somewhat decomposed, presented slight swelling of the cortex. The lungs contained numerous scattered hæmorrhages in the lower lobes, and subpleural ecchymoses. The pericardium was free from ecchymosis; the heart-wall was soft and greasy. Microscopic examination of the liver showed an interstitial exudation, part of which appeared to be oil, part recent, and of acute origin; the liver-cells were swollen, containing much pigment at the centre and periphery of the lobules, and some fat also at the periphery. Together with this were tracts of liver-tissue, in which the cells were swollen and split up into fragments, some containing nuclei, others bile-pigment or oil, and others apparently deliquescent; and between the cells were many nuclei. The kidneys showed changes exactly similar to those seen in the earlier stages of acute parenchymatous nephritis, and some older fibroid changes. The spleen was quite healthy. Dr. Greenfield remarked that the morbid appearances resembled in most respects those which had been described by many observers in the tropics; but that the changes in the liver, which were analogous in kind to, though less in degree than, those seen in acute yellow atrophy, established the existence of a true parenchymatous hepatitis in yellow fever—a condition which had been denied by some authorities. The alteration in the liver was, in fact, similar to that in the kidneys.

Dr. CAYLEY thought the symptoms of the case differed much from those of ordinary cases of yellow fever as given in text-books. The temperature was almost always normal. The symptoms were more like those of acute yellow atrophy; the patient had sickness and liver-symptoms, and died comatose.—Sergeon-Major HUTTON considered the poison of yellow fever quite distinct from that of malarial fever: the former was not a disease of swamps, but of towns. Parkes had thought the disease due to a fecal and not a malarial poison. It was consequently possible in these days of rapid intercommunication by steamboats that cases might be introduced to some seaport in Britain, whence, unless proper precautions were taken, the disease might spread far and wide.—Dr. GREENFIELD said that the fact that it might be a case of acute yellow atrophy was present to the minds of those engaged in the case. But was not the spleen usually enlarged in acute yellow atrophy? and were the changes in the heart and kidneys usual in that disease?—Dr. CAYLEY thought there were in the case some indications of previous disease of the heart and kidneys; then, again, the temperature almost

all the time was at or below the normal, which was not an usual circumstance in yellow fever.—Dr. GLOVER asked what were the previous labors of the patient.—Mr. LUGGATT, in reply, said that the temperature on the second day was 101.3 deg. at noon; the evening temperature being 100 deg.; and that it afterwards fell to normal, as was the case with yellow fever. Before death, Dr. Murchison had considered it to be a genuine case of yellow fever. The patient had formerly lived freely; lately, he had taken greater care of himself, and had travelled for his health's sake.

*Two Eruptions treated by the Ferrible and Deep Application of Lunar Cautery, together with Internal Remedies.*—Mr. SPENCER WATSON related notes of two cases. The disease in the first case—that of a policeman aged 28—attacked the eyebrow, eyelids, and root of the nose, and was attributed to the face having been injured by a kick. The treatment was at first by the internal administration of arsenic, and the local application of lunar caustic. Subsequently, iodide of iron, cod-liver oil, and iodide of potassium were given, and the caustic was repeated. Complete cicatrisation resulted, but after a prolonged course of treatment. There was no history of syphilis in this case. In the second case the cheek and ala of the nose were the parts attacked, the patient being a weakly man with a phthisical family taint and no history of syphilis. He, also, was at first treated by the internal administration of arsenic, but combined with iron and cod-liver oil. No improvement following, the lunar caustic was freely and deeply applied, and iodide of iron, cod-liver oil, and small doses of opium were given internally. Under this plan, a very rapid improvement took place, partly attributed by the author to an antiseptic dressing applied to the ulcerating surface.

The PRESIDENT thought the author was to be congratulated on the successful result of the treatment adopted in the case.

*Left Right Hemiplegia, with Double Optic Neuritis, and Obliteration of the Right Brachial Artery.*—Dr. BUZZARD related this case, which occurred in a girl aged 18, who was admitted into the National Hospital for the Paralyzed and Epileptic in December last. So slight were the symptoms of hemiplegia, and the girl's manner was so strange and confused, that at the first glance the case was thought to be one of hysteria; but the ophthalmoscope revealed both optic discs much swollen, with the veins very tortuous, and partly concealed by effusion. She was at once admitted; and, on further examination, it was found that pulsation in the right brachial artery ceased at the middle of the arm, the radial and ulnar arteries being both indistinguishable. It appeared that before admission she had had a fit, on recovery from which she had complained of loss of power in the arm and cutaneous anesthesia of the forearm. The anesthesia, which was marked on admission, disappeared in three days without treatment. She was then ordered iodide of potassium, and was subsequently injected hypodermically every day for twenty-nine days with Dr. Heubner's solution of peptone of mercury. She rapidly recovered the use of the arm, the optic neuritis gradually cleared away, and at the end of February she left the hospital. It was not until the patient had been six weeks under treatment that a sphygmographic tracing of the right radial pulse could be taken. This, which was shown to the Society, contrasted strongly with one obtained from the left radial artery on the same occasion. Subsequent tracings (which were also exhibited) showed the gradual return of circulation through the vessel. At the latter end of February, the girl had been examined by several members at a meeting of this Society, and the state of the radial pulse, which was still very imperfect, confirmed. In his remarks, Dr. Heubner pointed out that, although the case was obscured to a certain extent by some hysterical symptoms, the existence of optic neuritis must be looked upon, under the circumstances, as practically conclusive of the existence of disease in intracranial lesion, probably gummata or inflammation of the dura mater giving rise to the hemiplegia. The girl's history made it likely that the disease was of syphilitic origin. He pointed out the temporary obliteration of the brachial artery to chronic arteritis of syphilitic origin, of the kind which has been minutely described by Heubner as occurring in the arteries of the brain, and of which specimens were shown by the author and others at the late discussion of the Pathological Society upon visceral syphilis. If this were so, the case was, so far as he knew, the first one of thrombosis consequent upon this arterial change which had been noted during life in a vessel not belonging to the cerebral system. He had at first thought that when the girl fell in a fit the artery might have been injured and thrombosis thereby induced, but an investigation of the position and circumstances of her fall had, he thought, practically excluded this explanation.

The PRESIDENT, upon inquiry, learned from Dr. Buzzard that the heart was healthy.—Mr. BRIDENELL CARTER thought that at present one could not generalise concerning optic neuritis. Recently, he had

seen at St. George's Hospital a girl, also a prostitute, suffering from total loss of sight of the left eye, who was pallid and weak, but quite rational, and which he had pronounced to be a case of optic neuritis. He had treated her with a combination of iodide of potassium and bichloride of mercury, and in less than three weeks vision had quite cleared up, and the patient could read well. Her right eye had never been affected. Two days previous to that meeting, he had seen a surgeon who, four days before that, had suddenly lost vision of the right eye. He could only see large type with the concentric portion of the retina. The disc was then swollen, the vessels of the fundus obscured, and the ordinary appearances of optic neuritis were coming into view. The patient otherwise remained quite well. The artery at first was certainly not plugged; though the explanation of the symptoms was probably due to some arterial mischief. If the symptoms in Dr. Buzzard's case were due to syphilis, some other symptoms would probably arise.—Mr. G. BROWN inquired if the condition of the right radial artery in Dr. Buzzard's case had been noticed before the pulsation in it had ceased. Usually with plugging of an artery there were other signs, such as swelling, pain, and constitutional disturbance, which were here wanting. If it were a case of plugging, too, the improvement when it began would have gone on more rapidly. He thought it was possibly a case of abnormal distribution of arteries in the right forearm.—Dr. BUZZARD said that no pulsation could be detected in either the right radial or ulnar artery at the time of the patient's admission to the hospital; and a month afterwards he had failed to obtain a tracing. A week later, one was procured, whilst the second and third tracings subsequently drawn were so different as to show conclusively that there was no congenital malformation. There were no other symptoms than those of simple absence of the arterial pulsation when the patient had been examined at that Society on February 27th of this year. There were two reasons why the ocular symptoms were not due to embolic plugging. Firstly, he had never seen double optic neuritis so produced; and, even if that objection failed, the fact that it quite cleared up in two weeks showed conclusively that it was not due to embolism of the middle cerebral or other artery of the brain. Replying to the President, Dr. Buzzard said that the radial and ulnar arteries did not feel hard or cord-like.

## CORRESPONDENCE.

### THE MEDICAL ACT AMENDMENT BILL.

SIR,—Dr. Quain, in his speech to the Metropolitan Counties Branch, advises the profession to accept the amended Bill, on the ground that, as he expresses it, "half a loaf is better than no bread". The *Times*, in a leader, seconds this advice. I do not propose just now to discuss the wisdom of following such a course. But the speech and the leader proceed to enforce this concurrent view by a line of argument singularly fallacious.

Our proposition is, shortly: taxation and representation ought to go together. The Medical Council taxes us, and therefore we ought to be directly represented upon that body. The first part of this proposition is, in England, so unanswerable, that Dr. Quain and the *Times* are forced to dispute the second.

You are, say they, mistaken; the Council does not tax you; it is Parliament which has done so, and in Parliament you are directly represented. Parliament, we answer, has conceded to the Council the power to levy any tax it pleases up to £5. It has also imposed upon the Council certain obligations which it cannot fulfil without an expenditure of money. Suppose that these obligations require for their discharge a tax of £2 10s., the exaction of the other £2 10s. is discretionary with the Council; and, as they have always exacted £2 10s., to that extent the tax is directly imposed by them. Further than this, taxation implies two things: firstly, the power to raise money; secondly, the power to spend the money so raised. Now, there is no doubt that, whoever raises the tax, the Council spends it. In anticipation of this answer, we are told by the *Times* that, with regard to the money raised, "its expenditure is for purposes so obviously necessary, that the Council have scarcely any room for discretion in the matter". A great part of the amount raised is spent in paying the members of the Council for their attendance thereat, and I do not say that they are extravagantly rewarded. But this consideration affords really a still stronger plea for the reconstitution of the Council, than even the constitutional truism of taxation and representation.

Sir Dominic Corrigan candidly told the deputation of the Association Medical Reform Committee which interviewed the Medical Council that he himself represented, not the general interests of the profession, but those of the body which returned him. Ten members of the

Council voted the other day against the compulsory conjoint scheme; fourteen voted in favour of it. How does this proportion agree with general professional feeling? Four thousand nine hundred and ten medical men voted for it, and two hundred and sixty-four only against it. So we are paying ten gentlemen to oppose and obstruct a scheme which has such a preponderance of professional opinion in its favour. To my mind, this is even a stronger argument in favour of a reformed council than the taxation one. I should prefer a council appointed entirely by the Crown to one which, in my humble judgment, represents chiefly the trade interests of the corporations. Probably the worst that can be said against the Crown appointments is that, whereas we had originally two representatives of extra-metropolitan practitioners, we have now only one, and to-morrow may have none at all.

I still entertain the hope that so sagacious a minister as the Lord President may yet show himself wiser than some of his advisers, and may ensure the hearty and earnest co-operation of the great mass of the profession, and of our Association in particular, by granting us an instalment, if only a small one, of what we feel and assert to be our just rights. The principle of amalgamating corporations, and making one member represent two corporations, was established in 1858. Why not extend its operation, and so make room for a few direct representatives of the profession?—I am, sir, yours obediently,

Birmingham, May 28th, 1878. W. F. WADE, F.R.C.P.

#### THE REGIUS PROFESSOR'S WORK IN OXFORD.

SIR,—“Fine words butternò parsnips”; and if your editorial contributor, who “trusts that under Dr. Acland's guidance the medical school of Oxford may make some progress in its own special work”, can point to any progress achieved in the medical school, it would be more to the point. You and your correspondents have shown that, under his guidance, the medical school of Oxford has been crushed out of existence; that there exists nothing which can by any force of imagination be called a medical school at Oxford; that the funds left by former benefactors for medical teaching have been perverted to other uses; that Dr. Acland combines in himself a number of paid medical offices, which he has converted into sinecures; and that he not only does not fulfil the functions of his offices according to the intentions of the founders, but deliberately obstructs and prevents medical teaching, and has prevented the teaching of the essential branches of medical instruction.

Personal regard for the individual, however highly justified by his personal qualities and convictions, does not, in my opinion, justify the expression of any hope that public acts of this kind can be coupled with anticipations that the same official will promote in the future that which he has destroyed in the past, without since showing any evidence that he has repented.—I am, sir, yours,

May 28th, 1878. SPECTATOR.

#### THE RADCLIFFE INFIRMARY AS A CLINICAL SCHOOL.

SIR,—With the view of correcting the erroneous impression which must necessarily have arisen from the statements of your representative, as to the character and amount of work which is done in the surgical wards of the Radcliffe Infirmary, and to prevent the damaging effect which such a statement must have upon the support given to the institution by the public, I enclose a list of the operations, accidents, and other surgical cases now undergoing treatment in the Infirmary.

Operations for—1. Strangulated inguinal hernia; 2. Amputation of forearm; 3. Removal of epithelioma of lip; 4. Amputation of arm above elbow; 5. Amputation of leg below knee; 6. Partial amputation of foot; 7. Excision of eyeball; 8. Extraction of cataract; 9. Removal of large tumour from buttock; 10. Two fingers removed; 11. Tenotomy (talipes equinus); 12. Fistula in ano.

The accidents are—Fractured tibia and fibula (5); Fractured femur (4); Fractured fibula (1); Gunshot-wound of leg, from which a large piece of metal was removed; Wound of eyeball; Fracture of clavicle and concussion.

Other cases are—Tetanus following upon an injury to thumb; disease of elbow (for excision); phagedænic ulceration of penis and lip; one case of lumbar, and two of iliac, abscess; paracentesis thoracis; several cases of strumous ophthalmia and diseases of eye.

The other cases consist of the usual hospital cases of hip-disease, stricture, and cutaneous diseases, making in all sixty-seven surgical cases.

From the above list, which is by no means an unusual one, and which has about the usual percentage of operations, it will be seen

that the Radcliffe Infirmary can compare favourably with other hospitals containing the same number of beds in the amount of its surgical practice, and that the statement of your representative must have been made without due inquiry into the condition of the wards.—I remain, yours faithfully,

W. LEWIS MORGAN, L.R.C.P. Lond.,  
Radcliffe Infirmary, Oxford, May 28th, 1878. House-Surgeon.

#### CONSULTANTS AND ETIQUETTE.

SIR,—The experience of “A Consultant”, as given in his letter of the 11th, is what I have frequently to complain of. I started practice as a *pure* consultant, with every desire to consider the interests of the general practitioners with whom I am brought into contact. But they will not allow me to do so in many instances, nor at a cost which means an absolute sacrifice of my own interests. A patient comes to me, and I find, on inquiry, that he is attended by Mr. A. I write to Mr. A., and do not even get an acknowledgment of my letter, and the next thing I hear of the patient is that Mr. A. has sent him to Mr. B. in London.

A case in point has just occurred where the discourtesy has been even more marked. I wrote about the patient, and received no reply. I wrote again, asking if my first letter had been received; and no reply. What can we do with men who act in this way, but ignore them altogether? The patient is not the personal property of anybody whatever, and has a perfect right to consult whom he chooses. The consultant ought to regard the interests of the general practitioner who has been selected by the patient; but the general practitioner should equally regard the interests of the consultant who has been equally selected by the patient. There is a mutual distrust in this matter, which is much to be regretted, both in the interest of the profession and of the public; and, as long as it exists, *pure* consultants, as you understand them in your article on the subject, are quite impossible.—I am, etc.,

A BIRMINGHAM CONSULTANT.

SIR,—No doubt both opinions and experiences will differ as to the conduct of London consultants towards their medical brethren, more especially those in provincial practice. There are, undoubtedly, some consultants whose honour and courtesy are unquestionable; there are others (I write from experience) who will not scruple to annex a patient, even when sent specially to them by the usual medical attendant, and who will ignore, or contemptuously cast aside, the letter the patient takes to them. Complaints against some London consultants are more common, and do them more harm than they imagine; and provincial men often fight shy of sending patients to town, partly because of previous slights, but also because the conviction is gaining ground that, except in the case of a very few specialities practised by special men, the advantage is a very doubtful one, and that scientific medical education and experience are to be found in provincial towns in as high a degree as in the metropolis.—I remain, sir, yours faithfully,

A PROVINCIAL PRACTITIONER.

#### ISOLATION OF SMALL-POX CASES ON BOARD-SHIP.

SIR,—As every instance in which the scourge small-pox has been successfully grappled with by prompt and efficient isolation has some medical interest, I beg to put you in possession of the following facts. The ship *Hermione* left Calcutta on the 20th of December last, with four hundred and fifteen Coolie emigrants on board, for this island, and, when five days out, one of the emigrants presented himself to the medical superintendent with unmistakable symptoms of small-pox. Mr. St. Romaine at once conferred with Captain Roberts, the master of the ship, who proposed to turn one of the boats which was lashed to the side above the deck into a hospital, roof it with matting, and cover it with a tarpaulin. This was promptly done; and the patient was removed, and the whole ship fumigated and disinfected. Within the next few days, four other cases appeared, which were all removed to the boat, which was kept thoroughly fumigated and disinfected daily. No other cases appeared; these five all did well, and the last convalescent was discharged cured on January 14th. On March 10th, the *Hermione* landed here one of the finest and healthiest batches of emigrants that were ever brought to the West Indies. The infection was brought from the Coolie depot at Lucknow, where one of the women stated that her child had died of small-pox, ten or twelve days before she was sent away. Here we have in juxtaposition the results of carelessness and carelessness in dealing with such an enemy as small-pox; and, as we often read of the ravages of this disease among the Coolies on board-ship, the above simple means, which are always available, may prove of benefit in other instances similarly situated. I think it only due both

to Dr. St. Romaine and to Captain Roberts, that the success of their practical common sense should be placed on record.—I remain, sir, your obedient servant,  
A DISTRICT MEDICAL OFFICER.  
Grenada, West Indies, April.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### THE ROYSTON RURAL SANITARY AUTHORITY AND MR. BALDING.

WE have had the opportunity of seeing a copy of a correspondence that has taken place between Mr. Balding, the medical officer of the Royston Union, the Guardians of that Union, acting as the Rural Sanitary Authority, and the Local Government Board, to which we consider it desirable to direct attention.

It would appear that some months ago the Guardians, in their sanitary capacity, had a temporary building erected within the area of their workhouse grounds, but completely isolated from the workhouse itself, for the purpose of receiving cases of contagious disease occurring in persons above the pauper class. On the 26th of October last, one such case, that of a Miss Griffiths, was admitted, and Mr. Balding was requested to attend her and did so until the 21st of November last, when she was discharged. On her discharge, the Guardians preferred a claim of £4 0 5 against her for her maintenance; subsequently, this charge was reduced to £2 0 0, Miss Griffiths having shown that she was unable to pay a larger sum. "No charge was made, on this account, for medical attendance."

On the 2nd of January last, being the end of the quarter, Mr. Balding sent in an account for his professional attendance, medicines, etc., on this case, but the Board of Guardians repudiated his claim; whereupon, he applied to the Local Government Board to intervene in the matter. The latter body contented itself with forwarding his letter to the Royston Guardians, and asking for information. The Guardians, in their reply, admit the accuracy of Mr. Balding's complaint, but excuse themselves by stating that, "had the account been sent before the account with Miss Griffiths had been made out, a charge for medical attendance might have been included; but, inasmuch as Mr. Balding's claim was sent in subsequent to the settlement, the Authority felt that, while they had no power to pay it, they could not call on Miss Griffiths to pay the amount, having already given her a receipt in full for the account for her maintenance in hospital."

Anything more unfair than this proceeding of the Royston Board of Guardians can hardly be imagined. It was no part of Mr. Balding's duty, as workhouse medical officer, to attend a person admitted into a contagious hospital of the non-pauper class. That the Guardians considered that she was in a position to pay, was shown by their original demand of about £1 a week for her maintenance. Clearly, they had no right to ignore the attendance of Mr. Balding; and, although the Local Government Board has not expressed any opinion on the subject, there is no question, in our mind, that Mr. Balding could recover in the County Court from the Royston Board of Guardians a fair amount for his attendance on this case. At the same time, we would advise all rural medical officers, who may be likely to be called on in similar cases, to ascertain beforehand who is going to pay them for these extra services.

### THE YEovil BOARD OF GUARDIANS AND MR. GARLAND.

WE have seldom had occasion to draw attention to a more flagrant act of injustice than that which has been recently perpetrated by the Yeovil Board of Guardians, as reported in the *Western Press*.

It would appear that, in December last, a pauper named Cooper made application to Mr. Garland, District Medical Officer, for his advice. Mr. Garland examined him, and pronounced the opinion that he was incurable, as he was suffering from cancer of the lip, which had been operated on but had returned. Mr. Garland offered to send him to one of the London hospitals, but Cooper stated that he could not pay the fare. This Mr. Garland very generously offered to pay out of his own pocket, if the man could not raise the money in his native village. A few days afterwards, the man again called, and stated that he had got the money, whereupon Mr. Garland wrote to a friend in St. George's Hospital and obtained an order for his admission, and Cooper went to London. Nothing was directly heard from this man or from his family from that date; the only information Mr. Garland had was from a

former pupil, who wrote to state that the man's case was declared incurable. Subsequently, it would appear, he was discharged from the hospital, returned home, and some time afterwards died. After the man's death, the wife went to the police-station and asked where she could obtain a certificate; whilst there, she told the story above related, at the same time expressing her opinion that the going to London was the cause of his death, as he was unable to bear the fatigue of the journey. To the inquiry of the sergeant if Mr. Garland knew that deceased had returned from London, she said "I do not know; I suppose he must know of it." The sergeant said that he would see Mr. Garland; whereupon Mrs. Cooper rejoined, "He cannot give a certificate, as he has not seen my husband." The sergeant saw Mr. Garland, who promised to give a certificate, which he withdrew as soon as he had learnt that the woman was making complaint against him. Subsequently, the matter was brought before the Yeovil Board, and Mr. Garland was asked for an explanation. He attended the Board meeting on the 12th ult., together with Sergeant Holmes, and, having given their account of the case, the statement was considered satisfactory, and a minute to that effect was entered in the book; but at a subsequent meeting of the Board, the subject was again brought forward by the woman attending and making a direct complaint of neglect against Mr. Garland. Mr. Garland was again written to, and asked to attend their next meeting. This he very properly declined to do, alleging as his reason that he had attended once and had tendered his statement, and that it had been unanimously accepted as satisfactory; and that, if it were thought necessary to reopen the question, the matter should be inquired into by the Local Government Board. Thereupon, a long discussion ensued, some members objecting to a further review of the case, others insisting on it; ultimately, the woman was called in, when she asserted that Mr. Garland knew of her husband's return, and called a witness to depose to that effect; although, when at the police-office, she voluntarily stated that she did not know whether he had heard of her husband's return or not. Ultimately, the Board, by a majority of eleven to eight, many not voting, passed a censure on Mr. Garland for neglect of duty.

We are at a loss to determine in what respect Mr. Garland failed in his duty. Surely, if the woman wished for his attendance after her husband's return, it was incumbent on her to make a direct application, either through a fresh order or by a personal request. This, it is evident, she did not trouble herself to do.

We have gone into this case in some detail, as we feel that it is one that might happen to any district medical officer whose misfortune it might be to have eager antagonists on a board of guardians. We would advise Mr. Garland to make a direct application to the Local Government Board for an inquiry; thereby he will secure, not only an impartial investigation, but probably will be able to bring to light any influences which may have been brought into operation against him.

### DIPHTHERIA IN DENBIGH.

IN consequence of an outbreak of this disease, which attacked twenty-five persons and caused six deaths, Dr. Thorne Thorne was directed by the Local Government Board to investigate the conditions under which it occurred. He states that there can be no question as to the disease, as even the mild cases showed typical symptoms, including, in some instances, the limited paralysis characteristic of diphtheria. Dr. Thorne reported that the water-supply, except that from the water-works, was very bad; that the means of sewerage and drainage are defective in the extreme, as, except for a few street-lengths, the sewers are mainly old stone rubble drains, which allow stagnation and leakage of the sewage; and that many of the private drains are no better. It also appears that, although Dr. Lloyd Roberts, the late medical officer of health (who had resigned), had made himself acquainted with the sanitary condition of the district and reported to the Council, yet but little has been done to remedy the nuisances complained of. Reference is also made in the report to the fact that the results of a house-to-house inspection, made some time since, have not been entered in a book, so that the Council are ignorant of the sanitary condition of the district. As regards the inspector, it may be said as an excuse that he was only paid £15 a-year, which is quite insufficient for the requisite work. The medical officer of health is remunerated with what perhaps is considered the handsome yearly payment of £25, so that it is evident, as Dr. Lloyd Roberts made numerous inspections and compiled the requisite sanitary statistics for his district, he has not been overpaid for his work. The ideas of the Council as to payment is shown by a resolution adopted on Dr. Thorne's report, viz., that the inspector should devote his whole time to the work and be adequately remunerated, whereon it was agreed that the salary be £20 a-year, and an amendment, that it be £25, was rejected. This parsimony speaks ill for the proper carrying out of an

efficient system of drainage which has been proposed, or for the removal of the nuisances which caused this outbreak, as well as previous outbreaks of typhoid fever. The Council also agreed to arrange, if possible, with the Infirmary Committee to take their cases of infectious diseases, and postponed the consideration of the erection of a mortuary to the next meeting. It is to be hoped that the Local Government Board will not be satisfied with an apparent, but will require a substantial, compliance with the recommendations contained in Dr. Thorne's report.

## MEDICO-PARLIAMENTARY.

HOUSE OF LORDS—Friday, May 24th, 1878.

*Medical Act (1858) Amendment Bill.*—The Duke of RICHMOND and GORDON said that, in consequence of the amendments he found himself compelled to insert in this Bill, he should not ask their lordships to go into committee on the Bill that night, but to allow him to commit the Bill *pro forma*, that all his amendments might be reprinted, so as to enable their lordships to discuss them with greater convenience. When he introduced the Bill, he gave a considerable period of time between the second reading and going into committee, in order that, the Bill affecting as it did the public and the medical profession in a great degree, they might have ample time to consider its provisions, and that he might have the advantage of ascertaining the opinions of those interested in the subject, which might enable him to put the Bill in as satisfactory a state as possible. The medical profession readily responded to his request. He had received various deputations on the subject, and he had letters from medical men in all parts of the country. When asking for leave to bring in the Bill, he expressed his own opinion that there ought to be an uniform *minimum* standard of examination for those who sought to enter the medical profession; and he expressed his concurrence in the opinion that a conjoint examining board for each part of the United Kingdom was desirable. But there was a difficulty in the way of a conjoint scheme, which difficulty was raised chiefly by the Scotch Universities; and, consequently, at the time he did not see his way to introducing a clause rendering a conjoint board compulsory. But the representations which from time to time had been made to him, both before and after the second reading, made it clear that a conjoint scheme would be very advisable; and, in an endeavour to promote it, he ventured on what he thought might be an acceptable compromise. He suggested that it should be made compulsory on all the medical corporations of the country to form a conjoint scheme, leaving it to the various universities to come in if they thought fit. He had had his proposed compromise circulated through the country, and in answer to it he had had representations from various bodies. The medical corporations in England condemned his proposal, on the ground that nothing short of a conjoint board, to include the universities, would be satisfactory. The English Universities took the same view; the representations from Ireland were to the same effect; and from various medical societies in the metropolis, who treated the question in a very impartial manner, he had received representations in the same direction. He was bound to say that the opinion of those various bodies and societies was opposed to this compromise, and he would not be dealing honestly with the House if he did not say that he could not resist the arguments they had brought under his consideration. Desiring to put the Bill into a shape in which it would be of real advantage to the medical profession and satisfactory to the whole country, he had come to the conclusion that he must ask their lordships to allow him to amend it, so as to make a conjoint board for each of the three portions of the United Kingdom compulsory. The chief opposition to such a proposal came from the Universities of Scotland, but he hoped that his endeavours in the way of compromise would show that he had, as far as possible, deferred to their views. He hoped the Universities of Scotland would appreciate his motives, and see that he was doing what he believed would be best for the medical profession and the public generally. With this explanation, he would ask their lordships to go into committee *pro forma*. He proposed that the discussion in committee should not be taken till the week after Whitsuntide week.—VISCOUNT POWERSCOURT begged to congratulate the noble duke on his proposal to make a conjoint scheme compulsory.—The Marquis of RIXON believed that the course proposed by his noble friend was most desirable in the interest of the public; and he hoped that the Universities of Scotland would, in the interest of the public, withdraw their opposition to it. But, however that might be, he felt convinced that his noble friend had adopted the right course.—EARL GRANVILLE also congratulated the Lord President. Having accompanied a deputation from the University of London, he could bear testimony to the patient

attention with which the noble duke listened to the representations made to him by that deputation. He believed that change proposed in the Bill would prove of great advantage to the public and the medical profession.—The Bill then passed through committee *pro forma*.

HOUSE OF COMMONS.—Wednesday, May 22nd, 1878.

*Contagious Diseases Act Repeal Bill.*—Sir H. JOHNSTONE moved the second reading of the Bill, submitting that the returns which had been laid before Parliament afforded a convincing proof that the continuance of the Act was not justified by the circumstances of the case. The hon. member was entering into a variety of details in illustration of his argument, when Mr. MOORE moved that the ladies' gallery be cleared. This was put to the House and lost.—Sir H. JOHNSTONE resumed his speech, remarking that, on the part of many of the towns of this kingdom, which protested against these Acts, he was bound to say that the very construction of them was a direct interference with the powers and privileges of municipal authorities. The idea of making policemen the special guardians of public morality was in itself so absurd, that he would not waste time in dwelling on that topic. If there were one woman who made great personal sacrifices for the good of the soldiers of England, that woman was Florence Nightingale, and she had been the first to sign the petition he had presented that day, feeling sure that a system of Government regulation and examination was contrary, not only to the rights of women, but to the general liberty of the state. He was convinced that year after year would bring conviction to the minds of those still undecided, that it was impossible to maintain these Acts in the face of the public feeling of the country, which, whether rightly or wrongly, was persuaded that they had not done any great amount of good, while they had outraged the public feeling of this country to a most terrible extent.—Mr. W. H. SMITH expressed his great regret that the hon. baronet should have thought it necessary to bring this most painful question before the House. He was very far from calling in question the motives of the hon. baronet, and of those who took an interest in the subject, but he could not help feeling that they took but a very partial view of it, and one which it was not unnatural men should take who were not able themselves carefully and thoroughly to study it. From experience and examination, he had come to the conclusion that these Acts were beneficial to the public morality, to the persons who were principally affected by them, and to the state.—It was now a quarter to six o'clock, and the debate, in accordance with the standing order of the House, was adjourned.

Friday, May 24th.

*The Rev. Mr. Dodwell.*—Dr. KENEALY asked the Secretary for the Home Department whether he would explain to the House the grounds on which he refused to release the Rev. Mr. Dodwell, who had been reported to him, on high medical authority, as being of perfectly sound mind.—Mr. CROSS said Mr. Dodwell, after the verdict given in his case, had been sent in the ordinary course to Broadmoor. Some time ago, letters were received at the Home Office from Dr. Winn and Dr. Forbes Winslow as to his state. Those letters were sent on April 15th to the authorities of Broadmoor, with an intimation that when they were able to report that it would be consistent with the safety, both of the public and the prisoner himself, that he should be either absolutely or conditionally discharged, his case would be considered, and not till then. No report had yet been received.

Monday, May 27th, 1878.

*Post Mortem Examinations on Lunatics.*—Mr. F. TAYLOR asked the Secretary of State for the Home Department whether he would take into consideration the expediency of issuing some authoritative memorandum indicating the conditions upon which examinations upon the bodies of persons dying in lunatic asylums should be permitted or enforced.—Mr. CROSS said he had been in communication with the Lunatic Commissioners on the subject, and they had informed him that their opinion with respect to it was very strongly expressed in a report which they had presented in 1870, and also in evidence which had been given last year. If, after looking at that report and the evidence, the honourable gentleman wished to put any further questions, he should be happy to make additional inquiries.

*VOLUNTEER SURGEONS.*—The following Volunteer Surgeons, having undergone the requisite examination, have been granted certificates of proficiency, entitling their respective corps to an additional government grant:—Surgeon George Bland, 5th Battalion Cheshire Rifle Volunteers; and Acting Surgeons Thomas Shaw, 27th Cheshire R.V., W. R. Davies, 16th Cheshire R.V., and John Somerville, 8th Cheshire R.V.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on May 23rd.

Andrews, William S., Dover (University College)  
Aphorpe, Frederick W., Lee, Kent (Guy's Hospital)  
Bislee, Alfred J., Hulton, Somersetshire (St. Mary's Hospital)  
Buckle, John, Catton, Norwich (St. Bartholomew's Hospital)  
Euler, George W., Appleton, Abingdon (Guy's Hospital)  
Candler, William J., Harleston, Norfolk (St. Bartholomew's Hospital)  
Clark, James R. A., Cavendish Square (University College)  
Clitherow, Robert E., Horncastle, Lincolnshire (King's College)  
Crouch, Edward T., Devonport (Guy's Hospital)  
Edwardes, William W., Llanantffraid, Montgomeryshire (St. Mary's Hospital)  
Fulton, James, St. Thomas's, Canada (St. Thomas's Hospital)  
Good, Frederick T., Highbury Hill (St. Bartholomew's Hospital)  
Hawkins, Howard, Lee, Kent (Guy's Hospital)  
Jackson, Thomas, Great Torrington, Devon (Middlesex Hospital)  
Ling, Maurice E., Saxmundham, Suffolk (London Hospital)  
Shaw, George, Blackheath Park (Westminster Hospital)  
Smith, Kenneth R., Stamford Hill (University College)  
Snowden, George H., Ramsgate (St. Mary's Hospital)

Five candidates were rejected.

The following members, having undergone the primary examination for the Fellowship at the half-yearly meeting of the Board of Examiners on May 27th, will be admitted to the pass examination when qualified.

Messrs. Edward Forster Brockman, L.R.C.P.Lond., diploma of Membership dated November 14th, 1866, of St. George's Hospital; Charles Henry Newby, January 22nd, 1873, of St. Thomas's Hospital; Robert William Greenish, May 27th, 1875, and Samuel Herbert Burton, January 28th, 1876, both of University College; George Andrew, January 21st, 1877, of St. Bartholomew's Hospital; Richard Shalders Miller, August 1st, 1877, of University College; and Albert William Denis Leahy (not a Member), of the Charing Cross Hospital.

Thirteen candidates were rejected.

The following gentlemen passed on May 28th.

Messrs. William R. Williams, diploma of Membership dated April 24th, 1877, of University College and Middlesex Hospital; Charles Atkin, Sheffield and Guy's Hospital; Robert J. Williamson, St. Thomas's Hospital; Cecil L. S. Branson, St. George's Hospital; John Whitehouse, Birmingham; Denis McDonnell, King's College; Richard Bordin, Liverpool School; Thomas D. Savill, St. Thomas's Hospital; Anthony A. Bowley, St. Bartholomew's Hospital; Reginald Pratt, University College; Frederick C. Fisher, St. George's Hospital; Henry T. Bassett, Guy's and Birmingham; William J. Penny, King's College; David A. King, St. Bartholomew's Hospital; John Phillips, King's College and Cambridge; Thomas Kirsopp, St. Bartholomew's Hospital; and John F. W. Silk, King's College.

Eight candidates were rejected.

The following gentlemen passed on May 29th.

Messrs. Percy E. Shearman, Charles J. Bond, Victor A. H. Horsley, of University College; Francis Howe and John K. Dodd, St. Bartholomew's Hospital; James T. Brett, Guy's Hospital; Henry E. Garrett, Charing Cross Hospital; and Edwin H. Greves, of the Edinburgh School.

Thirty-six candidates out of the sixty-eight examined, having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their anatomical and physiological studies for six months.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 23rd, 1878.

Hare, Evan Herring, Putney  
Jacob, Henry Garrard, Southsea  
Moorhouse, Edward Dobson, Manchester

## MEDICAL VACANCIES.

THE following vacancies are announced:—

**HULLERSFIELD INFIRMARY.**—House-Surgeon. Salary, £25 for first year, with board and residence. Junior House-Surgeon. Salary, £15 per annum, with board and residence. Applications to be made on or before the 5th instant.

**KENT AND CANTERBURY HOSPITAL.**—Physician. Applications to be made on or before the 28th instant.

**LIMERICK UNION.**—Resident Medical Officer, at a salary of £200 a year, without rations. One Resident Apothecary, a Pharmaceutical Chemist, at £100 yearly, without rations. Furnished apartments in both cases. Applications to the 31st instant.

**LONDON LIVER HOSPITAL.**—Resident Medical Officer. Salary, £200 per annum, with residence, coal, gas, and attendance.

**SOMERSET COUNTY LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £120 per annum, with board, residence, and washing.

**TRALEE UNION.**—Bosna Dispensary District. Medical Officer for No. 1 Division of the District. Salary, £50 per annum, £10 as Sanitary Officer, with the usual Registration and Vaccination Fees. Personal attendance of candidates necessary on the day of election; viz., the 5th instant.

**WEST BROMWICH DISTRICT HOSPITAL.**—House-Surgeon. Salary, £ per annum, with board, residence, and washing. Applications to be made or before the 26th instant.

**WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.**—House-Physician. Salary, £100 per annum, with board, washing, and apartments. House-Surgeon. Salary, £100 per annum, with board, washing, and apartments. Applications to be made on or before the 24th instant.

**YORK FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.**—Assistant Medical Officer, from 25 to 35 years of age. Salary, £150 per annum, with fees. Applications to be made on or before June 4th.

## MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

HOGGAN, George, M.B., elected Medical Officer of St. John's Hospital for Diseases of the Skin.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

### BIRTH.

DUFFEY.—On May 23rd, at 30, Fitzwilliam Place, Dublin, the wife of George F. Duffey, M.D., of a daughter.

### MARRIAGE.

SMITH—FREER.—On May 23rd, at Oldswinford Church, Stourbridge, by the Rev. R. H. Streeten and the Rev. H. Sherrard, Henry Hammond Smith, late Madras Medical Service, youngest son of the late C. J. Smith, Inspector-General of Hospitals, Madras, to Ethel, youngest daughter of R. L. Freer, Esq., Stourbridge.

**BEQUESTS, ETC.**—Miss Pringle has bequeathed £300 to the Hospital for Incurables, Donnybrook; £300 to the Deaf and Dumb Institution, Claremont; and £300 to the Cripples' Home, Bray.—"In Memoriam" has given £50 to the Hospital for Incurables, near Dublin.

DR. GEORGE BENNETT, F.R.S., to whom the honorary gold medal of the Royal College of Surgeons was awarded in 1834, was, on a recent visit to Rome, elected an Honorary Member of the Italian Geographical Society.

**ROYAL COLLEGE OF SURGEONS: PASS EXAMINATIONS.**—The following analysis of the last examination for the diploma of membership of the Royal College of Surgeons may, perhaps, be interesting. There were eighty-three candidates examined. Those already in possession of recognised medical licences, and therefore not examined in medicine, are represented as follows: "L.S.A.", twenty-two; "L.R.C.P.Ed.", three; "L.R.C.P.Lond.", one; "L.R.C.P.Edin. and L.S.A.", one; "L.K. & Q.C.P.I.", one; "M.D. Queen's Coll., Canada", one; "M.D. Toronto and L.R.C.P.Ed.", one; "M.D. Toronto", one; and "M.D. New York", one. Of the eighty-three candidates, fifty-four received their diplomas; thirteen were approved in surgery, and, when qualified in medicine, will be admitted members of the College; eight were rejected in medicine, and five were approved; five were referred in surgery, and ten altogether rejected.

**ILLEGAL EXPOSURE OF A SMALL-POX PATIENT.**—Mary Whelan, of Queen Street, East Greenwich, appeared at the Greenwich Police-court on Wednesday to a summons, at the instance of the Greenwich District Board of Works, charged with exposing her daughter, suffering from small-pox, in a public thoroughfare. Mr. Spencer attended in support of the prosecution; and Thomas Conden, an inspector in the service of the Board, gave evidence showing that the defendant, on the 25th of March last, took her daughter, a servant to a family residing in Tollington Road, Islington, and rode with her in an omnibus to London Bridge, and thence in a railway-carriage to Greenwich; they then walked along a distance of a quarter of a mile to the defendant's home. A fine of ten shillings was imposed, and two shillings cost of summons.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY.**—The eighth and last meeting of the twenty-second session was held at the Royal Kent Dispensary, Greenwich Road, on Friday, May 3rd: W. Johnson Smith (President) in the chair. Drs. Gooding and Moon, and Mr. Lockhart, were appointed auditors of the treasurer's account. Dr. John Curnow of King's College was unanimously elected an honorary member. The following members brought forward cases for discussion: Dr. R. Gooding, Cases of Pregnancy complicated with Small-Pox; Dr. Creed, A Case of Intracardiac Thrombosis (Recovery); Mr. C. P. Creed, A Case of Compound Comminuted Fracture of the Skull in a Boy aged 9, followed by a very large Hernia Cerebri (recovery; boy shown in good health). The annual dinner is fixed for Tuesday, June 25th, at the "Ship", Greenwich, at 6 for 6.30 P.M. precisely. Tickets 15s., inclusive of wine and coffee.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**WEDNESDAY.**—Obstetrical Society of London, 8 P.M. Specimens: Extra-uterine Fœtation, by Dr. Hayes; Hand-behind-Head Presentation, by Dr. Bryden; Drawings of a living Double Monster, by Dr. Wiltshire. Papers: Dr. Aveling, "The Curves of the Forceps: their Origin and Use"; Dr. Matthews Duncan, "The Revolutions of the Fœtal Head in passing through a Brim contracted in the Conjugate Diameter";—Royal Microscopical Society, 8 P.M. Mr. F. A. Bedwell, "On the Framework of the Mustax of *Meliceria Rigens*"; The Rev. W. H. Dollinger, "On the Measurement of the Diameter of the Flagella of Bacterium Termo".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL**, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the **JOURNAL**, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**ERRATUM.**—In the **JOURNAL** for May 18th, page 724, column ii, third line from bottom, for 1824 read 1835.

## VACCINATION.

**SIR.**—With your permission, I desire to lay the following facts before your readers. Every one in the profession knows more or less of the difficulties that are to be contended with in reference to vaccination; and without at all despising the very fine feelings displayed by the mothers of the rising generation, where every one considers her own child purer and brighter than her neighbour's, I think that that feeling is very much abused amongst a certain class of people who do not understand logic, and into whose heads logic cannot be driven. Within the last two or three years, my attention has been called to the subject of vaccination by its being in a few cases followed by a rash or erysipelas; and in many of these cases I have known the parents to be syphilitic, and when vaccinating their children have expected the result that in many cases followed the operation. The following case will put the subject prominently before your readers.

About four years ago, I attended a gentleman for syphilis, who was lately married. When his young wife found herself in that condition which foretold her that she should require the service of some one, I, being her mother's family attendant, was engaged to attend her, although not without some objection on the part of the husband. The child, on being born, had no appearance of syphilis, or any disease whatever, and continued in perfect health up till the time of vaccination; but my suspicions being aroused, I was most particular in subjecting the child to that operation, and selected a very healthy child, to whom I particularly called the mother's attention. I vaccinated three from the one arm, two of which did extremely well, the arms healing in the ordinary course, without the least trouble; the other, as I suspected, came out all over with what appeared to be a syphilitic rash, which got me into not a little trouble; and it was only by my sending for the husband and using to him pretty strong antisyphilitic logic, that it did not become a very fine case for the antivaccinators. I shall be glad to hear of any similar case.—Yours truly,

DAVID ALEXANDER.

Clydesdale House, Hull, May 25th, 1878.

**CORRESPONDENTS** are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

**THE** following were the questions on Surgical Anatomy, and the Principles and Practice of Surgery, submitted to the candidates at the pass-examination on May 17th, when they were required to answer at least four, including one of the first two, out of the six questions. 1. Describe the origin, course, and relations of the internal pudic artery; and state in what accidents or operations this vessel or its branches may be wounded. 2. Describe "Chopart's amputation" through the foot; and name the structures in their relative positions which are divided in performing that operation. 3. Under what circumstances may iritis occur? Describe the characteristics of this disease in the acute form, and its appropriate treatment. 4. How do you distinguish between an adenoma and a scirrhous of the female breast, before and after removal by operation? 5. Describe the operations which may be adopted for paracentesis thoracis: what are the precautions to be taken in performing them? 6. Describe the signs of a dislocation of both bones of the forearm backwards at the elbow-joint. For what injuries may this accident be mistaken? and how would you reduce and subsequently treat this dislocation?

On the following day, May 18th, those candidates who had not undergone any previous examination in medicine, or did not possess of a recognised medical licence, were required to write answers to the following questions on the Principles and Practice of Medicine. 1. Discuss the pathology, symptoms, treatment, and condition of the urine in hæmaturia, omitting the subject of hæmorrhage from surgical injuries. 2. Describe the morbid anatomy, symptoms, and results of enteric fever. 3. What medicinal plants belong to the order Euphorbiaceæ? Give their medicinal properties and uses, and the names and doses of their several pharmacopœial preparations. Write an unabbreviated prescription in Latin, with directions for use, for a case of acute bronchitis.

The following questions on Anatomy and Physiology were submitted to the candidates at the primary examination for the Fellowship on May 24th, when they were required to answer all of them. 1. State the velocity of the blood in the several parts of its course, and describe the methods by which this has been ascertained. 2. What are the essential structures of a secreting organ? Describe the several types of secreting glands. Give evidence of the direct influence of the nervous system upon secretion. Describe the poison-apparatus in ophidia. 3. Describe the course and relations of the profunda cervicis artery, and the dissection required to expose it. 4. Describe the dissection required to expose the course and distribution of the obturator nerve.

## MEDICAL USES OF THE TELEPHONE.

**SIR.**—As you have mentioned the experiments in progress in America, and as I believe I am the first to have suggested and experimented on the application of the electric telephone to auscultation in this country (my observations having commenced on the 1st of January), I thought it might interest some of your readers and open the way to further suggestions, if I brought before them the actual results up to the present time, and the difficulties in the way of their further development. The telephone I have generally used is one which I put together myself, and which I have proved to be very accurate in conveying the sounds of the voice, reading, speaking, whistling, singing, and blowing; a tune played on a violin at the opposite corner of a small room could also be heard through it, the hearing telephone being in a distant part of the house. I subsequently made a further improvement on this by removing the wood mouth piece, and screwing on in its place a deal stethoscope. The result of my observations in my own practice, in my family, and on some patients I examined at the Brompton Hospital for Consumption, through the kindness of Dr. Tatham, is as follows.

1. On applying the telephone to the chest of a healthy person, no sounds, whether of breathing, voice, or cough, are communicated. The same is the case with regard to the normal sounds of the heart.

2. When the telephone is applied to a very loud cardiac murmur, a sound may sometimes be heard, not continuous, but intermittent, and not distinct enough to be accurately defined.

3. When applied to the trachea of a healthy subject, the voice-sounds may be heard, and also the breathing, when made preternaturally loud by voluntary effort. In a person recovering from catarrh, the voice may be heard distinctly in this manner (i.e., from the trachea), and also the cough, following which may be recognised a large rhonchus.

4. A cough directed into the telephone could of course be heard distinctly; it is divested of all extraneous sounds, and heard merely as a sharp metallic click. The gentlest breath directed into my telephone may also be heard perfectly.

At present, it is difficult to see that much advantage can be derived from the application of the telephone to diagnosis, owing to the fact that apparently no sound can be heard through it which is not heard equally well, or better, with the stethoscope. It is, however, possible that some sounds that interfere with diagnosis may be separated from those that are material to it. I am speaking now of the telephone in the present state of its development. I believe an improvement in its constitution is now being carried out, by which all sound is conveyed by it will be greatly intensified. If this be the case, it may almost supersede the stethoscope.—Yours truly,

J. FOSTER PALMER.

120, King's Road, S.W., May 20th, 1878.

## UNQUALIFIED ASSISTANTS.

**SIR.**—I am sure many unqualified assistants will thank "Undergraduate" for his letter detailing his uphill work for a diploma, and you for your kindness in giving space to it in your valuable **JOURNAL**. In speaking and writing so bitterly of unqualified assistants, few people look at the dark side of our life, or think of the struggles we have to maintain to enable us to pass the portals dividing us from our more fortunate qualified brethren. I am afraid the case of "Undergraduate" is a far from uncommon one. My own career up to the present has been somewhat similar. I, too, was articled to a surgeon for four years, and ere I left him to commence my career as an unqualified assistant, he had done his share towards initiating me into the mysteries of general practice. My own savings, backed by other help, enabled me to enter hospital; but I was compelled to continue my assistance, and I have been, and am, giving nine hours daily to my principal; nine hours more are taken up with lectures, study, and meals; the remaining six I devote to rest. When preparing for an examination, I cannot allow myself more than four or five hours for repose; but I hope in a few months to be placed among those who have won their laurels, and are in the magic circle of qualified men.

In speaking of unqualified assistants, I think the fact is lost sight of that many

men undertake the duties as the means to an end. Without the aid afforded to them by this means, they would be debarred from entering the medical profession, and many good men would be lost to it. Some may say, if your course be so hard, why do you not choose a less arduous one? Why should such impecunious individuals attempt to enter the profession? Is the goal worth striving after? May you not pay too dearly for your qualification? To these questions we can only answer, that we love the profession; we think it an honour to belong to it, and to become members of it we are content to suffer; we are willing to pay dearly. But while some of us attain the goal of our hopes, how many are there of whom the world knows nought, who, after years of struggling, leave the battle to the strong and the race to the swift, and commence a new path in life, too often, alas! irretrievably ruined in health? or some, again, which for them is perhaps better, die in harness as unqualified assistants; while others live only to grasp the prize, which they enjoy for a brief moment, when it is snatched from them for ever, and their footsteps in the sands of time are obliterated by those crowding after them.

If the struggles of some of us have to maintain were known, we should see less often the harsh remarks made on us, and those who now cry "Away with them!" would hold out to us the right hand of fellowship, and lighten our daily struggle by the kind voice of encouragement and sympathy.

I must apologise for trespassing so much on your valuable space; but I know from you we shall receive that which so few accord us—*justice*.

#### UTERINE HÆMORRHAGE.

SIR,—At the Glasgow Medico-Chirurgical Society's meeting of March 1st, 1878, I showed an instrument by which I could instantly arrest uterine hæmorrhage. The members at first thought (like Dr. Jay) that the invention was old; but before I had finished describing it, they were convinced of its originality and utility. There are two ways by which medical men endeavour to arrest uterine hæmorrhage. One is by trying to excite uterine contractions. For this purpose, some will give ergot, others turpentine, or one will inject hot water into the uterus, another cold. Mr. Sawyer's instrument (to which Dr. Jay referred) is a bag of India-rubber, with two tubes attached to it; cold water is poured in by one tube and escapes by the other before it has time to do me harm; in other words, it is an ingenious and simple way of injecting cold water into the uterus in order to make it contract. I think it requires no argument on my part to prove that any of these modes of treatment can only succeed where the hæmorrhage depends on inertia of the uterus, and that none of them can be relied on as an infallible remedy even for that. In cases of adherent placenta, it is impossible for them to have any beneficial effect. Another way is by the use of styptics, as recommended by Dr. Barnes; but I would ask, is this not going back to the barbarous times, when after amputation boiling pitch or stercoræ were employed to stop the hæmorrhage?

I will now endeavour to describe the instrument I have adopted, and what induced me to try it. In Churchill's *Midwifery*, the last sentence in the chapter on "Flooding" contains the following words: "Mr. Slyman proposes an elastic bag introduced into the uterus and filled with cold water or air, so as to make pressure." Nothing more is said about it, and probably there the matter ended. I thought the idea of arresting uterine hæmorrhage by pressure a good one, but in this case very imperfectly carried out. It was not stated how much pressure was required, nor was there any provision made for permitting the uterus to contract. In the *Encyclopædia Britannica*, I discovered that if a tube were inserted into an artery the action of the heart would raise the blood in it seven feet and a half; from this I knew that if a tube of that length were attached to an elastic bag in the uterus, and bag and tube filled with water, the uterus would then sustain a pressure equal to that which the heart is capable of exerting, and hæmorrhage would be impossible. If the uterus contracted, the water would be expelled through the tube; but after contracting, if it relaxed (which it always does), the water would sink in the tube, and for every foot it sank there would be about one pound less pressure per inch on the uterus; and if the pressure in the bag were less than in the blood-vessels, hæmorrhage would set in again. Letting the end of the tube dip into a glass vessel remedied this defect. I cover the bag well with glycerine; it will prevent septicæmia, and hasten the separation of any dead portion of placenta. After the bag has been introduced, I use whatever pressure is necessary to arrest the hæmorrhage by injecting tepid water; then I separate the pump from the tube, and put the end of it (the tube) into the receiving vessel at the proper height (it can be suspended from the ceiling, or anything else convenient). Nature does all the rest.

I have now given the history of my invention, and believe no man can find fault with it, except through ignorance or prejudice.—I am, etc.,

DAVID CHRISTIE, L.F.P.S. Glasgow, L.R.C.P. Edin.

Carriage by Letterkenny, co. Donegal, May 2nd, 1878.

THE following communications have been handed to the General Manager:—Mr. B. Brooks, Hull; Mr. W. R. Davies, Sandbach; Mr. W. Ganderion, West Bromwich; Mr. G. H. MacSwiney, Liverpool; Messrs. Corby, Stacey, and Co., London.

#### INSURANCE OFFICES AND MEDICAL FEES.

SIR,—I forward to you a correspondence, which I hope you will think deserving of publication. The great majority of insurance offices deal fairly with the profession, and it is well that we should all know which of them do not so.—Yours truly,

Mortimer House, Clifton, May 13th, 1878. JOHN BRIDGER.

(Copy.) "Mortimer House, Clifton, May 14th, 1878.

"Sir, I have received from your office a request for a report on the health of Mr. X. Y. This request is not accompanied by the fee, or promise of a fee, which a physician expects from an insurance office. I should be glad to know whether the omission was accidental.—I am, very obediently, JOHN BRIDGER, M.D., etc. The Secretary London Life Association."

(Copy.) "London Life Association, 31, King William Street,

London, E.C. 4, May 13th, 1878.

"Dear Sir,—This being a mutual insurance society, and not a trading corporation, it requires every person applying to be admitted to its advantages to furnish evidence that he is in good health, without expense to the society. If he cannot do this, he cannot be admitted. Mr. X. Y., therefore, and not this society, made application to you for a report, and the form in which that might conveniently be given was supplied to him to save trouble. Your application for a fee should therefore be made to him.—I am, dear sir, your obedient servant, EDW. DOCKER, Secretary.—Dr. Beddoe, Mortimer House, Clifton."

(Copy.) "Mortimer House, Clifton, May 7th, 1878.

"Dear Sir,—The statement that the application was made to me by my patient, and not by your office, appears to me to be a subterfuge unworthy of the directors

• The application was on a printed form, and came from the office.

of a respectable corporation. The information is obviously required by, and for the advantage of, the association, to guard against the possible entrance of bad lives, and it is bound in honour to defray the expense of obtaining such information, instead of endeavouring to wheedle it out of physicians without payment. It is nothing to me that my patient, who is an honourable man, would certainly repay me; I proceed on the ground of principle. Your rule being what it is, I must decline further correspondence, and remain, yours faithfully, JOHN BRIDGER.—The Secretary London Life Association."

SIR,—Having examined a medical man for life-assurance, am I supposed to hand over the fee to him, or retain it myself?—I am, etc., J. E.

\* The fee being paid by the office, may evidently be retained by J. E. His service is to the office, which has no claim upon him for gratuitous work.

ENQUIRER.—It is not a duty of the clerks to guardians to send the names of successful candidates for appointments; nor are they sent by the Local Government Board. For the information on this subject which is communicated to our readers, we are indebted to the courtesy of the clerks to the boards of guardians and to other correspondents.

#### SUPERINTENDENTS OF ASYLUMS.

F.R.S.—The appointments of medical superintendents of the county and borough asylums of Great Britain rest with the Committees of Visitors, and are almost invariably filled from those who have had experience in lunacy practice as assistant medical officers; but those in Ireland are made by the Government. The duties, besides medical, are a general control and supervision under, combined with responsibility to, the Visiting Committee, with whom it is optional to grant a retiring pension, not exceeding two-thirds of the salary and allowances, on account of age, ill health, or long service; provided always such is sanctioned by the Court of Quarter Sessions or by the Town Council, the grant in the latter case being paid out of the local fund. For further information on this latter head, see Lunacy Acts, 16 and 17 Vict. c. 27, s. 57.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fifeshire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

\* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

#### COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. J. Marion Sims, Paris; Dr. H. Macnaughton Jones, Cork; Dr. E. Waters, Chester; Mr. Eastwood, Huddersfield; Mr. Howard Marsh, London; Dr. Edis, London; Medicus; Dr. David Foulis, Glasgow; Dr. Parsons, Dover; Dr. J. B. Bradbury, Cambridge; Dr. Cochran, Edinburgh; Mr. Frederick Scott, Manchester; Enquirer; Dr. Page, Plymouth; A Constant Reader; Dr. Edward C. # A LECTURE ON THE USE OF THE MICROPHONE IN SOUNDING FOR STONE.

*Delivered in University College Hospital, London,  
Tuesday, June 4th, 1878.*

By SIR HENRY THOMPSON, F.R.C.S., M.B.,  
Surgeon-Extraordinary to His Majesty the King of the Belgians; Consulting  
Surgeon to the Hospital.

GENTLEMEN,—My object to-day is to show, as far as I can, how the microphone, a very recent invention of Professor Hughes, may be applied to the operation of sounding for stone. But, in order to make myself perfectly clear to you, it will be necessary at the outset to define one single term, otherwise there is a chance of what I say being misunderstood. I mean the word "sound". This word, as we know, has a technical sense, and signifies the instrument lying before me, the sound; and the verb that arises from it is "to sound"—to sound in the bladder. But the word is also used to represent an acoustical phenomenon, that is the note produced by striking the sound against another body. If I strike this table, I am said to make a sound; but that is precisely the term that I will not use; because, to get into such a sentence as this, "I am going to use that sound to sound a patient, and please listen to that sound", might lead to confusion. Instead, therefore, of speaking of sound, I shall use the word "note" as being the best substitute I can get. If I use the term sound at all, I shall mean this instrument or the manner of using it; when I want to speak of the effect produced, I shall ask you to listen to the note.

Having made that preliminary remark, I have a word or two to say about sounding for stone, independently of the apparatus that is before us. Let me ask you to go back some fifty years—which none of you, however, can do, but which down here some of us are able to do. Forty-five or fifty years ago, sounding for stone was a totally different operation from that which it is to-day; and in my opinion that fact is not half enough appreciated by the profession either here or anywhere else. We have traditional notions of sounding for stone; and if we sound at all with the same intention or in the same manner as our forefathers did, and if we adapt their mode to the exigencies of the present day, we shall meet with nothing but failure. I go further still, and say this, that you might as well compare the famous old Brown Bess with the rifle of precision of the present day, as compare the sounding of 1828 with that of the year 1878.

You will remember that at the time of which I speak there was but one operation for stone. Whether the stone was large or small, there was but one mode in which it could be removed from the human body, and that was cutting—lithotomy as it is generally termed. It mattered little what the size of the stone was, within certain limits. The size of the incision would not vary greatly. A certain incision—dangerous at certain ages, without doubt—had to be made; and whether that were a quarter of an inch or half-an-inch bigger one way or another was not a matter of very great importance. Hence, it was not then a matter of high import that you should discover the stone when it was small. Indeed, it was a common thing in those days for the stone not to be thought of when it was small, and it only came under surgical cognisance when it was large. No one liked to do a great operation to remove a thing about as big as an apple- or orange-pip; and it was common for the surgeon to say (more, however, on the Continent than here), "You have symptoms of stone it is true, but I think it is not ripe for an operation; go away, and come again in a year or two". Patients were thus absolutely put off from month to month, and sometimes from year to year, until the stone should be sufficiently "ripe" for the operation. No one liked to perform an operation unless the stone was nearly of the size of a chestnut. The problem of to-day is an entirely different one. We now have two modes of operating: one of them, as you know, by crushing, in addition to the older one by cutting. The element of success in the operation of crushing is that you should get the stone early, that you should find it small, and then you may make almost absolutely certain of a successful and safe operation. The large stone, as before, will be remitted to the cutting operation, but one may have a much more successful operation in crushing, provided the stone is small. The end of all our endeavours ought to be find the stone as small as possible and remove it in that condition. But that is not the whole problem.

Were it only so, you would see that a much more delicate operation of sounding is required than heretofore; but, inasmuch as the operation of crushing, however small the stone, means making it into fragments smaller still, you will see that it is necessary not only to be able to recognise the small stone by sounding, but also to recognise small fragments of the stone. It is alleged against lithotripsy that, if you leave a small fragment behind after the operation is over, or presumed to be over, that small fragment may become the nucleus of a larger stone hereafter, and you are not only not benefiting your patient, but you have laid a train for more serious mischief. Thus it is that I have all along said that, if lithotripsy be not equal to removing the least fragment which otherwise might be a trouble, it is not an operation to be admitted into the domain of surgery. I would rather cut every case that came to me—I mean with a view to success—than cut only some, and do lithotripsy badly for the others.

There is no perfect lithotripsy, there is no lithotripsy worth your notice or mine, unless it can make absolutely sure of removing every fragment from the bladder. Now, you may say, in view of this which I have before me: "Is it not the case that lithotripsy is equal to that at the present moment? If it be not, why is it that it has stood so high as an operation?" Well, I say, it is equal to it. What I have to show you here is something which will supplement our present power; but, I say it with the greatest confidence, the result of our present power with regard to lithotripsy is, that we are able to remove to the last fragment with unerring certainty, provided the hands in which the case is are fairly (and only fairly) practised. I have demonstrated over and over again, both here and in hospitals abroad, the power of our present instruments to remove the smallest possible fragment. I have, over and over again, obtained an audible note from a piece no larger than a split pea, removing it afterwards to show the truth of the affirmation. You may say: "What more can you want than that?" Well, I think, not much; but let me confess that that is not at present an universally received opinion. There are many persons who still bring allegations against lithotripsy, saying: "It is all very well; you may happen to do this, but it does not lie within the usual practice of surgery to be so certain about that." It is still thought that it is a very easy thing to leave a piece behind. At all events, we will grant this, and we will grant still more, that if we can get anything which will make our task more easy, more simple or certain, it is our duty to add it to our present powers; and I think you will find that we have that in the apparatus before us.

But before showing you what the power of the apparatus is, I wish it to be most distinctly understood that this is not an instrument which is invariably to be used—no, not in more than one case out of twenty. Please understand that the stone is to be found by the ordinary method; and this is, I certainly will not say a surgical or scientific toy, a resource which we have in reserve for exceptional and difficult cases, or for those who may find it perhaps more useful than their unassisted hands and ears. It may be compared to a very high power in the microscope. I need not tell you what great discoveries have been made with the microscope, in every direction throughout nature, with very low object glasses—glasses not to be mentioned in comparison with the high powers which we now use. It is a question how much those extremely high powers have done. They have really done very little. We have at present our fourth, our fifth, and our eighth, within the reach of ordinarily good microscopists; but, when you come to the twelfth and the sixteenth, they can only be used by highly skilled persons, and only here and there can such extremely high powers be required.

Now, the analogy between the microscope and the microphone is very strong. There are many things which we have been in the habit of regarding as without sound, as not producing a note. Nobody, for example, has ever heard a fly walking upon a window-pane. Most persons would say it was noiseless; but it is not so. It simply produces a noise which our unaided ears cannot appreciate. We cut our finger, and we see a little blood. The ordinary eye sees nothing but a little red fluid; nine persons out of ten would be astonished at seeing, under the microscope, what a composite fluid it is—the corpuscles, the liquor, and so on. Just so there are many notes in nature of which we have not the slightest appreciation, but by Professor Hughes's admirable invention we can hear and measure them.

With these observations, and wishing you to understand clearly the place in which I should put this relatively to our surgical armamentarium, I will show you what the microphone is. Here is a battery, with the smallest section employed. If we had used a large section, it would have interfered with the success of the experiment. The current goes up to a telephone, then comes back here, and then goes on to another telephone. It is to be united with the sound, then with this wire, which goes to the other pole of the battery. It does not matter whether you begin with the positive or the negative.

I have here an ordinary sound for sounding a bladder and a microphone upon it. You see a little piece of gas-carbon balanced with a spring, and another piece lying transversely to it. Now, by striking anything with the point of the sound, an acoustic wave goes through the particles of the steel sound and comes up to this piece of carbon. This movable piece receives the impulse, and this now comes into circuit. But it is no longer an acoustic wave; it is transmuted into an electric wave. It suffices to touch a pin; the wave goes up; molecular changes take place which are acoustic in that piece of carbon, and there it ceases; they are then transmuted into electrical waves and are made audible by means of the telephone. Here is the secret of the matter: that, however tiny an acoustic wave is, it may be magnified the instant it becomes an electric wave. I connect these two poles, and, if I rub the two ends of the pieces of wire together, you can distinctly hear the sound by means of the telephone. (Experiment.) The circuit is now complete. I have here an extemporised bladder (a basin lined with wash-leather), and I put in it a small calculus. We will suppose that there is some suspicion that a portion of a stone is in the bladder, or a small fragment left in it. You may push it perhaps, but you cannot feel anything; but, with this instrument, if you touch with your sound a fragment, however small, your telephone will at once speak. I have used the instrument in the bladder, but, unfortunately, I have not a patient here to-day. If I touch but the point of a pin or a finger-nail, the sound is distinctly heard. Some trouble is required in order to get the microphone right for our purpose. In this respect, it is like the aneroid. If you want to measure certain heights with an aneroid—if you want to measure from the sea-level up to five thousand feet—you have one instrument for that purpose, and then for a second five thousand feet you require another instrument. One aneroid will not suffice for the whole range in the case of Mont Blanc, for instance, which is fifteen thousand feet; there you would require a mercurial barometer. The aneroid has only a certain limit within which it is correct. So it is with the microphone. I could put a microphone on this circuit which would be utterly useless. The microphone I have shown you would not enable you to hear the march of a fly. Professor Hughes says that he could make the march of a fly across a piece of net sound like the tramp of an elephant. I have heard a fly walk across a piece of net, with a very audible note. In a public exhibition of the instrument, with an audience, say, of one thousand or one thousand two hundred persons, a large telephone is used—a round trumpet-shaped thing that conducts the notes to the audience. Now, all that is very well in an ordinary lecture, but it is of no use in operating for stone. What I want to show you here is the way in which the instrument may be used in the chamber or hospital-ward. But, as I have said, this instrument is not delicate enough to make the march of a fly audible. If it were, when you put it into the bladder, you would have such a noise from friction from the urethra and bladder that you would not hear the little bit of stone. This is an illustration of the difficulty that often attends the use of delicate scientific things when you come to actual practice. This seems very simple when it is all arranged before you, but it has required some hours' trouble to get it right.

I have an instrument here which is fine enough and delicate enough to hear the sound of a fly; but, if the point of the sound were merely struck against the bladder, it would give a metallic note, just as if it had struck against a stone, so very sensitive is it. It must be borne in mind that you do not get a different note from the different bodies struck. The electric wave merely multiplies or magnifies the wave in the steel instrument; but it does not matter whether you have struck a blanket or a flint, or the mucous membrane of a bladder or a stone; the sound is precisely the same. (Experiment.) Here, if you have too powerful a battery, the friction-sounds would be augmented, and you will not succeed in your effort. Even the echoes of the room may interfere with your operation. I will now put the sound in the extemporised bladder, and, as I touch the little fragment of stone, you will hear a sharp click. It is in dirty thick water, and I cannot tell myself when I strike it; but those of you who listen through the telephone will perceive it.

In a few words, then, the demonstration is this: that you can make absolutely logically certain the existence of small fragments in the bladder, for the detection of which you have hitherto depended upon your unassisted ear and hand. I want particularly to say that the unassisted ear and hand will suffice for almost all cases. There may be one in twenty cases in which it may be necessary or desirable to use this instrument. It is something like the case of the endoscope in regard to the urethra. When it was first introduced, a good deal was said about its being applicable to all disorders of the urethra and the bladder; but it was found in practice that, however well it looked upon paper, there was only a case here and there that might be benefited

by its use. What has mainly actuated me in bringing this subject before you is this. It is obvious that this new invention, which increases the sound of a foreign body, is equally applicable to a bullet or a shot, or any foreign body at the bottom of a wound or a piece of diseased bone. I thought it was desirable that this power should be examined carefully by one who was in the habit of doing something in this way, and it occurred to me that it would be agreeable to yourselves, and certainly gratifying to my own feeling, that the utilisation of the powers of this new invention should be first shown, not at Paris, not at Vienna, but in London, and, best of all, at our own Alma Mater.

I am indebted to Professor Hughes's kindness and courtesy for the microphones which I have exhibited, and for his aid and counsel in the matter.

## OBSTETRIC MEMORANDA.

### CASE OF TWINS AND SPONTANEOUS EVOLUTION.

I was requested to attend Mrs. S., aged 24, during her confinement. This was her fifth pregnancy. On arrival, I was informed that the pains were frequent and of a bearing down character, and, on examination *per vaginam*, I found the head presenting in what is known as the fourth position; that is, the long diameter of the head occupies the left oblique diameter of the pelvis; here the forehead is close to the right foramen ovale, while the occiput is directed to the left sacro-iliac synchondrosis; the anterior fontanelle is directed to the former, the posterior to the latter. As the case progressed, the occiput turned into the hollow of the sacrum, and the forehead was directed to the symphysis pubis, and eventually it emerged under the pubic arch, followed by the eyes, nose, mouth, and chin. On the birth of the head, the cord was found coiled once round the neck; while I was drawing it down and hooking it over the head, the uterus acted strongly, and the child was born. After tying the cord and waiting for a few seconds, I made a vaginal examination, and found the placenta in the vagina, and by its side the left arm of a second child. The uterus was acting so strongly and continuously that the membranes were ruptured, the placenta, which appeared to have a vascular connection with each other, were expelled, and the child was jammed down into the pelvis, so that it became impossible to turn. The pelvis being roomy, and believing the child to be small, and seeing that the thorax was well down in the hollow of the sacrum and the axilla, almost on a level with the lower edge of the pubes, the pains being strong, I thought it best to leave the case to nature, and was not disappointed; for the thorax became lower at each pain, followed by the side of the abdomen, and, lastly, the pelvis and lower extremities, the arm and shoulder remaining fixed all the time. On slight traction being made with the fingers hooked over the shoulders, the head soon followed, and the second child was born just thirty minutes after the birth of the first. Both were girls; the first lived, but the second, I need hardly say, was dead. This was, no doubt, due to the separation and extrusion of the placenta prior to the birth. The principal points in this case were, first, the rather unusual presentation of the head of the first child, and its being born with the face towards the pubes; secondly, the rapid expulsion of both placenta prior to the birth of the second child; and, lastly, the very rare position of the second child, which might be placed in the list of cases under the name of spontaneous evolution.

DAVID S. BRADLEY, M.D., Chesterfield.

### PLACENTA RETAINED ONE HUNDRED AND TWENTY-THREE DAYS AFTER MISCARRIAGE.

MRS. P. miscarried on December 3rd, 1867, when a three months' fetus was expelled. The placenta could not be removed. There was a continual, thin, sometimes pale, often very red discharge, with occasional little clots of blood. On April 2nd, 1868, I found a globular mass presenting at the os uteri; the os dilated to the size of a florin. I could not grasp the presenting body, but managed to rotate it with the finger. This seemed to loosen it. I gave ergot in fifteen-grain doses of the powder. After taking the ergot for twenty-eight hours, the placenta came away. It weighed about three ounces; its fetal surface was folded on itself. The mass was a pointed oval; the maternal surface pale straw-colour; the substance more dense than the ordinary placenta. *There were no signs of putrefaction whatever.* This case, like those in the JOURNAL of the 4th and 18th ult., has some interest, I think, especially in a medico-legal sense; and therefore I send it to be in company with the previous cases.

FREDERICK W. P. JAGO, M.B.Lond., Plymouth.

## REMARKS

ON

## CHOLECYSTOTOMY IN DROPSY OF THE GALL-BLADDER.

By J. MARION SIMS, M.D.

Honorary Fellow of the Obstetrical Societies of London, Dublin, and Paris;  
Ex-President of the American Medical Association; etc.

AN American lady, aged 45, living in Paris, was married at twenty-three, and had one child, now nineteen years old. She had change of life at forty-three, without any constitutional disturbance. A woman of fine intellect and fine appearance, weighing one hundred and sixty pounds, she had enjoyed uninterrupted good health all her life. Her family history was excellent, and her regular habits of living were such that she had not consulted a physician for the most trifling ailment in the last twenty-five years. Besides all this, she was most happily married and enjoyed every comfort and luxury of life that wealth, friends, and a loving husband could bestow. But at last a great sorrow fell upon her, and her husband wisely suggested change of scene, and she spent the months of August and September 1877 in Switzerland. While there, she complained of the cold, and occasionally of pain in the right lumbar region, high up under the false ribs. For the last twelve months, she had now and then complained of pain in the right hypochondrium, when she stooped over to button her shoes, but not under any other circumstances. She returned home in October, not much improved in health; and, in the later part of November, she became suddenly jaundiced. In two or three days, the jaundice was of a *deep mahogany colour*. She complained of languor and debility, but of no pain. Her husband and friends wished her to consult a physician, but she refused, saying she was not at all ill, and she supposed the jaundice would disappear spontaneously, as it was not attended with physical suffering. The jaundiced tint became deeper, and at last she agreed to see a physician, and Dr. Felix Bremond was called on December 5th, 1877. He prescribed the usual remedies under such circumstances, but with no marked improvement. On December 30th, Dr. Moissonet and Dr. Paquelin saw her with Dr. Bremond, and they discovered some unnatural swelling about the lower border of the liver. They saw her again with Dr. Bremond on January 7th, 1878. On January 8th, on going to stool, she had a sudden discharge of clear uncoagulated blood from the rectum. The discharge of blood was preceded by a gripping pain around the umbilicus. She had passed a mass of coagulated blood from the bowels some days before; and for several days since then she had been passing small quantities of blood, which were always preceded by a gripping pain about the umbilicus, but she attached no importance to it and said nothing about it. Dr. Bremond, supposing that the blood came from the hæmorrhoidal vessels, at first tried astringent injections, but without effect. He then prescribed perchloride of iron, which appeared to control the bleeding; for on the 10th and 11th it was less, but on the 12th and 13th it was more profuse. The dose of the perchloride was then increased, and the bleeding ceased on the 17th. But it appeared again on the 18th, on the 21st, and occasionally up to January 30th, when it ceased entirely. During all this time, she took the perchloride of iron. On December 6th, about a week after the jaundice set in, she began to suffer from intense itching and burning of the skin, which were almost unbearable, and she occasionally had lancinating pains darting like electric shocks through the joints. The itching and burning were so severe that they prevented her from sleeping. They were always worse in the afternoon and evening. Dr. Bremond tried emollients, baths, anodynes, and nervines, with no permanent effect. The heat of the bed seemed to aggravate the itching, and then, if her arms and legs were uncovered, the exposure to the air made it still worse. It was most painful to witness sufferings that could not be relieved. She would often rest for hours on her knees and elbows to save her body from contact with the bed; and again, she would spend the night walking the floor, scratching, and crying like a child. Ordinarily she had great moral courage, but she lost it all under this uncontrollable itching and scratching. Every part of the body was the seat of itching, the scalp, and even the inside of the eyelids. She was never clear of it, but it was

always worse in the afternoon, especially towards five or six o'clock. About the middle of February, it became less in the lower extremities, but the upper extremities and the body suffered as usual. In addition to the itching and burning, there was great hyperæsthesia of the skin. Sometimes, when one hand accidentally touched the other, she would suddenly jerk and quiver as if an electric spark had passed between them. The hyperæsthesia was occasionally so aggravated that she could not bear the weight of the bedclothes, or a gentle touch; while again, the itching was so intolerable that she was compelled to scratch with great violence. She was never clear of the itching and burning sensation in the skin, which was occasionally attended with what is known as "goose-flesh" roughness, with a sense of internal chilliness, but she never had distinct rigors. She passed whole nights without sleeping, simply because of the itching and scratching. No remedy, internal or external, produced any permanent benefit.

On January 15th, 1878, Dr. Noël Gueneau de Mussy saw her in consultation with Dr. Bremond. The swelling in the right hypochondrium had increased, and was now easily recognised as a distinct tumour. For some time, she had complained of constant aching pain and weight in the tumour, extending back to the right lumbar region, with occasional pain under the right shoulder-blade. The pain in the tumour was sometimes lancinating, and, when she turned in bed, she was always conscious of the movement and pressure of the tumour. From this time, Dr. Bremond could see that the tumour grew from day to day. She had had nausea and vomiting from time to time, but now she vomited almost daily. From the inception of the jaundice, her stools had always been clay-coloured, except when they were bloody, and their odour was very offensive.

On February 7th, Dr. Labbé was called in consultation with Dr. Bremond and Dr. Gueneau de Mussy; but, in spite of their best efforts, there was no amelioration of suffering. The previous loss of blood and loss of sleep from itching, the continued enlargement of the tumour and the constant pain, the inability to take food in sufficient quantities, and the daily vomiting, all conspired to produce a physical and moral depression that created great anxiety. It is useless to give a daily report of the progress of the case. All days were bad and all more or less alike. The same itching and burning, the same sleepless nights, the same offensive clay-coloured stools, the same pain in the tumour, in the right lumbar region, and under the right shoulder-blade, with occasional vomiting, were suffered every day. Our patient, from being a stout handsome woman, became thin and emaciated; and was jaundiced, from the second day after her first attack, of a deep-brown mahogany colour. The urine was always scanty, intensely high coloured, and gave a bile tinge to the sides of the vessel when shaken. Besides Dr. Moissonet, Dr. Gueneau de Mussy, and Dr. Labbé, she was seen by Dr. Péan, Dr. Bouchut, Dr. Paquelin, and Dr. Dusserris.

I saw the patient with Dr. Bremond on March 30th, and obtained the history already given. The tumour, which was continuous with the liver, filled up the right hypochondrium, reaching far below the umbilicus; and Dr. Bremond showed me two diagrams, one made on March 6th and the other on the 16th, which plainly demonstrated the size of the tumour and the rapidity of its growth.

On March 6th, it extended eleven *centimètres* (four inches and a quarter) below the umbilicus, and it was eleven *centimètres* in its transverse diameter.

On March 16th, it extended fourteen *centimètres* (five inches and a half) below the umbilicus, and it had the same transverse diameter, measuring from the linea alba toward the false ribs. To the sight, the right hypochondrium was much larger than the left. The tumour was oblong, rounded, and slightly movable laterally. To the touch, it was sensitive and hard, or tense. The tension was so great as to mask fluctuation; still, I detected fluctuation, and gave it as my opinion, that it was a cyst connected with the liver, but whether hydatid or dropsy of the gall-bladder I could not say. But I advised aspiration as a diagnostic means to guide subsequent treatment. Dr. Bremond at once agreed to this course. Accordingly, on the following day, assisted by Dr. Bremond and Dr. Platt, the tumour was aspirated, and thirty-two ounces of a dark-brown fluid were evacuated. From the colour of the fluid, I supposed it was bile. But an analysis showed that there was no bile in it and no hydatid hooks. The immediate effect of emptying the tumour was greatly encouraging. She was relieved of all pain in the region of the tumour and liver. She slept all night and a good deal during the following day. There was no vomiting, and she had no itching for two days. She was able to take fluid nourishment, and the pulse and temperature were normal. But the urine was scanty (eighteen to twenty-four ounces a day) and very high coloured. These favourable symptoms did not last long. Two days after the aspiration, she complained of itching again in the upper extremities, of pain in the right lumbar region and under the right shoulder-blade, and of nausea.

Her stools had the same fearful odour, and were always whitish or clay-coloured. She gradually became weaker, sleeping but little, worn out with itching, and prostrated for want of nourishment. On April 8th, nine days after the puncture, she had a slight bleeding from the nose.

April 9th. She was very nervous, and crying from the pain of itching, and felt sore all over from scratching; nauseated; exceedingly feeble; she fell into a sort of stupor, which was afterwards ascertained to be syncope. She had several of these attacks of syncope, with nausea and exhaustion, and Dr. Bremond was obliged to remain with her nearly all night. With the syncope, she had pain in the stomach, also about the umbilicus, and a sense of coldness; and towards morning she had hiccough, cold hands and feet, and vomiting, with complete prostration, the pulse being frequent and feeble. This state of prostration passed off in about twenty-four hours, when the skin became warm and the pulse normal. She passed no urine during all this time. Having been called from the city, I did not see our patient after the aspiration till April 13th, just a fortnight. I found her much weaker, and suffering as usual with itching, nausea, vomiting, and having stools of the same colour and odour as before; and she complained very much of the tumour, which was now nearly as large as before the puncture. It was heavy, and dragged as she lay or turned in bed. It was more sensitive on pressure than ever before; indeed, there was such a degree of sensitiveness that she could hardly bear to be touched. There was considerable tympanites, and a deep breath greatly aggravated the pain in the tumour. She also complained of the same old pain extending from the shoulder-blade down the right lumbar region. The pain in the tumour was so much worse—there was so much tenderness on pressure—such evidence of inflammatory action, with such a degree of prostration—that Dr. Bremond and myself, looking upon the case now as hopeless, agreed to cut down on the tumour, freely open it, empty its contents, and, if it proved to be the gall-bladder, to attach its incised border to the edges of the abdominal incision, and thus to make a fistulous opening that would insure against its refilling. We were encouraged to make a permanent fistulous opening, because, first, we saw such improvement in all her symptoms follow the temporary removal of the fluid by aspiration; second, it would be in imitation of the efforts of nature in all similar cases where recovery has taken place; and third, speedy death was inevitable if we did nothing.

*Operation.*—April 18th, 10 A.M. There was great tenderness and pain in the region of the tumour, aggravated by pressure. For the last three or four days, there was marked tympanites. The pulse had risen from 75 up to 110 and the temperature to 100 deg. Her sufferings were altogether so much worse than they had ever been before, that she implored us to lose no time in giving her the relief she expected from the operation. Dr. Hayden gave ether, and Dr. Bremond and Dr. Pratt assisted me. The operation was performed under proper antiseptic precautions, with carbolic spray, and carbolic lotion for hands, sponges, and instruments. It took an unusually long time (twenty-four minutes) to get the patient under the influence of the ether. An incision, three inches long, parallel with the linea alba, was made over the most prominent part of the tumour, about three inches to the right of the umbilicus. It was begun an inch above the level of the umbilicus, and extended two inches below it. The peritoneal membrane was soon reached, but was not opened till all bleeding from divided vessels was controlled. As there was such a hemorrhagic tendency, this required six artery forceps on each side of the incision. When the peritoneum was opened, several ounces of pinkish serum (perhaps six or eight) were discharged. I am somewhat in doubt whether the pinkish colour of the serum was due to the rupture of recent adhesions between the cyst and the parietal peritoneum, or to osmosis from the peritoneum. But I think it was from the latter cause; for I did not, by sense of touch, discover the adhesions, if any existed. A Dieulafoy's trocar of the largest size was thrust into the tumour, and twenty-four ounces of a dark-brown fluid withdrawn, which I supposed to be bile. As soon as the cyst was emptied, it was hooked up with a tenaculum and pulled to the outer edge of the incision, where it was seized with forceps and drawn out for about two inches. It was there held while the finger was passed into the peritoneal cavity, along its under and upper surfaces, when it was ascertained, by its attachments to the liver, to be the gall-bladder. Dr. Bremond, Dr. Pratt, and myself each thoroughly explored the sac by touch, and satisfied ourselves that it was the gall-bladder. This multiple manual investigation would have been unjustifiable and hazardous without antisepticism. The gall-bladder was then incised with scissors, to the extent of about two inches, and was thoroughly cleaned out with sponge-probings passed to the bottom of the sac, which, on measurement, was found to be eight inches deep. At first, there were removed about two ounces of a dark-brown fluid, much thicker (containing more mucus) than that already drawn off; and then there were drawn out with the probang a half-dozen or more gall-stones. One

probang after another was then passed in, and swept around, till sixty gall-stones were removed.

Having emptied the gall-bladder, it now only remained to secure its open border to the upper angle of the abdominal incision to insure a fistulous outlet. As it was already drawn out through the incision to a considerable extent, I resolved to amputate the projecting portion, which was a mistake. Its walls were greatly thickened, and bled when cut, so as to require the use of several artery-forceps. The puckered mouth of the amputated cyst was then crowded into the upper angle of the abdominal incision, and there secured with eight fine carbolised silk sutures, taking good care to pass each suture through the whole thickness of the abdominal walls, including the peritoneum. After this process was finished, we waited several minutes with small carbolised sponges (on probangs) resting just within the cavity of the peritoneum, to be sure that there was no bleeding from the needle-punctures. When we were satisfied on this point, the lower portion of the abdominal incision was closed with fine carbolised silk sutures, including the peritoneum. The whole wound was then covered with some cotton-wool saturated with carbolised oil, over which was placed a large compress of fine cotton-wool secured with adhesive strips and a flannel binder. When the wound was closed, there still remained a considerable quantity of pinkish serum in the peritoneal cavity, such as I formerly thought to justify the use of a drainage-tube. But the experience of Bantock and Thornton at the Samaritan Hospital proves pretty conclusively that drainage is not always necessary under Listerism, because it prevents putrefaction, and the reddish serum is absorbed without producing septic symptoms.

The operation lasted one hour and sixteen minutes, exclusive of the time consumed in getting the patient etherised. The most tedious part of it was in securing the cyst in the incision and closing up the wound. This took up all of thirty-five minutes. The patient recovered from the anesthesia half an hour after the operation, and vomited once from its effects, and then lay quiet and comfortable, sleeping a good deal during the afternoon; and she slept all night.

April 19th, first day after operation.—The pulse and temperature were normal; there was no pain and no fever. Dr. Hayden remained all night, but was not called up. She took nourishment at stated intervals in sufficient quantities. She was free from pain; her pulse and temperature were good. She slept; had no nausea or vomiting. She had passed twenty-five ounces of dark brown urine in the twenty-four hours, which gave the tint of bile to the sides of the vessel when shaken; and the stools even became natural in appearance and odour, looking as if they might have been passed by a child. Taken altogether, her condition was good.

April 20th, second day.—There was a slight discharge of brownish fluid from the wound, or rather from the gall-bladder.

April 21st, third day.—She had passed a good night, sleeping and resting well. Her mind was clear, her memory good, and she was very bright and hopeful. She reminded her husband this morning that this was his birthday. There was no itching.—9 A.M. A little brownish fluid was passing from the wound.—5 P.M. The wound was dressed for the first time, and under carbolic spray. It had healed perfectly. The edges of the sac adhering to the upper angle of the incision looked greyish, as if the circulation had been obstructed by constriction. In the last twenty-four hours, she had passed but fourteen ounces of high-coloured brownish urine.

April 22nd, fourth day.—Her condition was satisfactory; she had slept well. She had passed nine ounces of urine during the night of the same deep brown colour. She complained of dryness of the mouth.

April 23rd, fifth day.—She had had a good night's sleep. Her pulse and skin were natural. She felt stronger. She had a natural stool.—5 P.M. Pulse 80, temperature 100. She had passed seventeen ounces of urine in the last twelve hours.—9 P.M. The tongue was red and dry, and blood was oozing from the gums and tongue. Six ounces of urine had been passed.

April 24th, sixth day, 8.30 A.M.—The nurse said she had a bad night.—8.45 A.M. The discharge from the wound was mixed with blood.—9 A.M. The wound was dressed. The abdominal incision below the fistula of the gall-bladder was perfectly healed. There was no pus about the sutures, which were allowed to remain. There was a little oozing of blood from the edges of the gall-bladder. Some cotton-wool charged with iron was placed over this point, and pressed down with a sponge held in position with strips of adhesive plaster. The oozing of blood from the gums increased.

April 25th, seventh day, 3 P.M.—Again there was oozing of blood and dark brown fluid from the wound, and it was again dressed with iron cotton-wool and a sponge-compress. Ergot was ordered to be injected hypodermically every four or five hours, with the hope of controlling the exudation of blood from the mucous membrane. Up to this time,

I expected our patient to recover; but when I saw the blood exuding continually from the mouth, I told the husband it was a serious symptom, and that in all probability the same thing would take place in the stomach, and that death would occur from black vomit, just as it does from yellow fever. The ergot was continued for twenty-four hours, and then we resorted to the hypodermic injection of dialysed iron, but without any amelioration of the bloody discharge from the gums.—5.30 P.M. Pulse 98; temperature 100.2.

April 26th, eighth day, 7.30 A.M.—She vomited six ounces of a dark coffee-grounds fluid, having all the appearances of black vomit of yellow fever.—9.15 A.M. She vomited again one ounce and a half of black vomit, in which blood was plainly visible. Pulse 100, feeble; respiration 26; temperature 99.6. From this time, she gradually sank, and died at 4.25 P.M. on April 26th, eight days and six hours after the operation.

Saturday, April 27th, 6 P.M.—Embalment and partial necropsy by M. Ganai, twenty-six hours after death. Besides M. Ganai and his assistants, there were present the Commissaire de Police, Dr. Bremond, Dr. Hayden, and myself. The body was much emaciated. Rigor mortis was well marked. The skin was everywhere of a deep orange mabogany tint. The abdomen was tympanitic, evidently *post mortem*. On the back, there were several bullae, varying in size from one to two or three inches in diameter, which, when opened, discharged bloody serum. A fluid similar to black vomit, showing granules of blood, had been running from the nose, and stained the right side of the face.

On removing the dressing from the wound, a dark brown fluid was discharged through the fistulous opening in the gall-bladder. On close examination, the abdominal incision was found to be perfectly united, and there was no pus around the sutures. M. Ganai made an incision from the ensiform cartilage to the pubes, and cut down to the peritoneum. Thinking he had cut through the peritoneum, he began to separate it from the abdominal parietes, saying: "Here is peritonitis with adhesions everywhere." I told him to open the peritoneum, which he did, and found that there was not the slightest evidence of peritonitis. The intestines all had a bloodless pearly appearance, almost diaphanous. M. Ganai then made an incision from the ensiform cartilage at right angles with the longitudinal one, in a direct line across the right hypochondrium, and another incision from about two inches above the pubes, across the right hypogastrium to the spinous process of the ilium. The three-sided rectangular flap of abdominal wall thus made was raised up and turned back over the edges of the false ribs on the right side, showing the gall-bladder firmly adherent to the walls of the abdomen, where it had been attached by the sutures at the time of the operation. M. Ganai then passed a director into the gall-bladder through the external fistulous opening, showing the continuity of the two. After satisfying himself that the operation had been successful in this respect, he cut the gall-bladder loose from the parietes of the abdomen, and then introduced his hand into it, and removed sixteen gall-stones from the size of a pea to that of a pigeon's egg. They were all sacculated, and this was the reason that they were not removed at the time of the operation. He then removed the gall-bladder entire; it was very large, and its walls were much thickened. After doing this, he was able to pass a probe from the gall-bladder through the ductus communis choledochus into the duodenum. The inner surface of the gall-bladder was very dark-coloured, almost black; but its structure was so firm that it could not be scraped off with a knife. On cutting into the substance of the liver, large quantities of serosity ran out, and its bile-ducts were much enlarged, as plainly seen by the naked eye. The stomach contained a large quantity of dark flocculent coffee-grounds fluid, which in yellow fever is called black vomit, and so did the small intestines. The mucous membrane of the stomach and small intestines was pearly white, with no patches of inflammation or ulceration to account for the exudation of the black bloody fluid. The sigmoid flexure, at its junction with the rectum, contained faeces of natural colour and consistence.

In the Douglas's *cul-de-sac*, there was about an ounce of uncoagulated blood, which appeared to have come from a little erythematous patch on the peritoneum, near the lower end of the sigmoid flexure. M. Ganai thought the fluid blood had passed from this point by osmosis. On the inner surface of the bowel, just opposite this elevated point in the peritoneal coat, the mucous membrane, for half an inch in diameter, was thickened, elevated, and had a papillated appearance, and it was supposed that this point might have been the seat of the prolonged bleeding that occurred between the 5th and 30th of January.

The contents of the gall-bladder, a piece of the gall-bladder, and the vomited matter were sent to M. Ranvier, Professor of Histology in the College of France, for examination, and the following is the report.

"Calculus cholecystitis and dropsy of the gall-bladder. Microscopical examination of the gall-bladder, its contents, and of the matter vomited.

A. *Microscopical examination* showed that this membrane was composed of three layers, easily distinguished even when feebly magnified, although they were not distinctly separated from each other.

1. An external connective layer resembling the subperitoneal cellular tissue.

2. A middle fibrous layer intermixed with fasciculi of smooth muscular fibres crossing each other in every direction. This layer was also supplied with vessels, the arteries and veins being quite large.

3. An internal layer, whose deepest parts continued imperceptibly with the preceding. It consisted of a granulated tissue (Virchow); viz., of embryonic elements, in the middle of which vessels might be seen very much congested and furnished with walls, which were still themselves in an embryonic condition. In many points, the walls of these vessels were ruptured, from which small hemorrhages had resulted. There existed no trace of epithelial covering at the surface of the layer, nor was there to be seen in its thickness the presence of a single glandular tube.

B. *Liquid contained in the Gall-Bladder*.—This liquid was transparent and slightly tinted with red. After a minute examination, no trace of echinococci could be found, nor any striated membrane. Therefore, it was not from a hydatid cyst. A large number of red corpuscles were seen, which had preserved their natural form and colour. We will see later the importance of this fact from a pathological point of view.

C. *Gall-Stones*.—These were composed, as usual, chiefly of cholesteroline.

D. *Vomited Matter*.—The contents of both tubes, although vomited at different intervals, presented under the microscope the same characters. They consisted of a liquid, somewhat viscous and of a green colour, caused by the bile. On examining the deposit, which was abundant and also of a deep green colour, the following elements were observed.

1. Epithelial cells of different forms, the greater number being in the form of prisms of a green olive colour, caused by the biliary pigment. The colouration was uniform.

2. Isolated and conglomerated granulations of the colouring matter of the bile (biliverdin) formed blocks of considerable size.

3. Lymphatic cells infiltrated with little drops of mucus.

4. Vibriones and bacteria of different species: *Bacterium punctum*, *termo*, and *catenula*.

5. A number of red corpuscles very much altered, and well known by their pale circle and double outline.

On adding acetic acid to the liquid, a deposit was formed which had the characteristics of mucin. No sarcinae ventriculi were found.

*Conclusions*.—1. The microscopical examination, and also the *post mortem* examination, allow us to conclude that the walls of the cyst-pocket belonged to the gall-bladder. The alteration which it had undergone does not, it is true, permit me to recognise either its villousities or its epithelial lining; but the structure of its middle and external layers is sufficiently characteristic. As to the glands, we know that their existence outside of the portion near the neck is very uncertain (Kölliker). The alteration which has taken place in the gall-bladder manifests itself on the mucous lining, and is purely of an inflammatory character. It is transformed into a granular tissue similar to that of fungus-granulations, composed of embryonic elements permeated with vessels of a new formation, whose walls are also in an embryonic condition. These lesions are identical with those we find in cases of obliteration of the canal of the gall-bladder (calculous cholecystitis).

2. The liquid contained in the dilated gall-bladder offers an example, not of colourless bile, but of dropsy of the gall-bladder, from which we are able to draw two conclusions.

a. Sometimes the gall-bladder contains a colourless liquid, still having the bitter characteristic of the bile, and in which, by the reaction of Pettenkofer, we are able to recognise the existence of biliary acids.

b. Sometimes, on the contrary, the liquid contained in the gall-bladder, also colourless and viscous, is deprived of the bitter principle of the bile, and a chemical reaction shows not only the absence of the colouring matter, but also of biliary salts. Cases of this kind are not rare. We find them mentioned by Cruveilhier (*Atlas d'Anatomie Pathologique*), who gave them the name of dropsy of the gall-bladder (Frerichs, *Traité des Maladies du Foie*; Moxon, *Pathological Society's Transactions*, 1870, vol. xxiv). They occur in many cases of occlusion of the bile-ducts, whatever may be the cause.

In the case related by Frerichs, the liquid which dilated the gall-bladder and biliary canals was transparent, slightly mucous, and a little alkaline. The reaction of Pettenkofer could not be obtained.

Under the microscope, a large number of mucus-corpuscles were found, and, by the addition of acetic acid, a precipitate characteristic of mucin was formed.

It is generally admitted, in order to explain the substitution of this liquid (different from the bile) for the bile, that the bile, for a long time retained and submitted to a considerable and increasing pressure, is absorbed, and a sero-mucous liquid, secreted by the mucous glands and the epithelial covering, takes its place. This is also the opinion of Professor Charcot (*Leçons sur les Maladies du Foie*, 1876).

If we now ask ourselves what is the nature of the liquid under consideration, and which so distended the gall-bladder, notwithstanding the absence of a chemical examination, we will find an answer to our question by the preservation of the red corpuscles in the liquid. Every one knows, since the researches of Kühne (*Zeitschrift für Wissenschaftlichen Zoologie*, vol. ix, p. 261), that the bile, and particularly the biliary salts, destroy the red corpuscles, which first become pale and then disappear suddenly without leaving a trace. On this fact, which is very easy to verify, Kühne established a theory of malignant jaundice (*ictère grave*), which resulted from the destruction of a large number of red corpuscles by the biliary acids which were absorbed by the mucus of the intestine. Therefore, the presence of red corpuscles intact in this case is a certain proof that, in the liquid which contained them, there was not an appreciable quantity of biliary salts, and consequently it was not itself colourless bile.

(Signed) E. CHAMBEARD, Interne des Hôpitaux, Répétiteur au Collège de France."

Like many others who have not given special study to the diseases of the liver, I supposed that dropsy of the gall-bladder meant a gall-bladder distended with bile; and when the chemist made the analysis, showing that there were no hydatid hooks and no bile in the fluid, I was amazed. So, when the operation of cholecystotomy was performed, I took care to have the highest authority on the subject; and I have now great satisfaction in submitting Dr. Chambard's report, which not only shows that the distended inflamed gall-bladder contained no bile, but gives the reasons why it did not.

Although this case terminated fatally, I look upon it as a triumph for Listerism; for the *post mortem* examination proved that there was not the least trace of peritonitis or other untoward complication to be found as the direct result of the operation.

The benefit of the operation was shown in the immediate relief of pain, itching, nausea, vomiting, and in the production of stools natural in colour and odour. Death occurred, as it usually does in all such cases depending upon total occlusion of the bile-ducts, from transudation of blood from the mucous surfaces, *i.e.*, from passive internal hæmorrhage, the result of the poisonous effects of the biliary salts on the blood.

I believe that this operation is unique. Is it justifiable? I think it is, because it is in imitation of the process adopted by nature in all cases in which recovery takes place. Death is absolutely certain in every case where the gall-ducts are mechanically obstructed, unless an outlet be obtained either into the alimentary canal or by a fistulous opening externally through the abdominal walls. All authors have advised against opening the gall-bladder until nature had prepared the way by forming adhesions between it and the abdominal walls, or till this had been done artificially by caustic potash. But this case proves that it is not necessary to wait for the tedious efforts of nature, on the one hand, or to resort to the clumsy process of caustic, on the other. Dieulafoy's aspirator renders the diagnosis certain, and antisepticism renders the operation of cutting down to the dropsical gall-bladder and establishing a fistulous opening quite as safe as to leave it to the slower process of nature. The propriety of the operation being established, we can hereafter resort to it at an earlier period, before the changes are effected in the blood by the bile-acids which lead to its extravasation from the mucous surfaces. The blood of our patient was already so changed, so impoverished by the toxic action of the bile, that the operation was nugatory in staying the fatal result. Fortunately for progress, the clinical history of the case and the *post mortem* examination establish beyond any question the safety of the operation *per se*.

It is too much the fashion now-a-days to coin new names for old operations. But, as this is a new operation, we must find a name for it. And I think cholecystotomy (χολή, gall; κύστις, bladder; τομή, incision) will answer. It is not necessary to encumber the name with the prefix "laparo", which is now used to designate operations through the walls of the abdomen, as there is no other route by which we could reach the gall-bladder. Were I called upon to operate again under similar circumstances, I would not procrastinate it a day after the diagnosis was fully established. For it is certain that the longer it is put off the more the blood becomes poisoned by the bile, and the more the chances of recovery are diminished.

I would perform the operation precisely as I did, except in this particular. I would not remove any portion of the gall-bladder; I would draw the gall-bladder, after emptying it, to the surface, open it longitudinally with scissors for an inch or two, seize each side of the incised part with spring-forceps, hold it firmly, then clear it out with sponge-probings, as I did in this case, or throw in a stream of carbolic warm water through a gum elastic catheter introduced to the deepest part of the cyst. By this means, I would expect to remove the gall-stones by the returning force of the injection with greater ease and with less manipulation than by the sponge-probings. It is a mistake to pull the gall-bladder through the abdominal incision and amputate any portion of it, because it will be found much thickened, and the removal of a segment of it leaves a large opening to be crowded up into the superior angle of the incision, there to be secured by sutures. It will answer a better purpose simply to incise the gall-bladder, as before said, than to remove any portion of it.

Since the time of Borrichius in 1676, cases of dropsy of the gall-bladder, complicated with gall-stones, resulting in abscess and a fistulous opening externally, have been frequently observed. In many cases, recovery has taken place even in very old people. In some, death followed often as the result of black vomit; in others, the discharge of bile through the fistula continued for a long time without detriment to the general health. In many, the fistulæ were eventually closed up, and in almost all of them gall-stones, in greater or less numbers, were discharged; some of them small and some of great size. As death so often occurs from impacted gall-stones, the question of surgical interference has more than once been raised. And recently Dr. Handfield Jones has revived the question. In speaking of the passage of gall-stones through the ductus communis choledochus, he says (*Medical Times and Gazette*, March 9th, 1878, p. 247): "I made the proposal, when danger became imminent, to one of my surgical colleagues to open the abdomen, and endeavour by manipulation to force the calculus out of the duct into the bowel. He declined the responsibility of such operative interference, and so the idea was given up. After death, before the necropsy was commenced, I tried to ascertain how far it would have been practicable to execute the proposed manœuvre. I found the calculus in the anticipated situation, but could not positively determine that it was such or an enlarged gland, nor could I press it forward. However, if I should meet with another like case, I should be much disposed to advocate the operation, as it might save life."

Mr. Spencer Wells and other ovariologists constantly make exploratory incisions into the abdominal cavity to determine the nature of doubtful tumours, and hardly give it a serious thought, as the operation is done with great impunity; and I am sure that, under antiseptic precautions, Dr. Handfield Jones's idea of opening the abdomen and exploring for gall-stones can be and will be carried out with the same impunity, and with the faith that, if it fail to save life, it will certainly not shorten it.

Given a case of persistent jaundice, with clay-coloured stools, nausea, and itching, we may almost certainly infer that there is mechanical obstruction of the ducts of the gall-bladder. Why, then, should we wait for months for the gall-bladder to become dropsical and to swell up into an enormous tumour filling the right hypochondrium, and extending even to the iliac region? Why not open the abdomen, explore the condition of the liver, and, if we find gall-stones, why not open the gall-bladder, remove the gall-stones, and sew up the incision in the gall-bladder with the same security, the same confidence, that we would stitch up a wound of the intestine? There is no reason why it should not be done, and it will be done; so it will eventually be seen that the operation of cholecystotomy, joined with Dr. Handfield Jones's proposition, will open up a new field in the great domain of abdominal surgery.

I do not know that itchiness of the skin is a common symptom of ordinary accidental jaundice. When I practised medicine in Alabama forty years ago, I frequently saw cases of jaundice; but I do not remember that they were attended with inveterate itching. I had jaundice myself in 1847, as a sequence of yellow fever; but I did not suffer from the peculiar itchiness that belongs to jaundice from mechanical obstruction of the gall-ducts.

Murchison says that itchiness is rarely observed, except in cases where the jaundice is due to the obstruction of the bile-duct. From recent investigations into the literature of the subject, I am led to think that inveterate itchiness, jaundice, and absence of bile from the stools conjoined will be found to be pathognomonic of mechanical obstruction of the bile-ducts. If this could be established as a law, then it would greatly aid us in determining such cases as might be promptly brought under surgical treatment. There is a difference of opinion amongst authors as to the cause of itching. It has been variously conjectured to depend in some way on the bile-pigment or bile-acids deposited in

the rete mucosum. If this be the case, then, we ought to find it in ordinary jaundice of a temporary character. In the case I have related, the itchiness was an early symptom, and it became intense, and remained so up to the time the gall-bladder was aspirated on March 30th. The sudden removal of the fluid from the gall-bladder by aspiration took off the pressure, and the itching was relieved for two days; but, when the gall-bladder began to refill, the itching returned, and soon became a troublesome symptom. By the aspiration on March 30th, there were removed thirty-two ounces of fluid; by the operation on April 18th, there were removed twenty-four ounces of fluid; by this operation, all the fluid and all the free gall-stones (sixty) were removed, and a fistulous opening was established through which the dropsical fluid of the gall-bladder could and did escape in certain quantities. Now, after this operation, the itching never returned, and yet the skin was of the same deep brown mahogany colour that it was before the operation. If this colouration be due to bile-pigment, as we all believe, and if the itching be due to the direct action of the bile on the sensory nerves, why was the itching so modified by aspiration, and so perfectly relieved by the operation of establishing a fistulous opening for the constant discharge of the contents of the gall-bladder? This leads to the inference that the itching is not due to the irritating effects of the bile locally, but is a reflex symptom; that it depends more upon the pressure of distension; for we see, in this instance, that the temporary relief of the pressure and distension was followed by temporary relief of the itching; and that the permanent relief of the pressure and distension was followed by permanent relief of the itching. As death occurs often in this affection from passive hæmorrhages, so clearly the result of cholætoxæmia, it would be fortunate if we could diagnose it in its early stages, so as to resort to a radical treatment before the blood became so poisoned as to preclude the hope of cure.

The history of this case shows that the tumour was discovered on December 30th; that is, about one month after the jaundice set in. It then presented all the characteristics necessary for a complete diagnosis. But all our authors, without a single exception so far as I know, positively forbid any surgical interference until the tumour is found knocking at the abdominal parietes for the exit of its contents. Guided by the highest authority amongst us, we were not justified in performing any operation, except as a *dernier ressort*; and it was then done too late, as our patient died precisely as she would if no operation had been done. But, guided by the experience gained by this case, we may hereafter resort to operative procedures at an earlier day, and with greater prospects of success. No case like this ever gets well, unless nature or art, or both united, establishes a timely fistulous opening to relieve the gall-bladder of its contents, and thereby restore the channel for the bile. Now, what I propose is this. Whenever we have persistent jaundice, with clay-coloured stools, nausea, and intense itching of the skin, we may take it for granted that there is mechanical obstruction of the gall-ducts, and it is our duty to open the abdomen and search for the gall-bladder as soon as we can detect any swelling in the region of the liver. If we find a dropsy of the gall-bladder, we should deal with it as I have already indicated. If we have been mistaken in our diagnosis, then we have made a simple exploratory incision, which, under antiseptic precautions, is devoid of danger. I would extend the principle of exploratory incisions to other affections of the liver. We know that abscess of the liver is a very dangerous and often fatal disease. It sometimes bursts into the peritoneal cavity, causing rapid death from shock and peritonitis; again, it makes its way into some portion of the alimentary canal, or comes to the surface through the abdominal walls, or passes upwards through the lungs, simulating consumption; while, again, it destroys its victim by pyæmia before it can find an outlet by the slow process of nature. Only three years ago, one of the great statesmen of my own country died of abscess of the liver that made its way through the lung, and it was supposed that he had consumption till a *post mortem* examination revealed the true nature of the disease. And, about twenty-five years ago, one of the most eminent of American surgeons, hardly second to our illustrious Mott, died of pyæmic abscess of the liver, which was discovered only after death. With antisepticism and aspiration, it would now be possible to give relief to such cases when correctly diagnosed.

In cases of suspected abscess of the liver, I propose to make an exploratory incision, to introduce the fore and middle fingers, the hand, if necessary, to examine the liver minutely by the touch above, below, and in all directions; and, if we find fluctuation anywhere, to pass in a Dieulafoy trocar and evacuate the abscess. This I should expect to do with the same ease and the same impunity that belong to the exploratory incisions that we constantly make in doubtful ovarian tumours.

The great lesson that this case teaches is this. In dropsy of the

gall-bladder, in hydatid tumours of the liver, in suspected abscess of the liver, and in gall-stones, we should not wait till the patient's strength is exhausted, or till the blood becomes bile-poisoned, producing hæmorrhages, but we should make an early exploratory incision, ascertain the true nature of the disease, and then carry out the surgical treatment that the necessities of the case may demand. If this should be done under antiseptic precautions, I am sure that much suffering will be relieved, and many valuable lives saved that would otherwise be lost. Without Listerism, the operations I here propose would be hazardous; with it I believe them not only feasible, but perfectly justifiable.

## THE MENSTRUAL SECRETION: INCLUDING CRITICAL REMARKS ON THE PATHOLOGY OF RETAINED MENSTRUAL FLUIDS IN THE ORGANS OF REPRODUCTION.\*

By GEORGE HARLEY, M.D., F.R.S.

As there is almost more danger to medical literature from its becoming overburdened with false facts than with false theories, the interesting report of Mr. Lawson Tait's case, entitled *Menstrual Fluid Retained in the Left Falopian Tube, simulating Ovarian Tumour*, in the to-day's number (May 11th, page 677) of the *BRITISH MEDICAL JOURNAL*, induces me to call attention to certain "facts" concerning the physiological function of menstruation in the human female; a due consideration of which may, perhaps, induce Mr. Tait to somewhat modify the title of his very interesting case of retention of the menstrual fluid in the organs of generation.

The critical remarks I am about to make are entirely offered in a spirit of friendly criticism, and will, I trust, be received in an equally friendly spirit.

Not being a surgeon, I do not intend to review Mr. Tait's case from an operative point of view; but solely from the stand-point of a scientific physician; and, if I er in my judgment regarding the point of doubt, I shall be very pleased to have the error pointed out, and corrected by any one who may chance to be better versed than I am in the subject under consideration.

In order that the points of doubt shall be made perfectly clear, and the arguments stated in the fewest possible number of words, I shall put forward the case in a categorical form.

1. From the description of the pathological condition of the uterine organs, as well as from the tenor of the general remarks made by Mr. Tait throughout the paper, there can be no doubt that it was a veritable case of retained menstrual fluid in the organs of reproduction. But,
2. There exist many grave physiological reasons for doubting the justice of the author's assertion, that the fluid was retained in the left Falopian tube.

3. On the contrary, I imagine that the menstrual fluid evacuated by Mr. Tait did not come from the left Falopian tube at all; but from the uterus itself. And moreover, if he is correct in stating that the "organ" from which the liquid came was left-sided, I think it is not beyond the possibility of exactitude that the case was one of double uterus, and that the fluid was retained in and evacuated from its left cornu.

In order to show explicitly the grounds upon which I venture to propound this view, I shall ask, and answer, the three following pertinent questions:

- A. What is the normal function of the human Falopian tubes?
- B. What parts of the female organs of generation secrete the menstrual fluid?
- C. What parts of the organs of generation are most likely to have their orifice or orifices occluded, and thereby become a receptacle for secreted, but non-excreted menstrual fluid, which might in due course admit of removal by surgical interference?

The replies to these three questions I shall now proceed to give in precisely the same categorical form.

A. No menstrual fluid (proper) is secreted by the Falopian tubes. The function of the Falopian tubes is simply passive, in so far as the function of menstruation is concerned; that is to say, the part played by the Falopian tubes, during the menstrual period, is precisely the same as the part played by the ureters during the process of urinary excretion. They are mere channels of elimination, and nothing more. The Falopian tubes are the ducts along which the ova are floated from the ovaries to the uterus. The ureters are the ducts along which the urine flows from the kidneys to the bladder; so that the passive func-

\* This article is written according to the new method of spelling words, without encumbering them with needless duplicated consonants.

tions of both sets of ducts are precisely the same, viz., that of mere channels.

2. The menstrual fluid of the human female consists of three distinct parts: *a.* The ova; *b.* The fluid of the ovarian vesicle in which the ova are developed; *c.* A sanguineous discharge from the uterine mucous membrane. These three, combined, go to form what is known under the title of the menstrual secretion. I permit myself to speak authoritatively on this point, as I once enjoyed an opportunity of studying the physiological function of menstruation on a woman, who committed suicide when on the very brink of menstruating, such as no man, as far as I am aware, ever similarly enjoyed. The condition of things then found was carefully delineated in water-colors, by a professional artist, and still exist in all their pristine exactitude to verify every word which I am now about to say.

A healthy married woman, of twenty-three years of age, in a fit of jealousy, drowned herself in the Serpentine in 1861. At the time, the scientific comitee, appointed by the Royal Medical and Chirurgical Society, was actively engaged in the investigation of the best means of resuscitating the apparently drowned. As a member of that comitee, I had occasion to make the *post mortem* examination of the young married woman just mentioned; and, although the woman's organs of generation had nothing whatever to do with the question of suspended animation—as I was at the time in question lecturing to the students of University College on the subject of reproduction—after finishing the necropsy, in as far as the pathological appearances of drowning were concerned, I turned my attention towards the woman's organs of generation, when, to my surprise and delight, my eye caught sight of the congested surface of an ovarian vesicle, distended with fluid, of the size of a large hazel-nut projecting beyond the exterior of the left ovary. Although not then fully conscious of the invaluable specimen which accident had thrown in my way, I carefully extracted the whole group of the internal organs of reproduction, and conveyed them, for subsequent scientific investigation, to the Physiological Laboratory of University College, which was at that time under my immediate superintendence. On examination, the immense value of the specimen at once became apparent.

The uterus, which was a "virgin one", was found slightly congested, and towards its internal fundus was a vascular, engorged, puffy portion of the mucous membrane, covered over by a thin adherent layer of sanguineous mucus—more blood than mucus—and from it, extended downwards to within half an inch of the os uteri, a conical-shaped layer of blood; not a single drop of which had, however, as yet reached the internal orifice of the os. The true state of matters at once dawned upon my mind; and accordingly, I at once transferred my attention to the ovaries, both of which were slightly congested. On the surface of the left ovary was seen an ova-follicle, all ready to burst. Had I doubted that the follicle was on the very verge of bursting, the sequel would soon have undeceived me. For while I was handling it, and that tenderly too, it burst beneath my fingers, and from it flowed a whitish serous liquid, which was instantly carefully collected and microscopically examined. One ovum alone was detected in it. The condition of the Fallopian tubes was next inquired into. The fimbriated extremities of both were found to be highly congested—much more so, externally, than either the external coat of the ovaries or of the uterus. But the internal coat of the tube was perfectly free from any trace of congestion whatever; and, by its pale white, shiny tendinous appearance, formed a very marked contrast to the highly congested lining mucous membrane of the uterus, the congested radius of which abruptly ended at the very orifice of the uterine ends of the Fallopian tubes. Strange to say, it was actually at the margin of the Fallopian tube orifices that the congested appearance of the mucous coat of the uterus was most marked. It may not be here out of place, incidentally to mention, that the right ovary contained a well-defined, non-impregnation, corpus luteum (commonly called false corpus luteum), as well as a beautiful, congested, unripe, ovum follicle, of the size of a large pea, embedded in its interior.

From these facts, as facts they undoubtedly are, I venture to propound the following theory as regards the normal function of human menstruation.

1. The menstrual fluid, as already said, consists of three perfectly distinct parts: ova, white serous ovarian-follicle secretion, and sanguineous mucus uterine secretion.
2. The ovaries and the uterus are the only parts which supply the menstrual secretion.
3. The Fallopian tubes do not secrete any of the ingredients special to the reproductive function.
4. The Fallopian tubes are mere passive canals for the transport of the secretion of the ovaries into the uterus.
5. No sanguineous menstrual fluid whatever enters the Fallopian tubes, in a normal state. If it gets there at all, it can only be from the uterus by an abnormal condition of regurgitation.

If this theory of normal menstruation be correct, it follows, as a natural sequence, that Mr. Tait erred in supposing the menstrual fluid that he evacuated had been pent up in a distended Fallopian tube. In case he should, however, still entertain any doubt on the subject, I shall now proceed to quote passages from his own paper, which are in direct confirmation of my views.

1. He states that the tumour "presented the red muscular appearance of the uterus".
2. A fragment of the tissue of the tumour, when subjected to microscopical examination, "proved to be composed of an abundance of unstriated muscular fibre".
3. "After the cyst was emptied", it contracted round and grasped the finger.
4. He "could find no canal leading into the uterus".
5. "About six quarts of thick dark-brown fluid, having the peculiar smell of menstrual fluid", were evacuated by means of a trocar.

These facts, taken in conjunction with the physiological description I have just given of the female organs of generation, as they appear at the menstrual period, seem to my mind to warrant the acceptance of one of the following theories regarding the source from which the grumous fluid was evacuated: namely, that the fluid was actually evacuated from a normal or from an abnormally formed uterine cavity. A. Because a grumous dark-brown fluid, posing a distinct menstrual odour, could not have readily existed at any other point of the reproductive organs above the os uteri. B. Because an occluded os uteri is not an unknown pathological condition.

Lastly, as the patient was an unmarried lady, thirty-eight years of age, and presumably a virgin; and as Mr. Tait distinctly states that it was from an organ on the left side of the body that the fluid was evacuated; it is by no means impossible that the patient was the subject of a double uterus, and that it was in the left occluded cornu of the uterus that the pent-up secretion was retained. This latter view is the one which accords most intimately with the description which Mr. Tait has given of the anatomical relations of the parts; and, had he only given as well a general history of the patient's catamenia, from the time of their first appearance up to the date of the operation, this theory could almost have been reduced to an axiomatic certainty, or the reverse.

## SOME INDICATIONS FOR THE DIAGNOSIS AND TREATMENT OF AORTIC ANEURISM.\*

By F. A. MAHOMED, M.D.,

Medical Registrar to Guy's Hospital; Assistant-Physician to the London Fever Hospital; etc.
